In 1860 Seward was a candidate for the presidential nomination, but on failing to receive it gave his hearty support to Lincoln, whose cabinet he entered as Secretary of State, an office which he held through two administrations, from 1861 to 1869. The civil war, which was in progress during the first half of this period, rendered the foreign relations of the United States unusually delicate, especially in view of the attitude of the governments of France and Britain. In the 'Trent' affair he was obliged, in opposition to popular clamour, to admit the justice of England's claim and to advise the president that the Confederate envoys should be given up. He protested against the fitting out of the *Alabama* and similar vessels in British ports, and declared that the United States would claim from the English government indemnities for damages resulting from this breach of the obligations of a neutral power. On the subject of the French invasion of Mexico he maintained a prudent reserve, until the conclusion of the war enabled him to insist on the withdrawal of the French troops. On April 14, 1865, while confined to his bed with a broken arm and jaw, the results of a carriage accident, he was attacked and severely cut on the face and neck by an accomplice of J. B. Booth. He supported President Johnson's reconstruction policy, thereby placing himself in opposition to the majority of his own party and incurring much bitter censure. In 1867 he negotiated with Russia the treaty for the purchase of Alaska. After leaving office he

travelled in 1869 to California and Alaska, returning through Mexico, where he was warmly welcomed as the guest of the nation; and in 1870-71 he made a tour round the world, his narrative of which was edited and published (1873) after his death by his adopted daughter, Olive Risley Seward. He died at Auburn, 10th October 1872. Without being a creative statesman, Seward had great practical ability controlled by sound notions of truth and justice; always a party man, he was never an extreme partisan, and rather made public opinion than followed it. Strong convictions joined to a conciliatory disposition rendered him a fitting representative of the moderate anti-slavery sentiment and a worthy fellow-worker with Lincoln in preserving the Union.

See his Autobiography, continued to 1846 in a memoir by his son (1877), and to 1872 in his *Life and Letters* (2 vols. 1891); *Life by the same* (3 vols. 1895); also C. F. Adams's *Address on his Life, &c.* (1873), the memoir by G. E. Baker, with his *Works* (3 vols. 1833; 2 other vols. 1862-84); the *Life* by F. Bancroft (1900); and by E. E. Hale (1911).

Sewellel. See HAPLODON.

Sewerage is the term applied to the whole process of the collection and removal of the liquid and solid excrements of men and animals, the washings from the streets and slaughterhouses, the waste waters used in cleansing operations, the contents of baths, basins, and sinks, and the organic liquid refuse from certain manufactories, together at times with a quantity of rainfall. It involves, therefore, the problem of the design of house sanitary fittings, the lay out of house drains and their connections to the sanitary fittings, the construction of the sewers or channels for conveying the discharge from the house drains, the washings from the streets and all other fouled water technically called 'sewage' to the outfall works, and, finally, in the case of inland districts, the whole of the processes for the purification of this sewage prior to its final discharge into a river.

The most important of the sanitary fittings which require to be provided in a house are baths, basins, sinks, and water-closets, and special care must be devoted to the design of each of these fittings in order that they may properly fulfil their purpose and be, as far as possible, self-cleansing. The old plan of enclosing these fittings with wood-casing is most insanitary; baths, whatever material is employed in their construction, should be supported on short legs, so as to permit free access for cleaning to every part of the bath and to the adjacent walls and the floor beneath. For similar reasons all basins and sinks should be supported by some form of attachment to the walls; water-closets generally rest upon and are secured to the floor, but in hospitals it is desirable to adopt a form of water-closet which can by means of lugs be supported directly from the wall without any attachment to the floor, thus allowing the floor of the lavatory to be kept rigorously clean.

Various types of water-closets are in use at the present day, and all of those described below have been found by experience to be more or less satisfactory from a sanitary point of view; these types may be classified under the headings of wash-down, siphonic, wash-out, and valve. The wash-down (fig. 1) is perhaps the form most generally used; it is not expensive to make, is simple in construction, and has no working parts likely to get out of order when in use. The siphonic type (fig. 2) is one in which the contents of the pan are discharged by siphonic action, and the trap is refilled by an after-flushing device. The wash-out closet (fig. 3) has certain serious disadvantages when compared with the wash-down types, the

standing water in the pan is too shallow, and it is difficult to secure a complete clearance of the contents of the pan by the ordinary flush, and even when this is attained the trap is frequently not cleared properly. The valve-closet (fig. 4), although it has mechanical devices not present in any of the other types which have been described, is on the whole a most satisfactory type for use in

domestic houses and in other situations where closets are not subjected to possible rough usage.

An important attachment to any water-closet is the flushing cistern (fig. 5), a water-waste prevention device which automatically allows only a known volume of water—two gallons or three gallons—to be used for each flush of the pan of the closet. It consists of a small tank, fixed gene-

Fig. 1.—Wash-down W.C.

Fig. 2.—Siphonic W.C.

Fig. 3.—Wash-out W.C.

ally at a height of four or five feet above the closet, and connected to the latter by means of a pipe of at least $1\frac{1}{4}$ inch diameter. The flushing water is released by pulling a chain which sets in action a siphon and allows the flushing water in the little tank to pass into the connecting pipe; the tank is then again automatically refilled, a ball-valve cutting off the supply as soon as the necessary volume of fresh water has entered the tank. The flushing cistern must be distinct from any cistern containing drinking-water, and must be provided

with an overflow pipe led away to an external outlet.

Between every sanitary fitting and the waste or soil pipe into which its contents are discharged there must be interposed a trap of simple construction (fig. 6) which holds always a certain amount of water and thus prevents the passage of foul air from the waste or soil pipe into the house. The depth of the water-seal should be great enough to prevent the risk of unsealing the trap by evaporation of its contents under any circumstances, a depth of

Fig. 4.—Valve-closet.

Fig. 5.—Flushing Cistern.

Fig. 6.—Trap.

about 2 inches is enough for this purpose. The traps of sanitary fittings may also be unsealed by siphonic action when several fittings are attached to the same waste or soil pipe, especially when these fittings are situated on different floors of the house. This siphonic unsealing is due to the discharge of one fitting tending to cause a partial vacuum in the branches connected to other fittings, and thus tending to cause the water in the traps to be sucked out. To prevent this action most sanitary authorities insist that every trap shall be ventilated by the use of what is called the 'anti-siphon' pipe. This anti-siphon pipe is a vertical pipe fixed to the wall side by side with the waste and soil pipes, open at its upper end, and connected by a short branch to each trap just beyond the highest point of the trap on its discharge side. In the London County Council bylaws, for example, it is provided in the case of water-closet traps that the connection to the anti-siphon pipe shall start from a point on the trap not less than 3 inches and not more than 12 inches from the highest point of the trap on its discharge side. The discharge from

water closets and urinals passes into what is termed the soil pipe, the pipe receiving the discharge from other fittings being termed a waste pipe; this latter pipe does not discharge direct into the house drains, but into a gulley trap from which the contents pass into the drain; on the other hand the soil pipe is connected direct to the drain, no trap being interposed. The waste pipes, which are preferably fixed to the outside walls of the house, are of lead, iron, or stoneware, and they discharge into the open air above a gulley trap. The soil pipes, if fixed internally, should be lead with wiped joints; if fixed to external walls, they are usually cast-iron or lead.

House Drains.—These are usually glazed stoneware pipes, varying in diameter from about 4 inches to 9 inches; for an ordinary house it is rarely necessary to exceed 6 inches in diameter for the main discharge pipe and 4 inches for the single branch lines taking the discharge from the respective fittings. The pipes are usually 2 feet in length, of the socket and spigot type; to join two successive lengths, the spigot end of the one is pushed into the socket end of the other, maintained in a truly central position by a little gasket thrust into the gap between the inside of the socket and the outside of the spigot, and then the whole of the rest of this space is carefully filled with neat

Portland cement mortar. This is a somewhat rigid type of joint, and there are several other well-known types of patent joints employing bitumen or some such similar material, which give greater flexibility to the line of pipes and allow a small settlement to take place without risk of injury to the joint and the possibility of leakage at the joint. In order to lessen the risk of settlement of the line of pipe and resultant fractured pipes or joints, the pipes should not be laid direct upon the earth at the bottom of the trench, but upon a bed of concrete at least 6 inches thick, well benched up at the sides of the pipe. When stoneware drains pass under a house—a very undesirable practice—they should be entirely surrounded with concrete at least 6 inches in thickness.

Instead of stoneware, cast-iron pipes are often employed for house drains; they have certain advantages—they are much stronger and therefore less liable to fracture, they are made in lengths of 6 and 9 feet and therefore have many less joints, the joints are made with molten lead instead of with Portland cement. They should always be employed when the drains pass under a house.

The drains should, as far as possible, be laid in straight lines, and, wherever a change of direction is necessary, good bends should be provided, so as to change gradually the direction of flow. Whenever a junction with a branch pipe occurs, or a change in direction, inspection brick chambers should be provided, with open half-pipes in the chamber instead of closed pipes; this provides access to the different lines of pipes and allows drain-rods to be used for clearing stoppages; the half-pipes at the bottom of the pit should be benched up, so as to allow the liquids which may overflow the edges of the half-pipes to pass quickly away from the chamber when the rush of water has ceased. In order to secure a sufficient velocity of flow in the drains to carry forward all solid matter that might remain in the pipes and decompose, all drains must be laid with a sufficient gradient which, as far as possible, should be uniform from end to end. For a 6-inch pipe a gradient of 1 in 80 is about the minimum permissible—this will give a velocity of about 3 feet per second; generally, the gradient in drains will vary from about 1 in 80 to 1 in 100.

It is generally specified that just as the indoor and outdoor house pipes are disconnected by the interposition of a trap, so too the main discharge drain should be disconnected from the sewer by a special form of trap known as the disconnecting trap (fig. 7). This trap should be placed as near as possible to the point where the drain joins the sewer, and it should always be placed in an inspection chamber or manhole. This trap makes it practically impossible for sewer-gas to pass into the house drains with the risk of dangerous gases finding their way into the house. The inspection chamber containing this disconnecting trap must be adequately ventilated, and should be covered with a cast-iron cover fitting into a cast-iron frame with grooves, so as to seal the chamber.

Testing of Drains.—After the drains have been laid and the various joints have been made, the whole system must be thoroughly tested for water-tightness before refilling the trenches in which the pipes have been laid; care should be taken, however, not to make this test too soon after the completion of the jointing operations, as time must be given for the cement joints to set hard—about two days is sufficient for this. There are several methods of making this test—the most searching test is that of water pressure; for this purpose the lowest end in the drain is closed by a rubber stopper, then the top end may be closed and water pumped into the pipe system until a

predetermined pressure is reached, a pressure-gauge is fitted to the apparatus, and when this gauge shows the desired pressure is reached the pumping is stopped and the gauge is watched—if the reading of the gauge remains steady, then it is known that the pipe system is water-tight and the work of laying and jointing has been carried out satisfactorily. For stoneware pipes the test pressure should not exceed that due to 5 or 6 feet of water, or about $2\frac{1}{2}$ lb. per square inch; in the case of cast-iron pipes the pressure may be as high

Fig. 7.
Disconnecting Chamber.

as 9 lb. per square inch, which is equivalent to about 20 feet of water. The necessary water pressure may be obtained without the use of a pump by attaching to the top end of the drain system a vertical pipe into which water can be poured up to the necessary depth to secure the required pressure. Instead of water, air may be pumped into the system, but it is not quite so easy in this case, if there are defects, to locate the leak or defect. To test the vertical waste and soil pipes, either the smoke or the smell test may be employed, as in such pipes a water test is liable to put undesirable stains upon the joints. To carry out the smoke test the ends of the pipe are closed, and by the use of a smoke-rocket or similar device volumes of thick smoke are forced into the pipe, any leak or defect at once becomes apparent by leakage of smoke from a pipe-joint into the air or from one of the fittings, and the exact spot at which the escape takes place is apparent at once. In the case of the smell test, a chemical such as oil of peppermint, which gives off a powerful odour, is introduced into the pipe, generally through one of the traps connected to the pipe system under test. It is difficult, however, with this method of testing to locate the position of the defect if there is one. All traps should be thoroughly tested by pouring a good stream of water through the fitting attached to the trap and observing whether unsealing by siphonage or other cause occurs in the trap or in any other trap in the system.

Dry Earth-closets.—The water-carriage system, though undoubtedly the best, is a costly one to instal with all the necessary pipes and traps. In country districts and in villages the water-closet may still be used, but with its discharge passing direct to closed-in cesspools, situated at some distance from the house, or preferably some form of earth-closet may be employed, though this latter system means that the closet should be

outside the house. The dry earth-closet system (fig. 8) was due to the Rev. H. Moule, who took out a patent for it in 1860; in this closet the faecal matters are deodorised by the application of dry earth or ashes; it is essential that the earth employed should be of a loamy character, perfectly dry and finely sifted. There are many forms of the earth-closet in which the earth is automatically thrown into the receptacle after every use of the closet, but on the whole it is better to apply the earth by hand by means of a scoop from a box of suitable earth kept in the closet. Under this system the contents of the receptacle are removed at regular intervals and dug into the ground. The dry earth-closet only provides for the removal in a

Fig. 8.

A, door-opening for filling hopper; B, door for emptying tank; C, shield; D, slide.

sanitary manner of faecal matter, all other sewage waste has to be disposed of by other means, and the use of this system in any adequately sewered district is therefore undesirable.

Sewers.—The pipes into which the private drains of all the houses and other buildings discharge their contents are known as sewers, and are the property of the local authority; all connections with the public sewers are made under regulations laid down by the local authority, whose duty it is to provide and maintain an adequate sewer system capable of carrying off all the dry-weather sewage-flow from houses and factories, and, in general, also of a larger or smaller quantity of the rainfall over the district the authority controls. The sewers may be designed on the combined system, in which case they must have a capacity large enough to convey not only the dry-weather sewage flow, but also quite a considerable proportion of the water due to the rainfall over the district; or they may be designed on what is termed the separate system. In this method there are two sets of independent sewers—one which has to deal with all the dry-weather sewage flow plus a small proportion of the rainfall, namely, that which falls on the backyards of houses and similar places; the other, which deals with rain-water only, carrying off a considerable part of the rainfall upon the whole of the rest of the area of the district. There is a considerable difference of opinion on the part of sanitary engineers as to the respective advantages

and disadvantages of these two systems, though it is indisputable that it is a distinct advantage to exclude as much as possible of the rainfall from the ordinary sewer, especially when consideration is paid to the question of purification works, when these are necessary. In the case of towns and villages situated directly on the open coast, this question of the exclusion of rainfall from the sewers is not a matter of such importance, except in so far as it may affect the first cost of the works by making it necessary to adopt larger cross-sectional dimensions for all the sewers.

Street sewers, when of moderate capacity, are usually circular pipes of glazed stoneware or cast-iron, varying in diameter from about 6 inches to 24 inches. The methods of jointing are similar to those already described for house drains—that is, for stoneware pipes, cement or some form of patent jointing; for cast-iron pipes, the ordinary melted lead joint. The same precautions have to be adopted as in house drains to maintain the necessary gradient to ensure a velocity of not less than $2\frac{1}{2}$ feet per second, in order that solid matters may be carried forward and not allowed to remain in the sewer to undergo putrefaction; further, the sewers should be laid, as far as possible, in straight lines, every necessary change of direction being made gradually, with suitable bends. Manholes must be provided at all junctions and changes of direction, and adequate arrangements must be made for thorough ventilation.

When the quantity of sewage to be conveyed is greater than can be dealt with by a 24-inch diameter circular pipe with the velocity of flow given above, built-up brick or concrete sewers must be employed. These built-up sewers are sometimes circular in section, especially when reinforced concrete is employed in their construction, but more usually they are egg-shaped, the invert of the sewer being of a much smaller radius than that of the upper portion. The egg-shaped form is of advantage when it is remembered that the volume of flow through any sewer is subject to wide variations due in part to the influence of occasional rainstorms, and also due to the fact that a considerable portion of the whole dry-weather flow has to be dealt with in the 12 hours from 7 A.M. to 7 P.M. The Chezy formula for the velocity of flow in any pipe or channel, $V = C\sqrt{m}$, indicates, other things being the same, that a good value of m (the hydraulic mean depth) means a higher velocity of flow, and, in an egg-shaped sewer, a larger mean depth is secured when the quantity of liquid passing down the sewer is smaller than would be obtained for the same volume of liquid with a true circular cross section. The egg-shaped section (fig. 9) has usually a ratio of invert depth to width of block section of 3 to 2.

These built-up sewers can be constructed entirely of brick-work, the inverts being separate blocks of glazed stoneware or similar material, the mortar used being Portland cement. In wet ground, to keep out subsoil-water, the brick-work may be coated on the outside with neat Portland cement mortar, or some bituminous composition. The thickness of brick-work employed will

Fig. 9.—Egg-shaped Sewer.

depend partly upon the cross-sectional dimensions of the sewer and partly upon the depth of the trench in which the sewer is laid—that is, upon the depth of earth covering. If the sewer is less than about 3 feet in diameter, laid in a trench with a depth not exceeding about 20 feet, a thickness of 4½ inches is sufficient if it is well backed with concrete; for larger sized sewers and deeper trenches it is well to use a thickness of 9 inches. Concrete is another material largely used for sewer-work, generally in conjunction with brick-work, but frequently alone; but in this case it is most desirable to use what is termed reinforced concrete—that is, concrete in mass, with steel bars embedded in the concrete in such positions as to make it certain that these steel bars will take up all tensile stresses.

If the materials used in constructing a sewer decay, or if the sewer joints begin to leak, there is danger of the ground upon which houses are built being fouled; hence comes pollution of the ground-water and the outbreak of various diseases. The bricks used in the construction of all sewer-work should be as impervious as possible, and, as a rule, no bricks should be allowed to be used in sewer-work in which the absorptive capacity for water exceeds 12 per cent of their dry weight. The materials used in the jointing of brick sewers should also be of the most permanent character, and no better material than Portland cement mortar has yet been discovered which will resist the chemical action of sewage upon it. The materials used and the design adopted must be such as will allow of contraction and expansion by change of temperature. In the case of house drains the changes of temperature are much more considerable than in the case of sewers, as often in house drains water almost at the boiling-temperature may at one time be passing through the drain, and at another melted snow. These changes of temperature affect the stability of all sewer-work, and tend to pull it to pieces. The joints, therefore, should be of such a character, if possible, as not to present too much resistance to slight movements, and should be parallel, so that if the pipes move by contraction or expansion the joints will not open more at one point than at another. For this reason the ordinary socket-joint, when properly made, is found to be one of the best joints for either sewers or drains.

The size of sewers must be determined from consideration of the population of the district, the volume of dry-weather sewage per head of population, the fluctuation in the daily flow from hour to hour, the amount of the rainfall which is carried off by the sewers, and the fall which can be given to the sewers. The volume of the dry-weather flow may be assumed to be equal to the water-supply, though in certain cases this may be considerably increased by the fouled water of manufactories in the district deriving their water-supply from independent artesian or sub-artesian wells. The water-supply per diem per head of the population varies greatly in different towns—even in the case of towns having populations engaged in similar industrial occupations; while in small towns the daily allowance may be as low as 20 gallons, in large cities it often exceeds 45 gallons, though a greater daily supply than this last figure is hardly necessary for hygienic purposes in temperate climates. For approximate calculations, 30 gallons per head per diem may be taken as an average figure in this country.

The allowance for surface-water due to the rainfall is much more difficult to determine with accuracy, and sanitary engineers differ widely in their estimates of the allowance which should be made for water passing into sewers from the rain-

fall. While the actual rainfall is usually known very accurately, and its distribution throughout the year, and also the rate at which rain falls in short-lived storms of exceptional violence, the difficulty is to decide how much of this rainfall will find its way into the sewers. When the Metropolitan (London) sewers were originally designed, they were built to carry off a dry-weather flow of 5 cubic feet per head per diem and a rainfall of 0.01 inch per hour in urban and 0.005 inch per hour in suburban districts. This estimate of the rainfall sewage was worked out on the assumption that five-eighths of the total rainfall in urban districts would reach the sewers; it allowed, therefore, for a rainfall of 0.4 inch per diem. Under these conditions the maximum discharge allowed for was about four times as great as the dry-weather flow. In the city of Berlin the estimate was that the maximum rainfall in an hour was $\frac{1}{2}$ inch, and that one-third of this would pass into the sewers. These two examples show the wide variation in the allowance for rainfall sewage.

In determining the size of the sewers it must be remembered that considerable relief can be given to the sewers from the effects of sudden heavy rainstorms by the use of storm-water overflows. In the case of London, already referred to, the estimate at that time was that on from fourteen to twenty-one days in each year the sewers would be incapable of dealing with the rainfall water which would reach them, but this was met by providing a series of storm-water overflows discharging direct into the Thames. Under the Ministry of Health regulations, storm-water overflows are not allowed to come into operation until the total flow of storm-water and sewage equals six times the average dry-weather flow. To avoid all risk of the flooding of sewers, the engineer must consider each street in which there is a sewer independently, and calculate for that street as exactly as possible the probable amounts of rain-water due to the average and to exceptional rainfalls which would pass into the sewer, determining accurately beforehand the area of paved and unpaved surfaces the rainfall upon which must pass into that particular sewer. The whole calculation is a laborious and troublesome piece of work, but it may be stated at once that upon the thoroughness with which this work is done will depend the future success of the sewerage system as a whole. The effect of rainfall upon the volume of sewage flowing in the sewers may be more severe in the several district sewers than in the main outfall sewer, owing to the fact that in a large district the additional volume due to the rainfall in the more outlying areas has to traverse a considerable length of sewer before it reaches the main outfall sewer.

There is a daily fluctuation in the dry-weather flow, and this has to be allowed for in designing sewers; gaugings of the flow in sewers in various towns show that about 60 per cent. of the twenty-four hours' flow may pass into the sewers in the twelve hours from 7 A.M. to 7 P.M., and that between 6 and 7 per cent. may pass into the sewer in one hour.

When the volume of sewage to be dealt with, making allowance for all the factors mentioned above, has been determined, the mean velocity of flow in the sewer must be decided upon; in order that solid matters may be carried forward by the flow of the liquid in which they are suspended, in other words in order that a sewer shall be self-cleansing, a mean velocity of at least 2 feet per second must be secured, and, better still, 2½ feet per second. To maintain the velocity selected, the sewer must be given sufficient fall or gradient, and the simplest formula upon which the

necessary calculations can be based is the well-known Chezy formula, $V = C\sqrt{mi}$, where V is the required velocity of flow in feet per second; m is the hydraulic mean depth of the stream in the sewer, or the ratio of the area of the cross-section of the stream to its wetted perimeter, which, in the case of a sewer circular in cross-section, is $\frac{d}{4}$ when

the stream fills the sewer or when it is half-full; i is the gradient or fall in feet for a given length of sewer; and C is a coefficient, which depends upon the material out of which the sewer is constructed and the roughness of its interior surface. Valuable tables have been published to facilitate these calculations for various ratios of C and i . It sometimes happens that the contour of the ground is such that a sufficient gradient cannot be obtained to maintain the mean velocity required for a self-cleansing sewer, in which case pumping must be resorted to to lift the sewage from a low level to a higher level. It may be necessary to divide a town into a number of sections; smaller sewers with rapid falls convey the sewage quickly from the various sections to a number of different points, and from these points it is pumped into one main delivery sewer. There are several automatic systems for carrying out this pumping work, such as the hydraulic system, the electrical system, and the Shone system.

In the hydraulic system, at some convenient centre in each section, an automatic hydraulic pumping station is established to which the sewers of the section gravitate. A central power station is established, at which by steam or some other source of power high-pressure water is obtained by pumping low-pressure water into an accumulator. From the accumulator pipes are laid to the various automatic pumping stations in the districts into which the town has been divided. The automatic hydraulic engines at the various local stations are simply direct-acting pumping engines, in which the high-pressure water gives motion to a piston within a cylinder, and this in turn works a pump directly attached to it. The automatic engines are controlled by a float in such a way that when there is sewage to pump it is pumped just as fast as it flows in from the sewer, and when the flow of the sewage from the sewer declines, the hydraulic engine stops until the supply of sewage is replenished. The water used to transmit the power from the power station is usually under a pressure of 700 lb. per square inch, and the advantage of this system is that the loss of power during distribution is very small—in this respect water compares very favourably with air as a means of power transmission. Another advantage in this system is that, by varying the diameters of the hydraulic engines, sewage can be lifted to variable heights at the various sections, although all the plants are supplied with water at the same pressure; it is also easy to store up reserve power in the accumulator, ready for any sudden demand for additional pumping without in any way increasing the water pressure. The water that has been used for transmitting power, after it has done its work, may be used for flushing the sewers, as it may be delivered from the cylinder exhaust to automatic flush tanks, thus saving the cost of purchasing water for flushing purposes. This system is possibly more economical than any other system, when all its advantages are taken into account—it occupies a small space at the automatic station, a plant big enough to deal with $1\frac{1}{2}$ million gallons of sewage per day can be accommodated in a cylindrical chamber 9 feet in diameter, which can be constructed below a public roadway. The system has been adopted in a number of towns.

The electrical system differs from the hydraulic

system in two important details—power is conveyed from the central power station to the automatic pumping station by electric cables, and electric motors take the place of the hydraulic engines. The motors are started and stopped, as in the case of the hydraulic engine, by means of floats, and the plant is even more compact than the hydraulic. Most of the pumping of sewage has to be done in daylight hours, a time when an electric power station is usually prepared to sell its electric energy for power purposes at a specially low rate per unit.

The Shone system is a pneumatic one, air above atmospheric pressure is applied directly to the liquid sewage contained in an iron vessel called an ejector, and the direct pressure of the air forces

Fig. 10.—Shone's Pneumatic Ejector.

the sewage out of the ejector (fig. 10) to the required altitude. The air under compression is admitted to and cut off from the ejector automatically, so it is self-acting, like the two other systems already described. This system requires, like the hydraulic system, a central power station where the air is compressed into receivers, from which it is distributed by pipes to the various points at which the ejectors are set up.

Ventilation of Sewers.—Sewer-gas, as it is called, is caused by the fouling of the air by its admixture with the various gases which are given off during the decomposition of the sewage flowing through the sewer; to reduce the dangerous character of sewer-gas, it is necessary to mix it with an abundance of good fresh air, and, therefore, adequate ventilation must be provided in every system of sewers. Ventilation may be provided by means of open pipes carried up well above the level of the tops of the neighbouring houses; where there is no intercepting trap on the main drain from a house, the soil pipe of the house serves as a sewer ventilator. Another simple method is by building vertical shafts from the sewers to the level of the road-surface, and covering these shafts with metal gratings, the shafts themselves being built of brick-work set in cement. Under each grating is a trap or other device for catching dirt that may pass through the grating, and sometimes trays of charcoal, over which the gases have to pass before

escaping into the street. The dry charcoal decomposes the H_2S and ammonia, and renders the gases quite harmless and odourless.

The Disposal of Sewage.—This is one of the most important points for consideration, as it is no longer permitted to allow the sewage to flow in its crude state into the fresh-water rivers and water courses of the country, as was done when the systematic sewerage of towns was first undertaken. Application of the sewage to land came into prominence about the middle of the 19th century. At first its advocates laid much stress upon the prospect of securing financial profit from this method of purification, and little attention was paid to the possibility of such a process being detrimental to public health. Various Royal Commissions recommended this method of dealing with sewage; and Sir Edward Frankland carried out for the 1868 Commission a series of valuable experiments, using 6-feet high glass cylinders, 10 inches in diameter, filled with various soils, which were dosed with crude sewage twice every 24 hours at various rates—he termed this method ‘intermittent downward filtration.’ This method of applying the sewage to the land was adopted by a number of towns, but due to inattention to important details of the process the results which were obtained were not on the whole very satisfactory. Simultaneously with the development of land purification of sewage, the chemical treatment process of preliminary partial purification was developed and eventually used on an extensive scale. The chemical treatment requires the construction and maintenance of a series of settlement tanks with a total capacity of about 50 per cent. of the normal dry-weather flow, and suitable arrangements for adding the requisite doses of the chemicals employed to the crude sewage before it enters the settlement tanks. In these tanks precipitation occurs of the matters separated from the sewage, and this precipitant, or sludge, as it is termed has to be removed at regular intervals. The chemicals which have been most generally employed are milk of lime—an average dose being about 15 grains of lime per gallon of crude sewage—or milk of lime in a smaller dose followed by either a dose of sulphate of alumina or a dose of proto-sulphate of iron; the latter process was that adopted for the preliminary treatment of London sewage before the effluent was allowed to pass into the Thames at the two outfall points, Barking and Crossness. In the case of inland towns the effluent from the settlement tanks had to be passed over or through land, or through artificial filters, before it was in a fit state to be allowed to flow into any stream or water course. It is now generally recognised that the main result of the application of chemicals is the removal of the suspended matter in the crude sewage, while the substances in solution are only slightly reduced in quantity.

The chemical treatment of sewage produces a considerable volume of a semi-liquid sludge, and the disposal of this sludge is an extremely difficult problem. Various methods of dealing with it have been employed. In the case of London, Glasgow, and a few other cities situated on an estuary, the sludge is conveyed out to sea in specially designed steamers fitted with large internal tanks. When the steamer has reached a suitable place—in the case of London, the Barrow Deep in the North Sea—the sludge is allowed to flow out of these tanks into the sea by opening valves below the water-line; quite a fleet of steamers is required to deal with the sludge obtained from the vast population of London. Ordinary sludge consists of about 90 per cent. of water and 10 per cent. of solids, the quantity of sludge per 1,000,000 gallons of sewage treated when lime alone is used as a precipi-

tant is about 40 tons, and when sulphate of alumina is used in addition to lime, about 60 tons; these figures will show what a serious problem the disposal of the sludge is in the case of inland towns, where the shipment of it to sea is impracticable. Another method of disposal was to run it into trenches previously prepared on suitable land, but this method was liable to become an intolerable nuisance to people living anywhere in the neighbourhood, owing to the foul smells given off by the sludge before the trenches could be covered over with earth after they were filled with the stuff.

By far the most effectual way of disposing of the sludge in the case of inland towns is to pump it into filter-presses, the pumping being done by compressed air. In this way it is rendered dry enough to be handled and easily transported, and at the same time it becomes free from nuisance, as sufficient water does not remain in it to render it offensive and liable to decomposition. As a result of the process of pressing, the weight of the dried residue is only about one-fifth of that of the original sludge, in other words, out of every 5 tons of sludge forced into the filter-presses 4 tons of liquor are forced out, this liquor being allowed to flow back eventually into the settlement tanks. This reduction of the weight is in itself an important advantage of this process, the pressed sludge has about the same manual value as ordinary farm-yard manure, and in some instances its sale for manure purposes in part defrays the somewhat heavy cost of pressing.

Most towns situated on the coast discharge their sewage untreated into the sea; this is done at Edinburgh—the old irrigation system utilising the Craigentiny meadows has now been entirely abandoned, and a new outfall sewer, discharging the untreated sewage directly into the Forth, has been constructed. The dispersion of raw sewage into a large volume of sea-water has a marked purifying effect, and, provided that the outfalls have been so arranged that the tidal currents tend to carry the sewage away from the foreshore, no nuisance is likely to be caused. Sewage has a density less than that of sea-water, and the sewage therefore after it leaves the mouth of the outfall sewer tends to rise to the surface, hence the outfall sewer should terminate, if possible, in fairly deep water. The sewage should, if it can be arranged, be discharged only at ebb-tide; in the case of Portsmouth this was secured by constructing large storage tanks in which the sewage could be collected during the flood-tide and then suddenly discharged in large volumes as soon as the ebb-tide had fairly set in.

Bacterial Methods of Purification.—The modern tendency is to employ this method to the exclusion of all other processes, and an immense amount of research has been carried out during the present century to ascertain the nature and character of the micro-organisms which are capable of breaking down the highly complex constituents of sewage and converting them into harmless substances, thereby producing an effluent which can be discharged with safety to public health into fresh-water rivers and streams. Certain experiments carried out by the Massachusetts State Board of Health in 1889–90 first directed attention to the possibility of adopting entirely new methods of purification of sewage. Lowcock constructed an experimental artificial filter at Wolverhampton about 1893: the filtering material was coke-breeze, the total depth of the filter was about 6 feet, and air was blown into the interior of the filter under a pressure equal to a head of about 45 inches of water. Lowcock found that he obtained a very satisfactory effluent when the dose of sewage was at the rate of about 284,000 gallons per acre of surface per diem.

Between 1892 and 1896 Dr Dibdin carried out a series of experiments at the outfall works of the London sewage system at Barking; he used artificial filter-beds of about 3 feet in depth, with coke-breeze as the filtering material; the beds were worked in the following manner: the bed was slowly filled in one hour, it then stood full and quiescent for two hours, and was then slowly emptied in one hour. The beds were then allowed to stand quite empty for about three hours, hence every bed was filled and emptied three times every 24 hours, and on every seventh day the beds were left standing empty. Under this system, when the rate of filtration was about 1,000,000 gallons per day per acre of filter surface, a purification of from 75 to 83 per cent. was obtained; it was found that the filter remained free of putrescent matter, and when standing empty, the only smell was that of fresh garden mould. In the early experiments the sewage distributed to the filters had already undergone chemical treatment, but as a result of his experiments, Dr Dibdin recommended that the chemical treatment should be omitted, that grosser particles should be screened out, and that, thereafter, the sewage should be passed through two sets of filter beds, the first set of beds, or coarse beds, to be filled with breeze of about $\frac{3}{4}$ -inch mesh, and the second set of beds, or fine beds, to be filled with breeze of a much finer mesh. In consequence of the successful results he obtained in these experiments, Dr Dibdin in 1896 advised the authorities of Sutton, who had constructed in 1890-93 sewage treatment works on the chemical system, using lime and proto-sulphate of iron with further treatment of the effluent from the settlement tanks on a sewage farm, to change over this system, which had failed to produce a satisfactory effluent, to the bacterial-bed method. The works were laid out with screens to intercept floating material, coarse and fine beds, and the method of working was precisely that evolved in the Barking experiments, the filling and emptying of the beds being entirely controlled by simple automatic devices; the results were quite satisfactory and the installation of this system at Sutton may be said to have been the beginning of the radical changes in the methods adopted in the purification both of domestic and of trade sewage, which have been such a marked feature of the schemes for sewage treatment designed and brought into use during the present century.

Quite early in the experimental researches on bacterial activities in sewage purification it was discovered that there were two distinct groups of such organisms, namely, those which carry on their work without the need of oxygen, called anaerobic organisms, and those which can most actively carry out their function in the presence of a plentiful supply of oxygen, aerobic organisms. There are, moreover, bacteria which are indifferent to the absence or presence of oxygen. The addition of chemicals to the sewage tends to hinder the work of these organisms, hence the advisability of abandoning the addition of any chemical if the bacterial treatment of sewage is to be successful. Most of the treatment works designed since these early experiments have adopted either the method of continuous application of the sewage to the beds, usually by some form of automatic sprinkler, or the method of filling the bed and allowing it to stand quiescent for a definite period before emptying, as employed by Dr Dibdin, commonly called the 'contact bed' system.

Another important addition to the plant employed was the use of the so-called septic tank, into which the sewage was run after passing through screens to separate off floating impurities and through detritus or grit chambers in which the gritty inorganic matter, largely the result of road washings,

settled out of the sewage. These septic tanks were constructed much on the same lines as the settlement tanks in the chemical treatment, and were either covered or open tanks, generally the latter. It is in these septic tanks that the main work of the anaerobic organisms is carried out, hence the idea that it was necessary to cover the tanks in order to exclude the air and light, but a thick heavy scum rapidly forms on the surface of the liquid, which effectually excludes all light and air from the great mass of the sewage; and if the entry of the sewage into the tank and the escape of the effluent are so arranged that both take place without disturbing this scum coating, no other cover of the tank is really necessary, except where, under exceptional climatic conditions, it may be necessary to protect the contents against the action of severe frosts. It is highly undesirable to allow the liquid to remain too long in the septic tanks—about twenty-four hours is the maximum time necessary for the strongest sewage, and with sewage diluted by rain-water this may be reduced to eight hours. The septic tank system was first used on a practical scale at Exeter, where a plant on this system was designed by Cameron in 1895.

While in all methods of sewage purification some system of 'screening' is essential, it plays a very little part in the purification process, nor do the detritus tanks, into which the sewage flows after passing through the screens, have much effect; the sewage is only allowed to remain long enough in the detritus tanks to secure the settlement of the gritty inorganic matter—that is, for a period of a few minutes up to a maximum of one hour, or long enough for about 10 to 25 per cent. of the suspended matter to settle out. Mechanical cleansing devices must be arranged both for the screens and for the detritus tanks. In many installations plain sedimentation tanks are employed instead of septic tanks, the sewage only remaining in such tanks about six hours, and the deposited sludge is removed at frequent intervals in order to prevent any very active bacterial action. The chief merit of the septic tank is the fact that the sludge it produces is drier, more easily handled, and has a less offensive smell than that produced by chemical treatment. In the Imhoff type of sedimentation tank, by making the tank a two-story one, the septic action is confined in great part to the sludge which settles in the lower chamber from the upper sedimentation chamber, the sewage flowing through this latter without disturbing the sludge in the lower chamber. In this tank provision is made for drawing off the sludge without hindering or influencing in any way the flow of the sewage through the tank, and by the device of separate gas-vents the gases produced by the decomposition of the sludge are drawn off, and may by suitable arrangements be utilised for the generation of power; about three-tenths of a cubic foot of gas is obtained per diem per head of population. The sludge from these tanks is easily dried, and is free from offensive odour. Where the contact-bed arrangement is adopted, the usual plan is to employ two sets of beds, the depth of the beds varying from 2 to 6 feet. In the first set, or primary beds, a coarse material, 2 or 3 inch mesh, is used, and in the second set, or secondary beds, a finer material of $\frac{1}{4}$ to 1 inch mesh; the material may be broken stone, clinker, coke, slag, &c. The efficiency of these contact-beds depends not so much on the depth as on the volume of the filtering material; in dealing with ordinary domestic sewage, about 1 acre of surface-beds is needed for 5000 persons if the beds are 5 feet deep. All contact-beds suffer a gradual reduction of air-space between the pieces of the filtering material, owing to the deposition of sus-

pended matter in the sewage and to other causes, hence after periods varying from two to twelve years they must be cleaned, the filtering material being removed and washed—this cleaning is required at shorter intervals of time in the case of the primary beds. The filling and emptying is controlled in large installations by hand, but in the case of smaller plants more usually these operations are automatically controlled by siphons.

Sprinkling filter-beds are, on the whole, more commonly employed than contact-beds; where the sewage is fairly free from suspended matter, the sprinkling is of the intermittent type, the sprinklers being rotary in the case of circular beds, or a rectilinear traveller in the case of beds rectangular in plan. Fig. 11 shows a circular bed with a sprinkler of the Candy type. Where there is much suspended matter, it is safer to use fixed pipe sprinklers, the pipes being fixed either above the top of the bed or near the bottom of the bed, the sewage, of course, in both cases being sprinkled over the surface of the bed.

The material used in the sprinkler-beds is similar in character to, and broken to about the same gauge as, that employed with contact-beds. The sprinkler-beds are from 6 to 8 feet in depth, and the rate of filtration for raw sewage varies from 200 to 250 gallons per square yard of surface per diem; this means about 1 acre of filter surface per 10,000 persons for a 5 foot deep filter. It is essential in these beds thoroughly to underdrain them in order to make good provision for the entry of air into and its escape from the bed; this is usually provided for by laying all over the bottom of the bed a series of half-tile drains.

The principle of purification of sewage by any system of filters—land, contact, or sprinkling—is the same. The material of the filter is coated with a gelatinous film of organic matter undergoing oxidation, and the organic matter in the sewage is absorbed by this stuff, with the result of a purified effluent. With percolating filters some of the partially oxidised matter passes away with the effluent; this matter, called 'humus,' should be allowed to settle out of the effluent in tanks before the effluent is finally discharged into a stream, since the humus is liable to secondary decomposition if it passed into a stream and settled on its bed.

During recent years there has been a tendency to make less use of anaerobic methods, and to develop more the aerobic action, and several systems of sewage purification have been developed for supplying large volumes of air to the raw sewage in the presence of an inoculating media, activated sludge; most of these systems are still to a certain extent in the experimental stage, but some of them have been designed on a big scale, as, for example, at Sheffield, where the Haworth bio-aeration process is now under construction for dealing with a daily dry-weather flow of 15,000,000 gallons of sewage containing a large proportion of trade waste liquor from the iron and steel industries.

In the diffused air system the sewage is first screened and passed through detritus tanks; it then passes into a circular disintegrating tank, where, by the diffusion of air through the liquid, all friable matter is broken into small particles; it then flows into a grease-collecting chamber, from this chamber the liquid, freed from grease, passes into a mixing chamber, where it is mixed

with a definite amount of activated sludge which has been aerated, the amount of this being determined by the nature of the effluent it is desired to produce. The mixture now passes into the aeration channels, in which the purification process is carried out; these channels are of considerable length, generally consisting of a number of channels side by side, the mixture passing slowly through all the channels in succession; all along these channels there are air-diffusers, through which air is blown into the liquid; to prevent any danger of the sewage not passing steadily along the channels, there are cross baffle walls in them with small openings in the walls just above the porous diffusers through which air passes into the liquid. The

Fig. 11—Sprinkling Filter.

diffused air keeps the sewage in constant agitation; it assists the coagulation process, and supplies the air for the active bacterial organisms. The air-pressure needed is from 5 to 10 lb. above the atmospheric pressure, the volume of air being at times as much as 10 cubic feet per square foot of tank area per hour. The sewage now purified passes to the settlement tanks, where the sludge is deposited, and the clear effluent drawn off from the surface of this tank can now pass to an outfall, no further purification being necessary. The sludge is continuously forced out of the settlement tank by the pressure of the liquid above it and passes into a channel where it is rendered still further active by diffusing more air in it, and from this channel it passes into the mixing chamber, where it mixes with a fresh supply of incoming raw sewage, any surplus sludge being withdrawn when necessary from this channel. This process produces more sludge than any of the ordinary septic tank methods, and one of the difficulties of this method is the disposal in an economical and satisfactory method of the large volume of sludge; in its favour is the fact that it produces a superior effluent and the system works without giving off troublesome bad odours. The air-diffusers are apt to clog up, and, though the plant needed is fairly simple in construction, the air-compressing plant cannot in the circumstances of the case be very efficient, owing to the fact that only a moderate air-pressure is needed to force the air through the porous walls of the diffusers.

In the bio-aeration and other similar processes the aeration and oxidation are brought about by the use of mechanical appliances. In the Sheffield scheme, after the preliminary action of screens and detritus tanks and also continuous flow settlement tanks, the sewage is compelled to traverse a long length of aeration tank, the time of travel being from 6 to 8 hours; the aeration tanks are 265 feet long by 4 feet 5 inches in depth, of rectangular cross-section, and are built up of a series of parallel channels placed side by side, connected at their ends, so that the sewage traverses a length of rather over a mile in its passage from the point of entry until it passes into the settling tanks at the end of the channels. In each channel a 10-foot

diameter paddle-wheel rotates at about 15 revolutions per minute; these are driven by an electric motor through suitable gearing; the wheels have a semi-circular cover, and by their rotation they set up short waves, which keep the sewage in a continual state of agitation. The settling tanks are of the well-known Dortmund type, of a pyramidal shape, each about 25 feet by 25 feet square at the top and 22 feet 6 inches deep. It is estimated that the power needed, including that required for pumping the sludge, will be from 20 to 25 h.p. for each million gallons of sewage dealt with. The power required is rather greater in this scheme, owing to the large volume of trade refuse which has to be dealt with, than it would be in a plant dealing only with domestic sewage. So far the results obtained have been quite satisfactory in regard to the effluent, and also in regard to the quality of the sludge produced.

There are several other systems adopting mechanical processes for the necessary agitation and aeration of the sewage; in the Simplex system, which has proved very satisfactory for dealing with trade waste, the tank used in the process has a conical bottom, and standing in the centre is a vertical pipe, open at its top and bottom, up which a stream of activated sludge and sewage passes and streams out on to a revolving cone fitted with suitable vanes; the mixture is flung off this revolving cone in a film, and this film striking the liquid in the upper part of the tank sets up such a disturbance in the mass that the liquid is thoroughly aerated and a spiral motion is set up in the tank. The tank is fitted with a thin inner shell-wall, which divides the tank into a large central compartment, in which the aeration occurs, and a narrow outer compartment, up which the liquid passes away to an overflow sill. Excess sludge is drawn off by a pipe which extends down almost to the bottom of the tank.

In conclusion, it may be pointed out that the solution of this difficult problem of sewage purification is not attained merely by the production of a stable, clear effluent not liable to after putrefaction, but must also secure the economical and satisfactory disposal of the resultant sludge.

Sewing-machine, a machine for sewing and stitching upon cloth, leather, and other materials. It has reduced the labour of family sewing to a minimum, created a new and profitable article of merchandise, to wit, 'ready-made clothing,' and revolutionised the manufacture of shoes.

There are many kinds of sewing-machine, each adapted to the kind of work it is intended to perform, as machines for general domestic or family purposes; for manufacturing purposes; for the vamping of shoes, stitching of water-hose, water-buckets, mail and travelling bags and satchels, and gloves; for carpets, buttons, button-holes, and for bookbinding.

Sewing-machines may be divided into classes, according to the stitch made, as the 'chain-stitch,' the 'double-loop stitch,' the 'lock-stitch,' and the 'button-hole stitch' machines.

The 'chain-stitch' machine uses but one thread, looped upon itself, by means of a curved needle or hook, beneath the cloth, which catches the thread as it is carried through the cloth in the eye of the vertical needle, and holds it until the second descent of the needle, this time through the loop thus made, which is drawn up upon the under side of the cloth as the vertical needle again rises, and so on—thus making a chain of stitches which is easily unravelled. Machines of this class are of limited application,

Fig. 1.

being better adapted for embroidering and basting than for manufacturing purposes or for general domestic use. Fig. 1 represents this stitch.

The 'double-loop stitch' is a machine using two threads, one upon each side of the fabric—the upper thread in the eye of the vertical needle above the cloth, the other in the circular needle which vibrates immediately beneath the cloth. By the descent of the vertical needle the upper thread is carried down through the cloth, where it becomes looped and interlooped with the under thread, forming a stitch which, being interlooped with the adjacent stitch, presents the appearance of three threads interlooped upon the under side of the cloth, and upon the upper side the single thread, as in the 'single chain-stitch.' This 'Grover and Baker stitch' makes a strong and durable seam, but consumes a large quantity of thread, and is easily unravelled.

The 'lock-stitch' class of machines, sometimes called the 'double lock-stitch' machines, comprises most of the machines now in use, and is admirably adapted for domestic and manufacturing purposes. Like the 'double-loop stitch,' the 'lock-stitch' machine is a double-threaded machine, having one thread upon either side of the fabric. The upper thread of the lock-stitch machine is carried by the descent of the needle bar downward through the cloth and the loop of the under thread, and by the upward motion of the needle is again brought back through the cloth, drawing the under thread upward to the centre of the fabric, where, by a proper adjustment of the tension of the two threads, they are locked, making a perfect stitch, exactly the same upon both sides of the cloth.

Fig. 2.

Fig. 2 represents the 'lock-stitch,' than which nothing better is required for sewing. By this stitch an elastic and durable seam is made, which even the skilled operator finds difficulty in ripping. It will not unravel. Of this class of machines there is also a large variety, which may be subdivided into two classes—those using the vibratory, oscillatory, or shuttle motions, and those constructed entirely upon the rotary motion principle, the loop being caught by the beak of the shuttle or by a rotating hook.

The button-hole machine makes the 'whip-stitch' of the button-hole and also the 'pearl-edge stitch.' It is a wonderful piece of mechanism.

Machines have been invented for taking the 'back-stitch,' the 'basting or running' stitch, the through-and-through stitch known as the 'cord-wainer's' stitch, the over-and-over stitch; indeed every stitch used in plain and fancy needlework except the 'blind' or 'hemming' stitch.

The hemming stitch must not be confounded with 'hem-stitching,' a well-known process by which certain threads of the 'filling' of cloth are drawn, and the warp artistically wrought into clusters or groups of threads by the use of the needle. The hem-stitching effect is produced upon the sewing-machine by the weaving of the thread alternately through the edges of adjacent pieces of cloth, then by the lock-stitch, sewing the threads through the centre, by stitches lengthened for the purpose of producing the effect desired. By a similar process, the skilled operator can readily produce lace in beautiful and artistic designs; and the effects of old tapestry may even be produced by the use of the sewing-machine.

History.—The idea of the sewing-machine originated in England during the 18th century, but as an invention of practical utility it is a product of the 19th century, and of the United States of America. In June of 1755 Charles F. Weisenthal patented a needle in England, having an eye in the centre, and being pointed at both ends. It was intended for hand embroidery, but was subsequently used in some of the earlier sewing-machines. Robert Alsop in 1770 patented in England a device for embroidering with one, two, or more shuttles. This was followed in 1804 by a machine, invented and patented by John Duncan, for embroidering, consisting of a large number of barbed or hooked needles set in a horizontal bar, and supplied with thread by a feeding needle. By a forward motion of this bar the needles were simultaneously carried through the fabric, and by the reverse motion were again brought back, passing through the loop of thread made by the previous stitch, thus making a 'loop-stitch.' This machine was subsequently improved by Mr Heilman, and extensively used for embroidery purposes.

Meanwhile, in 1790, a patent was taken out in England by Thomas Saint 'for quilting, stitching, and making shoes, boots, spatterdashes, clogs, and other articles.' This machine used a single thread, made a loop-stitch, the loops being upon the outer side of the fabric, had a perforated awl by which the hole for the needle was made, and was worked by a combination of 'cogs,' 'prongs,' 'wheels,' and 'spindles.'

In 1834 M. Thimonnier, a Frenchman, secured a patent in England for a crocheting-machine for sewing purposes, which made a loop-stitch by means of a hooked needle that had to be passed through the cloth backward and forward twice in order to make one perfect stitch. This machine improved was subsequently patented in France, and in 1851 in the United States. In 1871 Archbold and Newton secured a patent for sewing or stitching the

thread. In 1842 J. Greenough of Washington secured a patent in the United States for a machine for sewing shoes. This machine made the 'through-and-through' stitch, or 'shoemaker's stitch,' represented in fig. 3, using a single thread in the eye of Weisenthal's needle, *a*, the needle being drawn through backward and forward by means of pincers upon each side of the material. There was neither 'chain,' 'loop,' nor 'lock' by which the firmness and durability of the 'hand-sewed' shoe or of the ordinary 'back-stitch' for garments was secured, and hence this machine could not be adapted for general sewing. In 1843 B.W. Bean of New York patented a machine making the 'running' or 'basting' stitch, a stitch similar to the 'through-and-through' stitch, but by quite a different device (see figs. 3 and 4, and compare) and designed for a different class of fabric. Fig. 4 represents the device used in the machine for the making of the

Fig. 4.

running stitch. The needle, *a*, is long and stationary, with the eye and point at opposite ends, as in the ordinary needle for hand-sewing, and receiving a continuous supply of thread from the reel, *b*; the two small toothed wheels, *c*, are so arranged that their teeth pressing into one another crimp the two pieces of cloth, *d*, and push them forward against the needle-point, the operator drawing off the cloth from the needle at the eye end as rapidly as it is filled. This machine was extensively introduced into England, and used by bleachers, printers, and dyers for temporary basting, and for loose tacking of pieces of stuff.

The machine destined to revolutionise the sewing world and play a most important part in future industries was not yet conceived. The thought of the inventor had been centred apparently upon facilitating the embroidery of various articles of household and dress ornamentation, excepting the effort to lessen the labour of making shoes. Walter Hunt of New York is said to have constructed a machine for taking the lock-stitch in 1832 or 1834. However, to Elias Howe (1819-67), of Cambridge, Massachusetts, belongs the credit of constructing and patenting the first lock-stitch sewing-machine. Compared with the almost perfect machines of to-day, this machine was indeed a crude effort; it however formed the basis of the present lock-stitch sewing-machine, and comprised its essential features. It was patented in 1846, although possibly constructed earlier. Mr Howe combined a needle having the eye near the point vibrating in the direction of its length, though horizontally, with a shuttle device vibrating horizontally, yet so as to pass through the loop made by the thread in the needle eye being carried through the cloth, then drawn backward in the opposite direction; together with the 'sawmill carriage' 'feed motion,' and a baster-plate and projecting pins holding the cloth as in metal clamps in a vertical position while being stitched. The needle of the Howe machine was a great invention, without which no sewing-machine is possible; improvements were, however, soon made in the 'setting' of the needle, substituting the vertical motion of the needle for

Fig. 3.

backs of gloves, with the ornamental or tambour stitch, the tension being regulated by passing the thread over a roller covered with cloth, and by the alternate rising and falling of a bar across the

the horizontal motion of the original machine, thus passing the cloth upon the table of the machine horizontally under the needle, together with a 'wheel feed motion' beneath the baster-plate, by which the cloth was moved horizontally from left to right. Subsequently the shuttle was made to describe an entire circuit instead of the former oscillating or vibrating motion. This latter improvement was made and patented by Blodgett and Heron of Boston in 1849; but while it effectively economised power, it was soon found impractical because of the untwisting of the thread as the shuttle rotated. In 1850 Allen B. Wilson of Pittsfield patented a 'double-beak shuttle,' by which a complete stitch was made at each forward and backward motion of the shuttle, which also economised power. About the same time Robinson of Boston patented a machine having two needles curved, which being threaded with short threads, one upon each side of the cloth, were passed alternately through the cloth, and the thread drawn each way, making the cordwainer's stitch. By this machine the back stitch and the basting stitch could be made.

In 1851 Mr Wilson invented and patented the 'rotating hook' device, a device new in machinery and an effective substitute for the shuttle. Mr Wilson also made a most substantial improvement in his lock-stitch rotary motion machine, known as the 'four-motioned feed' or 'rough surface feed with yielding pressure.' It consists of a horizontal slotted bar placed between the standards which support the cloth plate, with a 'feed-tongue,' which fills the slot, and is pivoted at one end, but free at the other end for an up-and-down motion. The four motions are an upward or lifting motion by which the teeth are fixed in the cloth, a forward motion by which the cloth is moved forward, a downward motion by which the teeth loose their hold upon the cloth, and a backward motion effected by a spiral spring at the other extremity of the feed-bar. The length of the stitch is determined by the play of the feed-bar. By the successive motions of this rough surface feed, the only hold upon the cloth while the needle is passing down through the cloth is the needle itself; hence the cloth may be turned in any direction by the operator without stopping the machine, an advantage which will be readily appreciated, making it possible to turn corners while sewing. In 1849 a 'chain-stitch' machine was patented by Morey and Johnson, in which the cloth was suspended from a circular baster-plate, the thread being carried through the cloth by the horizontal play of the needle. This machine was subsequently improved by J. E. A. Gibbs of Virginia, and as improved is known as the Wilcox & Gibbs machine. The double loop-stitch machine before described was invented and patented by W. C. Grover and W. E. Baker of Boston in 1852. Immediately after the Singer machine, bearing the name of the inventor, was patented. It was an improvement upon the original Howe machine, and it in turn has been improved from time to time with various patents. In 1856 Chapin secured a patent for the 'hemmer,' a device of steel consisting of a 'scroll' or 'gauge' set in a steel 'presser-foot,' by which the hem or fell is turned. It is an attachment adapted to any sewing-machine. Various patents have been secured for the various attachments and improvements from time to time, and also for new machines adapted to special classes of work. The button-hole machine was invented and patented in 1882 by Ostrom, and almost at once materially improved by Horace Doggett, a young man under twenty, by the addition of an 'automatic cutter.' This device was subsequently purchased by the Wheeler and

Wilson Company. Attachments for the working of button-holes were adapted for use upon any sewing-machine, and there are various kinds of button sewing-machines.

Immediately after the invention of the Singer machine litigation arose between the various inventors, and terminated in 1854 in a sewing-machine combination, by which all companies united in the use of the Howe needle and the Wilson four-motioned feed, paying their inventors a royalty. The last of the important original patents ran out in 1878, and immediately sewing-machines were reduced in price fifty per cent. Since then there have been many improvements, but the principles remain.

Sex. In all the many-celled animals, and in most of the many-celled plants, the continuance of life from generation to generation is secured by special reproductive cells which form new lives, being sooner or later separated from the body of the parent. In this specialisation of reproductive cells lies the great difference between sexual and asexual reproduction. But in the great majority of organisms the special reproductive cells are of two kinds—there are relatively large and passive ova, and relatively small and often very active spermatozoa. These two kinds of reproductive cells are mutually dependent; in most cases they die unless they unite with one another. When this union or fertilisation takes place a new life begins. But in most organisms the ova are formed in one organ, the spermatozoa in another, while in most animals, and in all the higher forms, the ova are formed by one individual (a female) and the spermatozoa by another (the male)—there being, in other words, two distinct sexes. Moreover, the males and females differ not only in their essential characteristics of producing spermatozoa and ova respectively, but they often differ very markedly in external appearance, constitution, and habits. Further, they are instinctively attracted to one another in such a way that the union of the complementary reproductive cells is secured.

It is evident then that the fact of sexual reproduction involves many distinct biological problems: (a) the formation of specialised reproductive cells; (b) the origin of two different kinds of reproductive cells—ova and spermatozoa; (c) the differentiation of distinct organs or of two distinct types of individual for the production of these two kinds of elements; (d) the divergence between the sexes in secondary as well as in essential characteristics; and (e) the evolution of the sexual instincts which find their highest expression in the love and courtship of many of the higher animals. As the general problem of sexual reproduction is discussed in the article REPRODUCTION, and as the divergent modes of sexual reproduction are discussed in special articles, such as HERMAPHRODITISM and GENERATIONS (ALTERNATION OF), we shall confine ourselves here to the problems immediately connected with the evolution of sex.

What is the meaning of the existence of two distinct sexes? The problem may be approached in several different ways. We may, for instance, inquire whether this normal divergence of individuals into two types has any analogue among other cases of divergent variation among organisms. To some the analogy seems not far to seek. For throughout organic nature a great contrast may be read, between plant and animal, Gregarine and Infusorian, coral and jellyfish, barnacle and shrimp, coccus-insect and fly, slug and Pteropod, tortoise and lizard, reptile and bird, and even more clearly between related genera or even related species; a contrast between predominant passivity and activity, between a storing and constructive physiological habit and one which is prone to expen-

diture and disruption; a contrast expressible in technical language as an antithesis between a relative anabolic and a relative katabolic preponderance in the protoplasmic life of the creature. Now it may be that the difference between the sexes, between the relatively passive female and the more energetic male, is an expression of what is really a fundamental alternative in variation.

Or we may take a survey of the contrasts between the sexes, and endeavour, after making allowance for the special conditions of each case, to reach some average truth. Then we find that females tend to be larger, more sluggish, less brightly coloured and decorative, that they often have a longer life and sometimes a higher temperature; and that males, on the other hand, tend to be smaller, more energetic, more brightly coloured and decorative, and so on. Now, these characteristics, when physiologically analysed, tend to corroborate the theory that the females and males are individuals of relatively anabolic and relatively katabolic constitutions.

Again, we may approach the problem by inquiring into the physiological conditions which tend in each birth to determine whether the individual will be a male or a female. While the progress of research is confirming the view that in the higher animals at least the sex of the future offspring is irreversibly predetermined at a very early stage in the history of the germ-cells, there are some interesting facts which go to show that the nutritive and other environmental conditions of the parents may influence the proportions of male-producing and female-producing germ-cells. Thus markedly anabolic conditions favour the production and survival of female-producing ova, and conversely. There is no doubt that changes of nutrition may make various normally hermaphrodite organisms, such as hydra, into pure males or pure females. Or again, we may fix our attention on the characteristic products of the sexes—on the ova and spermatozoa. Here the difference between female and male has its fundamental and most concentrated expression. For the ova are relatively large cells, very passive, and usually rich in reserve-products, while the spermatozoa are very minute cells, usually very active, rarely with any reserve-products. In short, the ova (like the females) are relatively anabolic, and the spermatozoa (like the males) are relatively katabolic.

Recent researches have emphasised the importance of hormones produced by endocrinal tissue in the reproductive organs. These sex-hormones, distributed throughout the body by the blood, serve to activate the development of secondary sex-characters, or to inhibit the development of those of the opposite sex. They also have a profound influence on the nervous system.

We should also inquire into the beginnings of sexual differentiation among the simpler forms of life. Among the unicellular Protozoa, in which sexual reproduction in the strict sense cannot occur, there are already the analogues of males and females, as we see for instance in *Vorticella*, when a small free-swimming individual unites with a stalked cell of normal size. Very gradual among the simple plants also are the steps of sexual differentiation. But of especial importance is the genus *Volvox*—a colony of loosely united cells—in many ways related to the Flagellate Infusorians. In this globular colony division of labour is at a minimum, and individuals often occur which are quite asexual, forming daughter-colonies, without specialised reproductive cells. Others have, among the other units of the colony, special reproductive cells, which are, however, parthenogenetic, able of themselves to form new colonies. Others have special reproductive cells—ova and spermatozoa—formed within

the same colony, but usually maturing at different times. Then there are colonies in which only ova are formed, and others in which only spermatozoa are formed, cross fertilisation taking place as usual. And besides these various sexual conditions other combinations often occur in the same species of *Volvox*, in which we can indeed read, and with increasing physiological knowledge will more fully understand, almost the whole story of the evolution of sex.

Finally, it must be observed that the origin of two kinds of reproductive cells which combine in fertilisation, and the specialisation of two types of individual as the bearers of ova and spermatozoa respectively, must have been of advantage in the general evolution of organisms. For, as almost every life begins in the mingling of two distinct reproductive units produced by two distinct types of individual, there is here one of the most important sources of variation and one of the most important means of securing the average stability of the species.

But we must also recognise the psychical expression of sex—the love of mates. This also has its history. Among crustaceans and insects first, in fishes and amphibians, in reptiles too, but most markedly among birds and mammals, the males are attracted to the females, and enter into relations of helpfulness with them. The relations and attractions may be crude enough to begin with, but to mere physical fondness are added subtler attractions of sight and hearing, and these are sublimed in birds and mammals to what we call love. This love of mates broadens out; it laps the family in its folds; it diffuses itself as a saturating influence through the societies of animals and of men.

Cunningham, *Sexual Dimorphism* (1909); Marshall, *Physiology of Reproduction* (1910); Julian Huxley, *Essays of a Biologist* (1923).

Sexagesima Sunday (Lat. *sexagesima*, 'sixtieth'). See QUINQUAGESIMA.

Sextant, an instrument for measuring the angular distance of objects by means of reflection. The principle of its construction depends upon the theorem that, *if a ray of light suffer double reflection, the angle between the original ray and its direction after the second reflection is double of the angle made by the reflecting surfaces*. Thus, let A and B (fig. 1) be two mirrors perpendicular to the same plane, and inclined to each other, and let SA be a ray of light, which falling upon A is reflected on B, and re-reflected in the direction BC, then ACB is the angle between the original and finally reflected rays, and ADB is the angle between the mirrors. Now, as the angle of reflection is equal to the angle of incidence, $\angle SAF = \angle BAD$, and $\angle GBA = \angle DBC$; but $\angle EBC = \angle BAC + \angle BCA = (\angle BAD + \angle DAC) + \angle BCA = (\angle BAD + \angle SAF) + \angle BCA = 2 \angle BAD + \angle BCA$; and $\angle EBC$ also $= \angle EBD + \angle DBC = \angle EBD + \angle GBA = 2 \angle EBD = 2 \angle BAD + 2 \angle BDA$; therefore $\angle BCA = 2 \angle BDA$, which proves the truth of the theorem. The instrument of which this theorem is the principle is a brass sector of a circle in outline; the sector being the sixth part of a complete circle, for which reason the instrument is called a *sextant*. Fig. 2 shows the essentials of its construction; AMN is the sector whose curved side, MIN, is the sixth part of a circle; A is one mirror wholly silvered, placed perpendicular to the plane of the sector, and on, and in line with, the limb AI, which is movable round a joint at or near A; B is the other mirror, also perpendicular to the

plane of the instrument, and silvered on the lower half only, the upper half being transparent; E is an eyelet-hole or small telescope. The graduation runs from N to M (on a slip of silver, platinum, or gold let into the rim), and is so adjusted that, when the movable limb is drawn towards N till the mirrors A and B are parallel, the index which is carried at the foot of the movable limb is opposite zero on the graduation. If we suppose that this zero-point is at N, it is evident that the angle between the mirrors is equal to the angle NAI; and again, if instead of graduating from 0° at N to 60° at M, which is the proper graduation for the sixth part of a circle, the graduation be made from 0°

Fig. 1.

to 120°—i.e. each half-degree being marked as a degree, and similarly of its aliquot parts—then the angle NAI, read off by the index at I, will show at once the angle between the incident and finally reflected rays. The mode of using the sextant consists in placing the eye to the telescope or eyelet-hole, and observing one object directly through the unsilvered part of B, and then moving the index till the image of the other object, reflected from A upon the silvered part of B, coincides with or is opposite to the first object; then the angle, read off at I, gives the angle between the objects. For additional accuracy a vernier is attached to the foot of the movable limb.

Fig. 2.

The sextant is capable of very general application, but its chief use is on board ship to observe the altitude of the sun, the lunar distances, &c., in order to determine the latitude and longitude. For this purpose it is necessary to have stained glasses interposed between the mirrors A and B, to reduce the sun's brightness. These glasses (generally three in number) are hinged on the side AM, so that they may be interposed or not at pleasure. B is the glass through which the horizon is perceived, and has hence received the name of the *horizon-glass*; while the other mirror, from its being attached to the index-limb, is called the *index-glass*.

The sextant is liable to three chief errors of adjustment: 1° if the index-glass be not perpendicular to the plane of the instrument; 2° if the horizon-glass be not perpendicular to the plane of the instrument; and 3° if, when the mirrors are parallel (which is the case when a very distant body, such as the sun or moon, is observed directly through B, and found to coincide with its image in the lower part of B), the index does not point accurately to 0°; this last is called the *index-error*, and is either allowed for, or is remedied by means of a screw, which moves the index in the limb AI, the latter being stationary. The first two errors are also frequently remedied by means of screws working against a spring, but in the best instruments the maker himself fixes the glasses in their proper position.—The *quadrant* differs from the sextant only in having its arc the fourth part of a circle, and being consequently graduated from 0° to 180°; the *octant* contains 45°, and is graduated from 0° to 90°; while the *repeating-circle*, which is a complete circle, is graduated from 0° to 720°. A common form of the sextant is the 'snuff-box' sextant, which is circular in shape, and, as it can be conveniently carried in the pocket, is the form most frequently used by land-surveyors.

The idea of a reflecting instrument, on the principle of the sextant, was first given by Hooke about 1666; but the first instrument deserving the name was invented by John Hadley (q.v.) early in the summer of 1730, and a second, and much improved form of it, was made by him a short time afterwards. Halley, at a meeting of the Royal Society, claimed for Newton the priority of invention, and in October 1730 a Philadelphian, named Godfrey, also asserted his claim as the original inventor; but that learned body decided that Newton's claim was unsupported by even probable evidence, and that Hadley's and Godfrey's inventions were both original, but that the second form (which is almost the same as the common sextant now employed) of Hadley's instrument was far superior to his first form and to Godfrey's. See works by H. W. Clarke (1885) and C. W. Thompson (1887).

Sexton (corrupted from *Sacristan*, q.v.) is a parochial officer in England, whose duty is to take care of the things belonging to divine worship. He is usually chosen by the inhabitants, but often also by the clergyman or the churchwardens, the mode of appointment being regulated by the custom of each parish. He sometimes also holds the office of parish-clerk. Women have occasionally been appointed sextons (e.g. at Kingston-upon-Thames, 1731; Donnybrook, near Dublin, 1845-56; and the adjoining parish of Booterstown, 1856-74). The office is a freehold office for life, except in the new parishes under Church-building Acts; the duty is to keep the church clean, swept, and adorned, to open the pews, to make and fill up the graves, and to prevent any disturbance in church. The salary is usually paid by the churchwardens, and as to amount depends on custom. In Scotland he may also be beadle or 'church-officer,' although the latter's duties are usually connected with attendance on the minister.

Sextus Empiricus, physician and philosopher, lived at Alexandria and Athens about 200-250 A.D. As physician he was a representative of the Empirics (hence his second name; see *MEDICINE*); as philosopher he was the chief exponent of the later Scepticism (q.v.) of the Old World, which was professedly a continuation of Pyrrhonism. In his two works still extant—the *Hypotyposes* and *Adversus Mathematicos*—he has left a prodigious battery of arguments and exceptions against dogmatism in grammar, rhetoric, geo-

metry, arithmetic, music, astrology, logic, physics, ethics. There are monographs by Joudain (Paris, 1858) and Pappenheim (Berlin, 1875).

Sexual Selection is a term applied by Darwin to the process of favouring and eliminating which to some extent occurs in the mating of many animals. It is a special case of natural selection, depending upon a competition between rival males, in which a premium is set upon those qualities which favour their possessors in securing mates. This competition takes two forms: on the one hand, rival males, for instance stags and gamecocks, fight with one another, and the conquerors have naturally the preference in mating; on the other hand, rival males sometimes seem to vie with one another in displaying their attractive qualities before their desired mates, who, according to Darwin, choose those that please them best.

Darwin gives the following summary of his theory: 'It has been shown that the largest number of vigorous offspring will be reared from the pairing of the strongest and best-formed males, victorious in contests over other males, with the most vigorous and best-nourished females, which are the first to breed in the spring. If such females select the more attractive and, at the same time, vigorous males, they will rear a larger number of offspring than the retarded females, which must pair with the less vigorous and less attractive males. So it will be if the more vigorous males select the more attractive and, at the same time, healthy and vigorous females; and this will especially hold good if the male defends the female, and aids in providing food for the young. The advantage thus gained by the more vigorous pairs in rearing a larger number of offspring has apparently sufficed to render sexual selection efficient.'

Where there is direct competition between males, the weakest will tend to be eliminated, either directly by death or injury in the struggle, or indirectly by diminished success in reproduction. In the same way, if a male be lacking in the qualities necessary to find a mate—e.g. in senses acute enough to find out her whereabouts—that male may remain unproductive. But there is not enough of evidence to enable us to compute how many males do remain unmated in consequence of non-success in competition.

In regard to the second aspect of sexual selection, in which the females are believed to exercise some choice, giving the preference to those suitors which have brighter colours, more graceful forms, sweeter voices, or greater charms of some kind, there is no little difference of opinion. Darwin indeed believed strongly in the female's choice, and referred to this process of selection many of the qualities which distinguish male animals. The females 'have by a long selection of the more attractive males added to their beauty or other attractive qualities.' 'If any man can in a short time give elegant carriage and beauty to his bantams, according to his standard of beauty, I can see no reason to doubt that female birds, by selecting during thousands of generations the most melodious or beautiful males, according to their standard of beauty, might produce a marked effect.' On the other hand, Alfred Russel Wallace maintains a very different position. 'There is,' he says, 'a total absence of any evidence that the females admire or even notice the display of the males. Among butterflies there is literally not one particle of evidence that the female is influenced by colour or even that she has any power of choice, while there is much direct evidence to the contrary.' Against this, G. W. and E. G. Peckham, in their careful essay on sexual selection in spiders, state that they have in the *Attidæ* 'conclusive evidence that the females pay close attention to the love dances of the males, and

also that they have not only the power, but the will, to exercise a choice among the suitors for their favour.' Some observers of birds are also confident that the females choose the more musical or otherwise attractive males. But again Wallace maintains that the fact that every male bird finds a mate 'would almost or quite neutralise any effect of sexual selection of colour or ornament; since the less highly coloured birds would be at no disadvantage as regards leaving healthy offspring.' In spiders, however, it seems that the more brilliant males may be selected again and again while the mating season lasts.

The theory of sexual selection is of considerable importance in a general theory of evolution. This may be illustrated in reference to the bright plumage of many birds. If we postulate successive crops of variations (which cannot at present be completely rationalised), if we acknowledge that there is really 'preferential mating' among birds (which is not readily proved or disproved), if we believe that the females are sensitive to the slight excellences which distinguish one suitor from another and that their choice of mates is determined by these excellences (which Wallace emphatically denies), then we may say that the greater brightness of male birds may have been evolved by sexual selection. This was Darwin's opinion. The brighter males succeeded better than their rivals in the art of courtship; the variations which gave them success were transmitted to the offspring; gradually the qualities were established and enhanced as secondary sexual characters of the species. But Wallace interpreted the facts quite otherwise. The relatively plain plumage of the female birds was due to natural selection, eliminating those whose conspicuousness during incubation was fatal, fostering those whose colouring was protective. Just as Daines Barrington, a naturalist still remembered as the correspondent of Gilbert White, suggested (1773) that singing-birds were small and hen-birds mute for safety's sake, so Wallace maintained that female birds had forfeited brightness as a ransom for life.

But, leaving the birds, let us take a case which seems to afford better illustration of Darwin's theory of sexual selection—that of spiders. The courtship of these animals has been observed and described by G. W. and E. G. Peckham in a manner so careful that their paper ranks as one of the most important contributions yet made to the theory of sexual selection. 'The fact that in the *Attidæ* the males vie with each other in making an elaborate display, not only of their grace and agility but also of their beauty, before the females, and that the females, after attentively watching the dances and tournaments which have been executed for their gratification, select for their mates the males that they find most pleasing, points strongly to the conclusion that the great differences in colour and in ornament between the males and females of these spiders are the result of sexual selection.' It may be that the American observers have, especially in their psychological language, mingled a little imagination with their induction, but they state a strong case for sexual selection.

The conclusions drawn from the courtship of spiders are not affected by Wallace's criticism so seriously as are those which Darwin drew from the courtship of birds, and this suggests that the wisest position is one of compromise, which recognises that in some cases—e.g. spiders—the external divergence of the sexes may depend upon sexual selection, and that in other cases—e.g. birds—it may depend rather upon natural selection.

But even with this compromise it is difficult to rest satisfied. For before we can believe that attractively bright ornaments could become char-

was quietly swallowed up by Austria. The Dukes of Sforza-Cesarini descend from collateral branches of the family. See Magenta, *Gli Visconti e gli Sforza* (Milan, 1883).

Sgambati, GIOVANNI (1841-1914), Italian pianist and composer, was born in Rome (his mother being British), began the study of music at an early age, and became a protégé of Liszt. He was one of the founders of the *Liceo Musicale* at Rome in 1877, made many brilliant European tours as pianist, but latterly confined himself to teaching in Rome. Sgambati was remarkable for his refusal to bow down to the national operatic tradition, and for his championship of classical instrumental music. His compositions include two symphonies, a requiem, and chamber and piano music.

Sgraffito, or SCRATCHED WORK, is the name given to a mode of external wall-decoration practised in Italy, of which examples have been found in Pozzuoli near Naples, of the date of about 200 B.C. The process is accomplished by means of superimposed layers of plaster applied and operated upon in the following manner. First, the wall having been thoroughly moistened to ensure adhesion, a $\frac{3}{4}$ -inch coat of plaster is floated on, and before it is perfectly dry a $\frac{1}{4}$ -inch skin of black, red, or any other coloured plaster that will not fade is applied; when this is set and while it is still wet, a finishing coat of white plaster is added. A full-sized drawing of the design that is to be realised is then transferred to this outer coating, and the outline cut through to the second coat with a sharp instrument, and made broad or narrow according to the effect desired, and where necessary these incisions are enforced by additional lines as shading. The process is an economical mode of obtaining effect, but like 'fresco' requires to be executed while the material is moist, and therefore no more should be prepared than can be immediately operated upon. Examples of the system are to be found in the choir boys' school of St Paul's Cathedral, the inner court of the Science Schools at South Kensington, some private residences, and the interiors of some churches in England. The application of this principle of decoration is not confined to plaster, but extends also to superimposed metals and to pottery. There are 15th-century specimens of sgraffito pottery in the South Kensington Museum. The examples of house-decoration in Italy are of the 15th, 16th, and 17th centuries.

Shabatatz. See ŠABAC.

Shackleton, SIR ERNEST HENRY, Antarctic explorer, was born 15th February 1874 at Kilkee, County Kildare, was educated at Dulwich College, and at sixteen went to sea. In 1901 he was a member of Scott's expedition. In 1904 he became secretary to the Scottish Geographical Society. His own first expedition of 1907-9 reached 88° 23' S. lat., and pointed the way for Scott's attainment of the pole; his second (1914-16) aimed at the crossing of the Antarctic Continent, but the *Endurance* had to be abandoned in the Weddell Sea. The crew succeeded in reaching Elephant Island, while Shackleton went to South Georgia, crossed its unexplored mountains (with two others), and after several failures brought off the Elephant Island party. He set off again for the Antarctic in 1921, but on 5th January 1922 died off South Georgia. Besides his own works, *The Heart of the Antarctic* (1909) and *South* (1919), see *Life* by H. R. Mill (1923); *Wild, Shackleton's Last Voyage* (1923); and the article POLAR EXPLORATION.

Shad, a name applied to various fishes in the same genus, *Clupea*, as the herring. To some British species the fishermen apply the name *King of the Herrings*, and very large herring sometimes

turn out to be shad, which may be distinguished by a characteristic notch at the extremity of the upper jaw. Shads are what is called 'anadromous,' that is to say, they go up rivers to spawn. The eggs are numerous, small, heavy, and non-adhesive; they lie free, not buried in the gravel like those of salmon. The Common Shad or Allis Shad (*Clupea alosa*) is found on the British coasts and in the

Common Shad (*Clupea alosa*).

lower part of some of the large rivers, more abundantly in the Severn than in any other British river. It attains a length of two or even three feet and a weight of from four to eight pounds. It has no teeth. There is a single black spot behind the gills. Its flesh is of good flavour. The Twaite Shad (*C. finta*) is more plentiful on the British coasts, and is the common shad of the Thames, but the foul state of the river has now made it of very rare occurrence above London. It is smaller than the Allis Shad, seldom exceeding 16 inches in length; there are small teeth in both jaws, and a row of dusky spots along each side of the body. The flesh is coarser and less esteemed than that of the Allis Shad, but much used for food wherever the fish is plentiful. This species spawns later in the year than the last, and in order to permit it to deposit its spawn its capture in the Thames is prohibited after the end of June. It abounds in many of the rivers of France and other parts of Europe. A species of shad (*Clupea sapidissima*), generally weighing about four or five pounds, but sometimes twelve pounds, is very abundant during some months of the year in some of the North American rivers, as the Hudson, Delaware, Susquehanna, and St Lawrence, and is now bred successfully and in immense numbers in the United States piscicultural establishments. See Regan, *Freshwater Fishes* (1911).

Shaddock (*Citrus decummanus*; see CITRUS), a tree which, like the other species of the same genus, is a native of the East Indies, and which has long been cultivated in the south of Europe. It is said to derive its English name from a Captain Shaddock, by whom it was introduced from China into the West Indies. It is readily distinguished from most of its congeners by its large leaves and broad-winged leaf-stalk; it has very large white flowers, and the fruit is also very large, sometimes weighing ten or even fourteen pounds, roundish, pale yellow; the rind thick, white and spongy within, bitter; the pulp greenish and watery, sub-acid, and subaromatic. It is a pleasant, cooling fruit, and much used for preserves. The tree is rather more tender than the orange, but with proper care is often made to produce fine fruit in orangeries in Britain. Finer and smaller than the Shaddock proper is the Pomelo (also called Pummelo, Pomelmoose, and Grape-fruit), a variety rather larger than an orange which has sometimes a grape-like taste. Both varieties are grown in Florida.

Shadows, as ordinarily understood, are the result of the interception of rays of light by opaque or semi-opaque substances. Close inspection of

any shadow cast by light from a source of finite size, say the sun or a candle-flame, shows that its margin is not clear cut. The size of the source being finite, there must exist certain regions from which the source of light appears to be only partially screened. In these regions the shadow is partial (a 'Penumbra'); whereas in regions from which the source of light is wholly screened by the intercepting substance, the shadow is complete. If the source of light had no appreciable breadth the penumbra would vanish, and the margin of the shadow would be approximately sharp and clear cut, were it not for Diffraction (q.v.). Again, other forms of radiant energy may be intercepted, and corresponding shadows cast. Take, for example, sound. To appreciate the existence of sound shadows we must ourselves get within the shadow, that is, we must set ourselves so that a large obstacle intervenes between us and the source of sound. In such circumstances the intensity of the sound becomes very much diminished. It does not become wholly absent, for, the wave-length of the waves of sound being relatively great, the waves spread by diffraction into the shadowed region, and sound can come round a corner, though with reduced intensity, in a way light, with its short wave-lengths, cannot do. Still, in order that we may hear sound most effectively, the source of sound should be in sight. In electrical radiations shadows also may exist, and may be made evident by suitable means. In the kathode-tube shadows may be cast by obstacles placed so as partially to intercept the stream of 'kathode rays' on their way to form a phosphorescent patch. One and the same substance will not necessarily cast a shadow under all kinds of radiation; it may be opaque to some, not opaque to others of these. A stone wall is opaque to light, but is not opaque to electrical radiations of the relatively great wave-lengths used in Wireless Telegraphy and Telephony (q.v.). Again, rock-salt and glass cast no very apparent light shadows; but with radiant heat glass casts a distinct shadow, while rock-salt casts little or none. See HEAT, and LIGHT; also ECLIPSES.

Shadwell, THOMAS, a dramatic writer of some note in his day, though now only remembered as the 'MacFlecknoe' of Dryden's satire, was born in 1642 in Norfolk. He was educated for the law, but not finding it a pursuit to his mind he deserted it, and after an interval of foreign travel betook himself seriously to literature. His first comedy of *The Sullen Lovers* (1668) had great success, and he continued from year to year to entertain the town with a succession of similar pieces, a complete edition of which was published in four volumes (1720). The immortality which these must have failed to achieve for him he was fated to attain in another way. With Dryden he seems at first to have been on terms of friendly intimacy, and indeed the great poet contributed the prologue to his *True Widow*; but when Dryden flung his *Absalom and Achiophel* and *The Medal* into the cause of the court Shadwell was rash enough to make a gross attack upon him in the *Medal of John Bayes*. Dryden heaped deathless ridicule upon his antagonist in the stinging satire of *MacFlecknoe* and as 'Og' in the second part of *Absalom and Achiophel*. Though his works, hasty and careless as they are, exhibit lively talent and considerable comic force, all that the reading world now knows of Shadwell is that 'Shadwell never deviates into sense.' It was some consolation in 1689 to succeed his enemy in the laureateship, which it became necessary for Dryden to resign. He did not survive long to enjoy it, however, as in 1692 he died—of an overdose of laudanum, it is said. See FLECKNOE.

Shafites, the name of one of the four principal sects of the Sunnites (q.v.), or 'orthodox' Muslims. Its name is received from its founder, Abu Abdallah Mohammed Ibn Idris, called Al-Shāfiʿī, from one of his ancestors who descended from Mohammed's grandfather, Abdul Muttalib.

Shaft. See COLUMN.

Shaftesbury (locally *Shaston*—as in *Jude the Obscure*), a very ancient municipal borough in Dorsetshire, 3 miles SSW. of Semley station and 22 WSW. of Salisbury. It stands on a narrow chalk ridge, and commands magnificent views over Dorset, Somerset, and Wilts. The *Caer Palladur* of the Britons, it was made by King Alfred the seat of a famous abbey of Benedictine nuns (880), whither Edward the Martyr's body was translated in 980, and where Cnut died, 1035. At the date of Domesday Shaftesbury had three mints and twelve churches, but four only remain—St Peter's (Norman) the most interesting. Till 1832 Shaftesbury returned two members, and then till 1885 one.

Shaftesbury, ANTHONY ASHLEY COOPER, EARL OF, was born on 22d July 1621, at Wimborne St Giles in Dorsetshire, the seat of his mother's father, Sir Anthony Ashley (1551-1628), a clerk of the Privy-council. He was the elder son of John Cooper of Rockborne in Hampshire, who next year was created a baronet. His mother died in 1628, his father in 1631; and though he ultimately came into over £6000 a year, his estate was then torn and rent from him by unjust kinsmen to the tune, he tells us, of £20,000. His boyhood was mostly spent at Cashiobury in Herts, Southwick in Hampshire, and Maddington in Wilts, till at sixteen, having had three tutors, he went up as a gentleman commoner to Exeter College, Oxford, where he 'not only obtained the good-will of the wiser and elder sort, but became the leader even of all the rough young men.' He left without a degree, and in February 1639 married Margaret, daughter of the Lord Keeper Coventry. She died, sore lamented by him, in 1649; and nine months later he married Lady Frances Cecil, the Earl of Exeter's sister, who also dying in 1654, in 1655 he married pious Margaret Spencer, the Earl of Sunderland's sister, who survived him till 1693. Only two sons were born to him, both by his second wife, and one of them died in childhood; but by all three marriages he largely strengthened his family connections.

Meanwhile in 1640 he had entered the Short Parliament for Tewkesbury, but he had not a seat in the Long. A royalist colonel (1643), after ten months' service he went over to the parliament, either from pique or from 'the dictates of a good conscience,' and for nine months more commanded their forces in Dorsetshire, then from 1645 to 1652 lived as a great country gentleman. In 1653 he entered Barebone's parliament, and was appointed one of Cromwell's council of state, but from 1655 he was in opposition, and in 1677 we find him claiming to have 'had the honour to have a principal hand in the Restoration.' He was one of the twelve commissioners sent to Breda to invite Charles II. home, and a carriage accident on the way thither caused him a lifelong internal abscess, which in 1686 secured him a lifelong friend in an Oxford student of medicine, afterwards the famous philosopher, John Locke.

For his services he was made a privy-councillor (1660), and next year Baron Ashley and Chancellor of the Exchequer. He served on the trial of the Regicides; proved a diligent minister; supported the war with Holland; and after Clarendon's fall (1667), in which he had no direct share, sided with Buckingham, with whom he formed one of the in-

famous Cabal, and like whom he was fooled as to the Catholic clauses in the secret treaty of Dover (1669-70). He seems to have opposed the 'stop of the exchequer' (1672), which yet he justified; that same year was made Earl of Shaftesbury and Lord Chancellor (he proved a most upright judge); but in 1673, suddenly espousing the popular Protestantism, supported the Test Bill, which broke up the Cabal.

On 9th October, the Great Seal being demanded of him, he uttered one of his memorable sayings, 'It is only laying down my gown, and putting on my sword;' and, the bribe and the dukedom rejected that were designed to purchase his submission, he ranged himself against Danby as a champion of toleration, but for Dissenters only, and figured thenceforth as a defender of national liberties, or rather, it may be, as an unscrupulous demagogue. He opposed Danby's non-resistance Test Bill (1675), and in February 1677, for his daring protest against a fifteen months' prorogation, was sent to the Tower, whence he was only released a year later on making a full submission. As early as 1674 he had feigned apprehensions of a popish massacre; and though the 'Popish Plot' was not of his forging, but Oates's, he it was that passed the base coin, using that two years' terror (1678-80) against his opponents with a ruthless dexterity that must stamp him for ever with infamy. Not even the Habeas Corpus Act (q.v.), long known as Shaftesbury's Act, is a set off against the judicial murder of Lord Stafford, his personal enemy. Still, for a while he seemed to have completely triumphed. The fall of his rival Danby was followed by his own appointment as president of Temple's new Privy-council of thirty members (April 1679), and James's dismissal to Holland by an attempt to exclude him from the succession, in favour, not of William and Mary, but of Shaftesbury's puppet, the bastard Monmouth. That monstrous proposal gave Charles II. his chance, and in October 'Little Sincerity' (as he had nicknamed Shaftesbury) received his congé; and Shaftesbury from that time onward was driven into extremest opposition, indicting James as a recusant (1680), and bringing armed followers to the Oxford parliament (1681). In the July of that year he was again sent to the Tower, on a charge this time of high-treason, and though the Middlesex Whig grand jury threw out the bill in November, and he was consequently released, arrest was again impending, with no such chance of escape. Monmouth and Russell hung back from the open rebellion to which he promised to furnish 'ten thousand brisk City boys,' and, after some weeks' hiding, he fled to Holland early in December 1682. 'Delenda est Carthago' he had quoted against the republic ten years before; 'Carthago nondum deleta' greeted him now when he landed. On 22d January 1683 the 'fiery spirit' passed away at Amsterdam, whence the 'pigmy body' was borne home for burial in the place that had given him birth.

Transcendently clever, eloquent, and winning, fairly void too of lust and venality when most men were lustful and venal, Shaftesbury yet stands condemned by the many talents committed to him. He, who might have done so much good, did so little but what was evil. Whether for or against monarchy, for or against republicanism, for or against France, for or against Holland, he was always for himself—self the dominant principle to which alone he was true. At least, if that count for praise, he was the author of party government, ever ready to make capital out of religious animosities, 'atrocities,' perjuries, forgeries, anything. After all that has been written, men seem in doubt still whether Shaftesbury was the 'pure,'

'high-minded,' and 'great statesman' that Mr Christie would make him, or, what Charles pronounced him, 'the wickedest dog in England.' ('I believe, Sir, I am, of a subject—one remembers his witty rejoinder.) Whether, again, was he a deist; and here again we have the well-known story, how one day he said to a friend, 'Men of sense are all of one religion.' 'And what religion is that?' a lady broke in; to whom, turning and bowing, he answered, 'That, madam, men of sense never tell.'

See Dryden's *Absalom and Achitophel* and *Medal* (1681); part iii. of Butler's *Hudibras* (1678); the hostile *History* of Burnet, who is the chief authority for Shaftesbury's 'dotage of astrology'; the able apologetic *Life* by W. D. Christie (2 vols. 1871); the shorter, less partial study by Mr H. D. Traill in the 'English Worthies' series (1886); the article by Mr Osmond Airy in vol. xii of the *Dictionary of National Biography* (1887); and other works cited at LOCKE and CHARLES II.

ANTHONY ASHLEY COOPER, third Earl of Shaftesbury, philosopher, was born at Exeter House, London, February 26, 1671, the grandson of the above, and son of that 'shapeless lump,' the second earl (1652-99), by Lady Dorothy Manners, daughter of the Earl of Rutland. Locke superintended his education at Clapham under a learned governess, Mistress Elizabeth Birch, who taught him to speak Greek and Latin fluently; three years at Winchester (1683-86) were not happy ones, for his schoolfellows visited on him the sins of his grandfather. With a tutor and two other lads he then travelled for three years more in Italy, Germany, and France, and on his return applied himself to study. A zealous Whig, he sat for Poole (1695-98), but ill-health compelled him to turn from politics to literature; and there is little to record in his life beyond two visits of a twelve-month each to Holland (1698-99, 1703-4), where he lived with the Quaker, Benjamin Furly, and formed friendships with Bayle and Le Clerc; his accession to the earldom (1699); his marriage (1709) to Miss Jane Ewer of Lee, for 'the satisfaction of his friends,' but to his own subsequent contentment; his removal to Naples (1711); and his death there on February 15 (4 o.s.), 1713.

His somewhat superfluous writings (Lamb hits off their style as 'genteel') were all, with a single exception, published after 1708, and were mostly collected as *Characteristics of Men, Manners, Opinions, Times* (3 vols. 1711; 2d enlarged ed. 1714) and *Second Characters* (ed. B. Rand, 1914). Here the 'moral realist' expounds his system, which Pope has immortalised in the *Essay on Man*, and which Hunt reduces to the three main contentions, that ridicule is the test of truth, that man possesses a moral sense, and that everything in the world is for the best. An opponent of Locke, and a disciple of the 'Cambridge Platonists,' Shaftesbury found a follower in Hutcheson (q.v.), the founder of the Scottish school of philosophy. Still, like most prophets, he has had least honour in his own country, for, while there he was more attacked as a deist than praised as a philosopher, on the Continent he has attracted the attention, and generally the admiring attention, of thinkers like Leibniz, Voltaire (who, however, ridicules his optimism in *Candide*), Lessing, Diderot, Mendelssohn, and Herder.

See Fowler's *Shaftesbury and Hutcheson* (1882), the *Life* by Rand (1900), J. M. Robertson's edition of the *Characteristics* (1900), Hunt's *Religious Thought in England* (new ed. 1884), Leslie Stephen's *English Thought in the Eighteenth Century* (1876), and monographs by Spicker (Freiburg, 1872) and Gizycki (Leip. 1875).

ANTHONY ASHLEY COOPER, seventh Earl of Shaftesbury, was born in London, 28th April 1801. From the early training of a faithful old servant,

María Millis, the future philanthropist received his earliest and deepest religious impressions. He went to Harrow in his twelfth year, and to Christ Church, Oxford, in 1819, and took a first-class in classics in 1822, his M.A. degree in 1832; and he was made D.C.L. in 1841. As Lord Ashley he represented Woodstock in parliament from 1826 to 1830; and joining the Conservatives, then led by Lord Liverpool and Canning, he formed a close friendship with the Duke of Wellington, under whom he obtained the post of Commissioner of the India Board of Control (1828). Under Peel he was made a Lord of the Admiralty in 1834. In 1830 he married Emily, daughter of the fifth Earl Cowper (so that he was thus a connection by marriage of Lord Palmerston); by her he had six sons and four daughters. He represented Dorchester (1830-31), Dorset (1833-46), and Bath from 1847 to 1851, when he succeeded his father as earl. Among his earliest efforts at philanthropic reform was the promotion of two bills for the Regulation of Lunatic Asylums and for the better Treatment of Lunatics (1845), which have been called the Magna Charta of the liberties of the insane. He acted as chairman of the Lunacy Commission from 1828 till his death, a period of fifty-seven years. He took much interest in the passing of an act (1840) to prevent the employment of boy chimney-sweeps. He worked unweariedly for fourteen years on behalf of a bill limiting the hours of labour of women and young persons to ten hours a day, but it was 1847 ere a Ten Hours' Bill was passed, when it so happened he was out of parliament. He would not join Sir R. Peel's administration in 1841, because that statesman refused to countenance the Ten Hours' Bill; but in 1846 he supported Peel in his proposal to repeal the Corn Laws, an action which cost him his seat for Dorsetshire. A speech in connection with his Mines and Collieries Bill (1842) was considered his greatest effort. In 1842 was passed an act for abolishing the apprenticeship in mines, and excluding women and boys under thirteen from working underground; a Printworks Act was passed in 1845; and he was chairman of the Commission of Inquiry which resulted in the passing of the Factory Acts Extension Act (1867) and the Workshop Regulation Act (1867; consolidated 1878). In 1843 he joined the Ragged School movement. Relinquishing society and all amusements, he gave the remainder of his life to other beneficent schemes, and his time and strength were exhausted by letters, interviews, chairmanships, and speeches. Peabody's scheme for bettering the house accommodation of industrial London sprang from Shaftesbury's efforts in the same direction. He was the adviser of Lord Palmerston in many important church appointments. Active and vigorous to the last, he died at Folkestone, 1st October 1885. Although not a great orator, he spoke with neatness, force, and precision. In religious matters he was an out-and-out evangelical, and strenuously opposed ritualism, rationalism, and socialism when divorced from Christianity.

See his *Speeches*, with introduction by himself (1868); Hodder's *Life and Work of the Earl of Shaftesbury* (3 vols. 1886); *Life* by J. L. and B. Hammond (1923) and the *Study* (from the Evangelical point of view) by J. Wesley Braddy (1926).

Shag. See CORMORANT.

Shagreen, a term applied to the skins of sharks, rays, and other fish included in the order Selachia, whether they are artificially prepared or not. These skins are furnished with a covering of small nodules or grains of dentine, which is of a hard nature and resists wear of the surface better than ordinary leather. In the shagreen used by

cabinet-makers for smoothing wood, the grains or papille are sharp pointed and closely set, but in the case of the skins of allied species these grains are comparatively flat and of different outlines. Such skins, when prepared like parchment, dyed and smoothed, present an attractive appearance, and are used for covering small caskets, boxes, cigar cases, spectacle cases, and similar articles. Shagreen was formerly a good deal employed for covering also watch cases, instrument cases, &c. The name shagreen (Persian *sāghri*, meaning the back of a beast of burden) is also, and perhaps was originally, applied to the skins or to portions of the skins of horses, asses, and other animals prepared by unhairing and scraping them. Each piece is then stretched on a frame, and while they are still moist the seeds of a species of *Chenopodium* are sprinkled on the surface and forced in by means of the feet or of a press. The skin is then left to dry, and when the seeds are beaten out it has a pitted appearance. It is next pared down with a knife nearly to the bottom of these depressions, after which it is macerated in water till the pits swell and give the skin a pimpled appearance resembling that of a shark. A steeping in a warm solution of soda and afterwards in brine completes the dressing, and it can then be dyed. The covers of old Persian manuscripts are made of this shagreen, which is also used for horse-trappings and shoes in the East. Wood has been embossed by a process somewhat similar to the way leather shagreen is made. See EMBOSING.

Shāh (Persian, 'king,' 'monarch,' 'prince'), the general title of the supreme ruler in Persia, Afghanistan, and other countries of southern and central Asia. The sovereign, however, may, and outside of Persia frequently does, decline the title, assuming in its place that of Khān (q.v.), an inferior and more common appellation. The same title can also be assumed by the shah's sons, and upon all the princes of the blood the cognomen Shāh-zāda ('king's son') is bestowed. The words *check*, *cheque*, *chess*, *exchequer*, are derivatives.—For Shahpur, see PERSIA; for Shah Shuja, see AFGHANISTAN.

Shahabad, a town of Ondh, 80 miles NW. of Lucknow by rail, with a pop. (1921) of 18,696—less than a third of what it was in the 16th century. In 1868 there was a savage riot here between Hindus and Mussulmans at the Moharram festival.

Shahjahanpur, a town of British India, in the United Provinces, stands 100 miles by rail NW. from Lucknow. It takes its name from Shah-Jehan, in whose reign it was founded in 1647. It was a hot-bed of rebellion during the Mutiny of 1857-58. Sugar is made and exported. Pop. (1921) 72,616.—The district has an area of 1726 sq. m. and a pop. (1921) of 839,115.

Shah-Jehan, the fifth of the Mogul emperors of Delhi, was during his father's reign employed in military expeditions against the Rajputs, the independent Mohammedan states of the Deccan, and the Afghan tribes around Kandahar. From 1623 he was in revolt against the Emperor Jahangir, his father, and was still unreconciled at the latter's death in 1627, when he was at once saluted as emperor by the nobles. The chief events of his reign were the war against the Deccan sovereigns, which resulted in the complete destruction of the kingdom of Ahmadnagar (1636), and the subjugation (1636) of those of Bijapur and Golconda; an indecisive contest against the Uzbeks of Balkh (1645-47); attempts to recover Kandahar from the Persians (1637, 1647-53), which, however, was finally lost; and a second successful war, conducted by his son Aurangzebe, against the Deccan princes (1655). But in 1658 the emperor fell

dangerously ill, and his sons commenced to dispute regarding the succession. Ultimately Shah-Jehan was taken prisoner by Aurungzebe, and confined in the citadel of Agra till his death, December 1666. This emperor administered strict justice, and was an able and capable ruler, and a clever financier. The magnificence of his court was unequalled; the splendid 'peacock throne' was constructed by his orders at a cost of nearly £7,000,000. Many magnificent public buildings executed under his direction remain as monuments of his greatness. Chief of these are the superb Taj Mahal, and the lovely 'pearl mosque' at Agra (q.v.), and the palace and great mosque at Delhi (q.v.).

Shah Nameh. See FIRDAUSI.

Shaikh-Othman. See ADEN.

Shairp, JOHN CAMPBELL, one of the Shairps of Houston, Linlithgowshire, was born 30th July 1819. He was educated at the Edinburgh Academy and Glasgow University, whence he went as Snell Exhibitioner to Oxford. There he gained the Newdigate prize for an English poem upon Charles XII., and graduated with second-class honours in 1844. From 1846 to 1857 he was a master at Rugby. From Rugby he went to St Andrews as deputy-professor of Latin. In 1861 he succeeded to the Latin chair, and in 1868, upon the death of Forbes, to the principalship of the United College. In 1877 he was appointed professor of Poetry at Oxford, and reappointed in 1892. He died 18th September 1895.

Shairp was an ideal Scotsman, but with a strong appreciation of English life and thought. His patriotism was almost phenomenal. A summer spent out of Scotland he considered wasted. He explored its loneliest spots and revelled in all its historical associations. The haunts of Jacobites and of Covenanters alike fascinated him, and there are few better companions in the Borderland and the Highlands than his sketches and poems.

His character and thought were moulded by home surroundings, by love of nature and of Wordsworth (his favourite author), by life at Oxford, and by Coleridge, Scott, Keble, Newman, and Erskine of Linlathen. He found the routine work of teaching somewhat irksome, but as a professor he was suggestive, stimulating, and sympathetic. Few have enjoyed the friendship and esteem of so many distinguished men. His prose is clear, simple, and vigorous; his poetry fresh and natural, with a true ring in lowland Scots.

His principal works are *Kilmahoe* (1864), *Studies in Poetry and Philosophy* (1868), *Culture and Religion* (1870), *The Poetic Interpretation of Nature* (1877), *Burns* (1879), *Aspects of Poetry* (1881), *Glen Dessaray* (1886), and *Sketches in History and Poetry* (1887). See Prof. Knight's *Principal Shairp and his Friends* (1888).

Shakers, the popular name first applied in derision to 'The United Society of Believers in Christ's Second Appearing,' a sect first heard of in England about 1750. The first leaders of this sect were James Wardley or Wardlaw, a tailor, and Jane, his wife, seceders from Quakerism, who had come under the influence of the 'French Prophets' (q.v.). Jane, especially, claimed to have special spiritual illumination, and to have 'received a call' to go forth and testify for the truth; she proclaimed that the end of all things was at hand, that Christ was coming to reign upon the earth, and that his second appearance would be in the form of a woman, as prefigured in the Psalms. She still adhered to many of the tenets of the Society of Friends, of which she and her husband were members, and preached against war, slavery, profane swearing, and the taking of the legal oath. Among her followers was one Ann Lee, an

uneducated girl of poor parentage, of a highly nervous organisation, a strong will, and ambitiously fond of power, who, professing to have received a spiritual baptism, with a command to go forth and preach this new gospel, began to preach in Toad Lane and the adjacent streets of Manchester. She acquired great power over her hearers, who believed in her as one filled with the Holy Ghost, and speaking with the voice of God. The preaching in the streets, accompanied with shouting, speaking of tongues, and other physical manifestations, excited much public hostility, in consequence of which James and Jane Wardlaw, Ann Lee, and her parents were fined and imprisoned in the Old Bailey Prison in Manchester upon a charge of obstructing the streets and violating the Sabbath. A professed experience of Ann Lee while in prison, in which the Lord Jesus appeared before her and became one with her in form and person, led her to be recognised by Jane Wardlaw and her followers as the female Christ—the Bride of the Lamb—in whose person Christ had come to reign upon the earth. She was henceforth styled 'Mother Ann,' and has since been recognised as the 'Head' of this new order. Her claim to be the female Christ excited only ridicule among her neighbours; hence another special revelation—that the foundations of Christ's kingdom were to be laid in America. In the following year, accompanied by her husband and five of the most prominent members of the society—four men and one woman—she emigrated to America, and settled at Niskayuna, 7 miles from Albany, New York, now Watervliet, distinguished as the parent Shaker settlement in America. Here, in their wilderness home, 'Mother Ann' established absolute community of property, the sacred duty of labour, and enforced upon her followers celibacy, which she had previously taught as becoming to 'Believers,' teaching them that no form of love could be allowed in the Redeemer's kingdom, and that men called into grace must live as the angels, with whom 'there is no marrying nor giving in marriage.' Her husband, Mr Stanley, a blacksmith, to whom she had been married in early life, and by whom she had had four children, all of whom had died in infancy, now left her; but believing herself the 'Bride of the Lamb,' she was not daunted either in purpose or faith.

Early in 1780 Joseph Meacham, a Baptist preacher, and Lucy Wright were sent from New Lebanon to Niskayuna, to seek new light as to the way of salvation. They had both been greatly exercised in the religious revival, accompanied by physical manifestations not understood by the clergy, which had occurred the previous year in Albany and adjacent districts, and now, satisfied that in this new order they had found the key to their religious experiences, became believers in Ann Lee. The first converts to Shakerism in America, they returned home and founded a Shaker settlement at New Lebanon which still exists. The denunciations of Ann Lee against war, and her refusal to take the colonial oath, caused her to be suspected as a British spy, and as such she was for several months imprisoned at Poughkeepsie. In the spring of 1781 she started upon a missionary tour throughout the colonies, which she continued until the autumn of 1783, making a goodly number of converts and laying the foundation of future Shaker settlements. In the autumn of 1784 she died at Watervliet, having previously made over the 'headship' of the society to Joseph Meacham and Lucy Wright as representatives of the dual rule of God, through the male and female Christ, conferring upon Lucy Wright the title of 'Mother Lucy.' Her death was a great shock to her followers, many

of whom believed that she was to live in the physical form for ever upon the earth among her people. Her successors, however, taught them that like the male Christ she had cast off her dress of flesh, and withdrawn from worldly sight, but still lived among her people, visible to eyes exalted by the gift of spiritual sight. So all the saints would remain after death near and be in 'union' with the visible body of Believers, becoming their spiritual teachers. This was accepted as a new and divine revelation, and still is a vital part of the Shaker religion. Under the ministrations of Joseph Meacham and Lucy Wright ten Shaker settlements were formed and an organisation of these settlements effected, bound together by a covenant, recognising the duality of God, the divine mission of Ann Lee as the female Christ, the sacred duty of celibacy, labour, and community of property, and appointing elders and deacons of both sexes for the government of their temporal and spiritual affairs. Joseph Meacham died in 1796, after which for twenty-five years, and until her death, 'Mother Lucy' ruled as the sole head of this new order, discontinuing the title of 'Mother' for the female head of the order at her death, and appointing a successor with the title of 'Elderess,' which title is still given to the female head of the church.

Economically the Shakers were prosperous, and their communistic property at the end of the 19th century was valued at about \$10,000,000. They have now almost disappeared. They are the oldest communistic order in the United States, and by their success demonstrate the possibility—for a time at least—of communistic life. They have two classes of members—the 'Probationers' and 'Covenantors'; the former practically adopt the Shaker doctrines, but retain control over their own property, or, if they have given it to the community, may at any time resume control of it without interest; the latter consecrate themselves and their property to the society, never to be reclaimed by them or their legal heirs. All full members have equal rights in the community, without regard to the property consecrated, only that it is their all. Each Shaker settlement is divided into families, each family consisting of brothers and sisters, who live in the same house, sit upon opposite sides of the same table, and are presided over by an elder and elderess, their temporalities being superintended by a deacon and deaconess. They take their meals in silence, are scrupulously neat, live well but simply, employ no doctors, take no drugs, and are noted for their good gardens, flower-seeds, and medicinal herbs which they cultivate for the market. Their numbers are recruited mostly by young men and women, although occasionally married people with their children join the order. Believing that education is the right of all, they provide liberally for the education of the children left in their care. Their worship consists of vocal and instrumental music, 'dancing and making merry' followed by silent communion, and sermons which in point of devoutness, logic, and rhetorical form may fairly be compared with the sermons of the ordinary Christian churches. Their societies are united in one organisation presided over by the head elderess, assisted by the chief elder. They repudiate a priesthood, monarchy, and paid ministry, and teach that it is not Christ or Ann Lee, but the principles of Christ which must be accepted, and that all may become Christ's by death of the generative nature and an infusion of the Christ spirit. They repudiate the atonement by blood and the resurrection of the body as 'a horrid idea,' anti-Christian and anti-scientific. They have no creed, but depend upon divine revelation, which they claim is progressive according to the needs and

development of humanity. They believe that God is dual—the Eternal Father and the Eternal Mother—the heavenly parents of all beings angelic and human: that the first revelation of God to humanity was as a Great Spirit pervading all things, hence pantheistic worship; that the second revelation of God was as Jehovah; the third through Jesus, a divinely inspired man, representing God as a father; and that in 1770, the beginning of the last cycle, God was revealed in the character of the Eternal Mother—the bearing spirit of all the creation of God in divine love and tenderness—in the person of Ann Lee as the female Christ. Salvation, they teach, can only come by the death of the Adamic or generative life, by which man becomes a new order of being, able to comprehend 'the mysteries of God.' The earthly procreative relation for the purposes of reproduction is fit only for the children of this world, and carnal sexual indulgence is denounced as 'the unfruitful works of darkness.' Labour is 'a sacred and priestly duty,' and the work of the saints is by loving labour bestowed upon the earth to redeem it from the Adamic curse, which was lifted by the coming of Christ; each child born has a title-deed from God for land sufficient for its existence, and in the present advanced stage of civilisation this right is best recognised by a community of interest in the rent obtained for advantages of location, fertility, and mineral wealth. They denounce war, claiming that all disputes of individuals and nations should be settled by arbitration. They oppose the union of church and state, take no interest in governments as now constituted, loving their own country only as the favoured land of God, believing that in America the millennium is first to come when human governments, civil and ecclesiastical, will recognise the female element in harmony with the dual government of God. They make no effort to secure converts, it being a part of their religion that God will designate whom he has called to live in 'union,' and claim that instead of Shakers becoming extinct as is prophesied, and as they admit is prophetically indicated by their loss of membership, 'the first heavens and earth are passing away, and that a new heavens and new earth will be evolved out of the chaotic elements which exist in church and state humanity by the inspiration of revelation from the Christ heavens'—in other words, that the general principles of Shakerism will be established throughout the world.

ENGLISH SHAKERS was the name commonly given to a community calling themselves 'Children of God,' founded by Mary Anne Girling (born 1827), who about 1864 came to believe that she was a new and final incarnation of God, and insisting on celibacy. Founded in London, the communion grew to about 150 members, and in 1872 settled on a property purchased for them, New Forest Lodge, in the New Forest, Hampshire. Though industrious and blameless, they sank into poverty; and, unable to pay their debts, were evicted in December 1873, and subsequently, shrunk to twenty or thirty in number, lived a miserable existence in sheds and temporary shelters. Mrs Girling, who was confident she would never die, did die of cancer, 18th September 1886, and her sect collapsed.

See Elder F. W. Evans, *The Shakers* (New York, 1859), his *Autobiography of a Shaker* (1879), the Shaker magazine; also Eads, *Shaker Sermons* (1879).

Shakespeare, WILLIAM (1564–1616), dramatist, poet, and actor, was born at Stratford-on-Avon in April 1564. The details of his early life are somewhat meagre. This is not surprising, for in the 17th century there was little of that curiosity in the author's private life which plays so important a part in modern criticism. No attempt was made to write a life of Shakespeare

until at least two generations after his death, when most of the details had been forgotten. The chief sources of biography are: (a) Records (legal, financial, parochial, &c.), such as the entry in the registers of the parish church at Stratford-on-Avon of his baptism on 26th April 1564, and his burial on 25th April 1616; records of payments in the accounts of the Lord Chamberlain for performances of the players at Court in which Shakespeare's name is mentioned; the signed depositions dated 11th May 1612, in the case of *Bellott v. Montjoy*, when Shakespeare gave evidence; the agreement to purchase property in the Blackfriars (now in the Guildhall); his last will (in Somerset House), signed on 25th March 1616. Shakespeare's name occurs frequently in such documents; they are the most valuable records of fact, but they throw little light on his personality. (b) Jottings and biographies. A brief biographical notice is to be found in *The Worthies of England* (1662) of Thomas Fuller (q.v.). John Aubrey, friend of Antony à Wood, collected in his *Brief Lives* (ed. A. C. Clark), a few anecdotes from William Beeston, an old actor (died 1682), whose father Christopher was a member of Shakespeare's company. Other stories and traditions are recorded by the Rev. John Ward, vicar of Stratford 1662-68, the Rev. William Fulman, Archdeacon Davies, John Dowdall, who visited Stratford in 1693, William Oldys the antiquary (1696-1761), and others. The first formal biography was written by Nicholas Rowe, the dramatist, and prefixed to his edition of Shakespeare's works in 1709. Rowe was much indebted to William Betterton, the Restoration actor, who had made a journey to Stratford to collect such traditions as still survived. Anecdotes first written down fifty to a hundred years after Shakespeare's death are naturally to be received with caution; but it is to be noted that most of Rowe's statements are confirmed from independent sources, which were not accessible to him. (c) Contemporary notices. There are many references to and quotations from Shakespeare's works in the writings of his contemporaries from which it is possible to estimate his growing reputation. (d) Shakespeare's own works. These are a dangerous source for the biographer. Shakespeare is so many-sided, and his characters are so diverse, that any attempt to distil 'the real Shakespeare' is largely a waste of labour, though several writers have made the attempt.

Shakespeare's father, John Shakespeare, was a leading citizen of Stratford, who about 1557 married Mary Arden, the youngest daughter of Robert Arden, a farmer of Wilmcote, near Stratford, a man of some means. William was the third child and the eldest son of a family of eight. John Shakespeare is variously described as farmer, glover, dealer in wool, and butcher; there was nothing unusual in this combination of trades. At the time of the poet's birth he was a man of comfortable means; in 1565 he was made an alderman, in 1568 he became bailiff—the highest municipal officer—and in 1571 chief alderman. After 1578, however, he took less part in the affairs of the town, and his business seems to have failed.

Little is known of Shakespeare's early life from the records. Rowe states 'He was the son of Mr John Shakespeare, and was born at Stratford-upon-Avon, in Warwickshire, in April 1564. His family, as appears by the register and other public writings relating to that town, were of good figure and fashion there, and are mentioned as gentlemen. His father, who was a considerable dealer in wool, had so large a family, ten children in all, that, though he was his eldest son, he could give him no better education than his own employment. He

had bred him, 'tis true, for some time at a free school, where, 'tis probable, he acquired that little Latin he was master of; but the narrowness of his circumstances, and the want of his assistance at home, forced his father to withdraw him from thence, and unhappily prevented his further proficiency in that language. Upon his leaving school he seems to have given entirely into that way of living which his father proposed to him; and, in order to settle in the world after a family manner, he thought fit to marry while he was yet very young. His wife was the daughter of one Hathaway, said to have been a substantial yeoman in the neighbourhood of Stratford.'

Shakespeare's marriage to Anne Hathaway was apparently a hasty affair, for on 28th November 1582 a special licence was issued to two friends of the Hathaway family to allow the marriage to take place upon once asking of the banns; Shakespeare was then aged eighteen, his wife twenty-six. On 26th May 1583 their first child, Susanna, was baptised in Stratford Church; and on 2nd February 1585 twins, Hamnet and Judith, were baptised. In 1589 Shakespeare's name is joined with those of his parents in some legal proceedings before the Queen's Bench. No other records of this period survive. Rowe continues: 'In this kind of settlement he continued for some time, till an extravagance that he was guilty of forced him both out of his country and that way of living which he had taken up. . . . He had, by a misfortune common enough to young fellows, fallen into ill company, and amongst them, some that made a practice of deer-stealing, engaged him more than once in the robbing a park that belonged to Sir Thomas Lucy of Charlecot, near Stratford. For this he was prosecuted by that gentleman, as he thought, somewhat too severely; and, in order to revenge that ill usage, he made a ballad upon him. And though this, probably the first essay of his poetry, be lost, yet it is said to have been so very bitter that it redoubled the prosecution against him to that degree that he was obliged to leave his business and family in Warwickshire for some time and shelter himself in London. It is at this time, and upon this accident, that he is said to have made his first acquaintance in the playhouse. He was received into the company then in being, at first in a very mean rank; but his admirable wit and the natural turn of it to the stage, soon distinguished him, if not as an extraordinary actor, yet as a very excellent writer. His name is printed, as the custom was in those times, amongst those of the other players, before some old plays, but without any particular account of what sort of parts he used to play; and, though I have inquired, I could never meet with any further account of him this way, than the top of his performance was the ghost in his own *Hamlet*.' Aubrey (who is usually unreliable) states, on the authority of Beeston, that 'he had been in his younger years a school-master in the country.' Dr Johnson tells the story that 'his first expedient [on coming to London] was to wait at the door of the playhouse and hold the horses of those who had no servants, that they might be ready again after the performance.' It is difficult to say how far these traditions are founded on fact. Sir Thomas Lucy did not keep deer at Charlecot, but as he certainly seems to be pilloried as Justice Shallow (in *The Merry Wives of Windsor*) who also bore 'lucres' (or 'louses' as Sir Hugh Evans calls them) in his coat of arms, there seems to have been some truth in the story. Apart from these traditions it is not known when or why Shakespeare came to London or what he was doing between 1585 and 1592 when the first reference to him occurs in Robert Greene's *Groatsworth of Wit bought with a million of repentance*.

Greene (q.v.), one of the most popular pamphleteers and dramatists of his time, had lived a life of alternate excess and repentance. In August 1592, as he was dying, he wrote a letter to 'Those Gentlemen his Quondam acquaintance that spend their wits in making plays' (identified with Marlowe, Nashe and Peele) in which he warns them against the ingratitude of the players whose fortunes the playwrights had made. 'Yes, trust them not; for there is an upstart Crow, beautified with our feathers, that with his *Tiger's heart wrapped in a Player's hide*, supposes he is as able to bumbast out a blank verse as the best of you; and being an absolute *Johannes fac totum*, is in his own conceit the onely Shake-scene in a country.' The line italicised is a parody of 'O tiger's heart, wrapt in a woman's hide,' from the third part of *Henry VI.* (I. iv. 137), and the natural inference is that Shakespeare had begun to make a name for himself by revising the work of other dramatists. When Greene died on 2nd September, some of his papers were hurriedly put together for the press by Henry Chettle and 'entered' for publication on 20th September. The book caused considerable stir, and Nashe was suspected by some of having been concerned in its issue, but he vigorously disclaimed any connection with this 'scald, trivial, lying pamphlet.' Apparently a protest was made on Shakespeare's behalf, for when Chettle published his own *Kind-heart's Dream* some weeks later, he remarks in the preface 'To the Gentlemen Readers' 'With neither of them that take offence was I acquainted, and with one of them I care not if I never be: the other, whom at that time I did not so much spare as since I wish I had, for that as I have moderated the heat of living writers, and might have used my own discretion, (especially in such a case)—the author being dead—that I did not, I am as sorry as if the original fault had been my fault, because myself have seen his demeanor no less civil than he excellent in the quality he professes. Besides, divers of worship have reported his uprightness of dealing which argues his honesty, and his facetious grace in writing that approves his art.'

Elizabethan drama was not regarded as literature. The players were concerned with the difficult task of making a living, and their relations with dramatists were strictly commercial. Plays were regarded as so much merchandise, and, more often than not, were written by two or more writers in collaboration. Once the manuscript was sold to the players, it became their absolute property, and they cut, revised, or added to it to suit their own convenience. Shakespeare began by refurbishing old plays, and afterwards he seems whenever possible to have used an old play as the basis of his own work. Nor did he hesitate to revise or rewrite his own plays. *Love's Labour's Lost* and *Troilus and Cressida*, for instance, contain signs of alteration at different periods, whilst in *Macbeth*, the second scene and other passages are probably revisions made to the play by some other dramatist after Shakespeare's retirement. These business methods cause much complication in estimating questions of date, style, and authorship. Generally speaking, however, there are certain tests which can be applied to determine the date of a play; they are—(1) external; (2) topical allusions (or 'gags') in the play itself which can be dated; and (3) the evidence of style.

(1) External evidence is of several kinds. A certain Francis Meres in 1598 wrote *Palladis Tamia* or *The Wits Treasury*, in which he tried to show that the writers of England were equal to the great writers of antiquity. 'As Plautus and Seneca are accounted the best for Comedy and Tragedy among the Latins, so Shakespeare among

the English is the most excellent in both kinds for the stage; for Comedy, witness his *Gentlemen of Verona*, his *Errors*, his *Love Labors Lost*, his *Love Labors Won*, his *Midsummers Night Dream*, and his *Merchant of Venice*; for Tragedy his *Richard the 2*, *Richard the 3*, *Henry the 4*, *King John*, *Titus Andronicus*, and his *Romeo and Juliet*.' This list fixes the latest date for the plays mentioned, and also establishes presumptive evidence that the other great plays, not in the list, are later. References and quotations in the works of other writers, which can be dated, also provide evidence. Entries in the *Stationers' Register* are most important. It was a regulation of the Stationers' Company (which included printers) that all books before publication should be entered in the hall-book of the Company. Many of Shakespeare's plays were thus entered during his lifetime, though not all the plays thus entered were printed immediately. As a general principle the players objected to the printing of their plays and sometimes they arranged that a play should be entered to prevent unauthorised publication; *As You Like It*, for instance, though entered on 4th August 1600 was not published until the First Folio 1623.

(2) The value of topical allusions varies. In the Prologue to *Henry V.*, reference is made to the departure of Essex for Ireland; in *Macbeth* (II. iii. 10) the remarks of the Porter, 'Faith, here's an equivocator, that could swear in both the scales against either scale, who committed treason enough for God's sake, yet could not equivocate to Heaven,' seem to be pointed at the famous plea of equivocation set up by Fr. Garnet the Jesuit, who was executed for complicity in the Gunpowder Plot. But topical allusions are not always reliable; a 'gag' must be kept up to date or it loses its point, and the players had no hesitation in making alterations in the text.

(3) The evidence of style is of considerable value. It is noticeable that in the early plays Shakespeare adheres rigidly to his metre, and his lines are 'end-stopped,' that is, the sense line corresponds with the verse line. As time went on, his use of metre became more and more free, until in the *Tempest*, his last play, it is almost rare to find an end-stopped line. In the early plays rhymed lines are frequent; they are used rarely in the later. Moreover, as time went on, the words became more densely charged with meaning. The change of style can be illustrated by brief quotations. In *Julius Caesar* (c. 1600) Caesar says:

Cowards die many times before their deaths;
The valiant never taste of death but once.
Of all the wonders that I yet have heard,
It seems to me most strange that men should fear;
Seeing that death, a necessary end,
Will come when it will come (II. ii. 86.)

In *King Lear* (c. 1606), a similar thought is condensed to:

Men must endure
Their going hence, even as their coming thither;
Ripeness is all. (V. ii. 11.)

The style of a play is naturally only a rough indication of date, but where there is general agreement between the external, internal, and stylistic evidences, a play can be dated with some accuracy.

Elizabethan players had to cater for two very distinct types of audience, the popular in their public playhouses, and the courtly at the houses of great noblemen or the court. Most of Shakespeare's plays were written for the public stages, but a few (such as *A Midsummer Night's Dream* and *Love's Labour's Lost*) were certainly intended for private performance.

Shakespeare's first dramatic work was to make additions and alterations to the old plays. The

three parts of *Henry VI.* are included in the editions of his works, but few of the scenes in these plays are of his writing. Other plays of this early period are *The Two Gentlemen of Verona*, *The Comedy of Errors*, *Titus Andronicus*, *The Taming of the Shrew*, *King John*, and *Love's Labour's Lost*.

Love's Labour's Lost is the most interesting of the group. It is probably the first play completely Shakespeare's; it was written for a private audience, and satirises certain prominent persons—probably Sir Walter Raleigh and his coterie. Much of the satire is now inexplicable, but there are some very fine poetical speeches put into the mouth of Berowne, particularly the defence of 'Barbarism' and the praise of love. Shakespeare made alterations to the play about 1598, the new and the old versions of the recast speeches being clearly discernible in the text. The play was again revived for Queen Anne, wife of King James I., in 1604.

Shakespeare definitely came to the fore in the spring of 1593 with the publication of *Venus and Adonis*, which was 'entered' on 18th April. The poem tells the story of Venus's unrequited passion for Adonis; it was a great success, and went into seven editions in nine years. *Venus and Adonis* is dedicated to Henry Wriothesley, 3rd Earl of Southampton and Baron of Titchfield. Southampton was then aged nineteen; he was the ward of William Cecil, Lord Burleigh, and was regarded as a young man of great promise. During the next twelve months an intimacy, which must have been close, developed between Shakespeare and Southampton. *The Rape of Lucrece*, which Shakespeare brought out in the next year, is also dedicated to Southampton, but the difference in tone in the second dedication is very noticeable. The friendship between player and nobleman apparently caused much unfavourable comment. In a book entitled *Willobie His Avisa* (1594) considerable scandal is retailed concerning a certain young man 'H. W.' and his familiar friend 'W. S.' the 'old player'; there can be little doubt that Wriothesley and Shakespeare are intended.

It is probable that many of the *Sonnets* were written about this time, though they were not published until 1609, and then apparently without Shakespeare's knowledge or consent. Most of them are addressed to a young man, who is the poet's patron (probably, though not certainly, the Earl of Southampton), the last twenty-seven are concerned with a 'dark lady' who was the poet's mistress. Without some new discovery it is not possible, in spite of the ingenuity of many critics, to say how far the story which the *Sonnets* tell is autobiographical, symbolic, or simply poetic fiction. It must be remembered that sonneteering was a fashion in the 1590's, and that 'the truest poetry is the most feigning.'

The year 1593 very definitely marks the end of the first period of Elizabethan drama. In the summer a severe epidemic of the plague broke out, the theatres were shut, and the players forced to go on tour. The plague continued for many months, and not until the summer of 1594 did playing begin again in London. Many changes had taken place. The two great dramatists of Shakespeare's apprenticeship had died—Greene in 1592, Marlowe on 30th May 1593; a third, Thomas Kyd, died in December. Moreover, the players' companies had been so reduced by the troubles of these months that complete reorganisation was necessary. When the plague subsided, the company best known as The Lord Chamberlain's Men (including Shakespeare, Richard Burbage the tragedian, Will Kempe the clown, Heming and Condell, afterwards the editors of the first folio of Shakespeare's works) was reformed, and took up its headquarters at The Theatre

in Shoreditch, which was owned by Burbage's father. The Chamberlain's Men, thanks to the combination of Burbage's skill with Shakespeare's drama, prospered, and soon became recognised as the leading company. During the next three years (1594-97) Shakespeare wrote *Richard II.*, *A Midsummer Night's Dream*, *All's Well that Ends Well*, *The Taming of the Shrew*, *The Merchant of Venice*, and *Romeo and Juliet*.

Several facts connected with Shakespeare's private life at this period are known. His only son Hamnet died, and was buried at Stratford on 11th August 1596. About the same time John Shakespeare, his father, applied to the Herald's College for the right to assume a coat-of-arms as a gentleman. A draft was prepared, but certain difficulties were raised, and the grant was not finally made until three years later. The arms assigned were 'Gold on a bend sable, a spear of the first, the point steeled proper, and for his crest or cognisance a falcon, his wings displayed argent, standing on a wreath of his colours, supporting a spear gold steeled as aforesaid.' The motto chosen was 'Non sans droict.' This coat-of-arms is carved above the effigy of Shakespeare in Stratford Church.

On 4th May 1597 Shakespeare bought New Place, one of the largest houses in Stratford, for £60—a considerable sum at the time. In this year the town of Stratford was in financial difficulties, and one of the leading citizens, Richard Quyny, was despatched to London to plead for relief and help. A considerable body of correspondence relating to Quyny's mission survives at Stratford, in which Shakespeare is several times mentioned; it includes a letter written on 28th October 1598 by Quyny to Shakespeare, in which he asks for a loan of £30. It is clear from these records that Shakespeare was now a man of means, and highly regarded by his fellow-townsmen. In 1602 he purchased 107 acres of arable land at Stratford for £320; and in 1605 he paid £440 for a half-share of the Stratford tithes.

In April 1597 the lease of the ground on which The Theatre was built expired, and owing to disputes with the landlord the company was obliged to move to The Curtain, another playhouse in the Shoreditch neighbourhood. Here probably were first acted the two parts of *Henry IV.* and *Henry V.*

The two parts of *Henry IV.* and *Henry V.* form a trilogy; they are based on Holinshed's *Chronicles*, a favourite source for historical drama, and an old play, *The Famous Victories of Henry V.* In writing the first part, Shakespeare may be said for the first time to have reached perfection in his craftsmanship. The main story deals with the rebellion of Henry 'Hotspur' and his death at the hands of Prince Henry at the battle of Shrewsbury. The historical characters are admirably drawn and every scene lives, but all are dwarfed by the gigantic bulk of Sir John Falstaff, the greatest comic character in all literature. When first produced, the fat knight was called Sir John Oldcastle. The real Oldcastle was executed for Lollardy under Henry V., and his descendant Lord Cobham protested against this libellous representation of his ancestor. The name was then altered to Falstaff, from Sir John Fastolfe, one of the English commanders in France during the reign of Henry VI. In the second part of *Henry IV.* more of Falstaff's disreputable friends are introduced, including Doll Tearsheet, a prostitute, and Ancient Pistol, whose peculiar vocabulary is made up of scraps of bombastic phrases misquoted from the plays of other companies. It is not surprising that the Admiral's Men—the chief rivals of the Chamberlain's—should have answered by

setting their playwrights at work on a 'true and honourable history of the life of Sir John Oldcastle, the good Lord Cobham.' Falstaff is shown as Prince Hal's companion in roguery in the first part; but in the second he has less to do with the prince. When King Henry IV. dies and the prince succeeds to the throne Falstaff is rejected, and, as we are told in *Henry V.*, dies of a broken heart. Falstaff is so lovable a rogue that it is difficult to forgive the king; but it must be granted that he brings his dismissal on himself by appearing at a most inopportune moment, and even Shakespeare could scarcely have found a suitable place for him in the Council of State.

Henry V. is sometimes called Shakespeare's ideal king, and rival critics attack or applaud his character according to their preference for the man of thought or the man of action. Shakespeare, however, had no illusions about the real nature either of Henry V. or of his father; he makes both of them, in moments of candour, acknowledge themselves to be usurpers, and he shows quite frankly that Henry V. accepted the advice of his dying father to make war on France in order that public opinion might be distracted from prying too closely into his crooked title to the throne.

Rowe records the tradition that Queen Elizabeth was so taken with Falstaff that she ordered Shakespeare to write another play showing him in love. The result was *The Merry Wives of Windsor*, written in fifteen days. Careful examination of the text confirms Rowe's story; the play was founded on an old comedy of intrigue which was rewritten in haste. Both *II. Henry IV.* and *The Merry Wives of Windsor* are full of references to Shakespeare's own home county.

The dispute between the Chamberlain's Men and their landlord over the tenancy of The Theatre still continued, and it became clear that unless something drastic was done, the valuable building material and fittings would be lost to the company. Accordingly, at the end of December 1598, they leased a piece of ground on the south side of the Thames near Southwark Cathedral. This done, they proceeded, with the aid of a builder and his men, to tear down the timber structure of The Theatre for use in the construction of a new playhouse—the famous Globe. The Globe was completed in the summer of 1599 and thither the Chamberlain's Men moved.

The usual financial arrangement at an Elizabethan theatre was for the receipts to be divided between the players and the owners of the building, technically known as the 'housekeepers.' The players' portion was then subdivided into shares among the individual members of the company. When the Globe Theatre was built it was necessary to raise new capital; the money was found by the players themselves, with the result that Shakespeare became a 'housekeeper' in the new theatre, and so drew shares both as actor and as owner.

Amongst the first plays to be staged in the new theatre were the three romantic comedies, *Twelfth Night*, *Much Ado About Nothing*, and *As You Like It*.

Of these *Twelfth Night* is the best constructed of all Shakespeare's comedies; the plot is complicated, and, as usual, there are several stories running side by side—the adventures of Viola and her twin brother Sebastian, the gulling of Malvolio and the misfortunes of Sir Andrew Aguecheek; but the various plots are so skilfully blended that they form a complete and integral whole. Viola is perhaps the deepest of all Shakespeare's heroines, and more than once the play verges on tragedy. The use of song is noteworthy, especially in Act II. scene iv., where the clown, by singing 'Come away,

come away, death,' creates the right emotional atmosphere for Viola's indirect, but moving, declaration of her love for Orsino.

Much Ado About Nothing, though a most successful play on the stage, is not so well constructed. The play begins with the return of Don Pedro and his officers, Benedick and Claudio, from the wars. Claudio, having fallen in love with Hero, the daughter of Leonato, governor of Messina, asks Don Pedro to woo the lady and her father for him. While he is waiting for the result, Don John, the prince's bastard brother, a thorough-paced villain, persuades Claudio that Don Pedro is wooing for himself. It appears as if the usual dramatic complications and misunderstandings are to follow, but, before Claudio has time to protest, everything is satisfactorily explained, and Claudio and Hero are betrothed. But a more serious problem is that, as the plot stands, the evidence offered to Claudio that Hero is unfaithful to him before marriage is so slight that his behaviour is incredible. The most probable explanation is that the play contains two *strata*, the Hero-Claudio plot being the original story. When rewritten about 1599, Shakespeare elaborated the characters of Benedick and Beatrice, and was thus obliged to compress the earlier plot to make room for the additions. This theory is supported by the fact that the Hero-Claudio scenes contain passages of verse written in Shakespeare's earlier manner, while the rest of the play is mainly in prose. It is, however dangerous to dogmatise on Shakespeare's use of prose and verse. When Beatrice has been persuaded that Benedick loves her, she breaks out into a soliloquy of ten-rhymed lines. The effect, doubtless not an accident, is to show Beatrice's character in an entirely new light; her 'maiden pride' and 'wild heart' were assumed, the real Beatrice is as romantic and maidenly as any.

As You Like It has often been acclaimed as a piece of wholly joyous pastoral comedy. More probably it is a subtle satire on pastoralism. Rosalind, disguised as a forester, Corin, Sylvius, and Phebe are conventional pastoralists, but two real yokels, William and Audrey, are introduced to show the difference between reality and romance. The whole question of the advantages of the shepherd's life is debated by Touchstone and Corin at some length; and Jaques is of opinion that life under the greenwood tree is only fit for the gross fools who suffer such discomforts as winter and rough weather 'a stubborn will to please.' There is, too, a genial cynicism about the play, especially in Rosalind's homilies on love, which suggests that both Shakespeare and the audience for whom he was writing were beginning to reject the conventional values of the romance writers.

At this time a notable change can be seen in Shakespeare's dramatic style and method. In the earlier plays he is interested chiefly in plot and story; in the period 1600 to 1607 he is more interested in character. There was indeed a very general interest in psychology in the first quarter of the 17th century, and on the stage a new era opens with Ben Jonson's play, *Every Man in His Humour*, first played at The Curtain in September 1598, in which Shakespeare took a part, probably that of Edward Knowell, senior. Other changes were taking place in theatrical conditions at this time. Two companies of boy actors, recruited from the choir boys of the Chapel Royal and St Paul's, were acting at the private theatres in Blackfriars and Whitefriars, where they were enthusiastically patronised by a fashionable and critical audience. The tone of these private playhouses, in contrast to the general rowdiness of the public theatres, introduced several new elements into English drama; criticism became keener,

taste improved, and gentlemen authors were attracted to turn dramatist. Accordingly, a new interest arises in 'problem plays,' which are usually tragedies, and comedies of 'humours,' wherein certain types of character are analysed, dissected, and satirised.

There is little trace of this new psychological interest in *Twelfth Night*; it is noticeable in the 'humours' of Beatrice and Benedick in *Much Ado About Nothing*; it becomes prominent in *As You Like It*, wherein the melancholy Jaques is a most important character, and yet has no place in the development of the plot. He exists simply as a most delightful study of the 'melancholic humour.' Shakespeare, however, reacted to the movements of taste and thought by instinct; unlike his great contemporary Ben Jonson, he was never a slave to critical theories.

About 1600 Shakespeare returned to tragedy, and in the next six years he wrote *Julius Cæsar*, *Hamlet*, *Othello*, *Macbeth*, and *Lear*.

Julius Cæsar and the other Roman plays (*Antony* and *Cleopatra* and *Coriolanus*) are founded on Plutarch's *Lives of the Noble Grecians and Romans*, nobly translated into English by Sir Thomas North, from the French version of Amyot. Plutarch (q.v.) was interested rather in character than in scientific history; and his 'Lives' are full of picturesque anecdotes, which provide admirable material for the dramatist. *Julius Cæsar* is the tragedy rather of Brutus than of Cæsar. Brutus is shown as an idealist and a patriot, but he lacks imagination and a practical knowledge of common things. He is led by the more practical Cassius into the plot against Cæsar, but once he has joined the conspirators he takes the lead and is responsible for its ultimate failure. After Cæsar's assassination, the play is concerned with the rise of Antony and the failure of the conspiracy in the deaths of Cassius and Brutus. Cæsar is portrayed as a somewhat superstitious tyrant who is beginning to fail, physically and mentally. This treatment of the great dictator has been much criticised, but it is probably historically accurate and certainly dramatically true; had Cæsar been represented otherwise, there could have been no justification for Brutus.

Hamlet is from nearly every point of view the most interesting of all Shakespeare's plays. It was founded on an old play (possibly by Kyd), and no less than three early versions exist. The first (known as the First Quarto, 1603) is a pirated text, either taken down in shorthand at a performance or else put together from memory. This version differs in many respects from the final version, and it preserves large passages written in an early style. Probably it represents a poor transcript of the play, made at a time when Shakespeare had partially rewritten the old drama but had still left many lines unrevised. The Second Quarto, 1604, was then published 'according to the true and perfect copy': it gives the play substantially as printed in a modern edition. It is now generally held that this quarto was set up direct from Shakespeare's own manuscript, and retains many of his spellings. The third version is that in the First Folio, 1623: it omits some passages and adds a few others. Modern editions of *Hamlet* are made up of a combination of the Second Quarto and the First Folio. The character of Hamlet has been much debated, and in every generation critics have held different views. Goethe declared that 'it is clear that Shakespeare sought to depict a great deed laid upon a soul unequal to the performance of it. . . . Here is an oak-tree planted in a costly vase, which should have received into its bosom only lovely flowers; the roots spread out, the vase is shivered.' The general impression formed by

critics of the 19th century was that Prince Hamlet, though endowed with every virtue, was unfortunately cursed with an oversensitive mind which betrayed him into reflection every time action was needed. It is doubtful whether such a character would have been understood in Elizabethan times. The 'problems' are much reduced when it is remembered that *Hamlet* belongs to a well-known type of Elizabethan drama—the Revenge Play. A Revenge Play had certain conventions which were quite familiar to playgoers who expected the venger to be faced with many obstacles before he finally reached his victim.

Macbeth (1603–6) is the tragedy of a conflict in a man's soul between imagination and ambition. Macbeth's ambitions are boundless, but until his wife urges him on they are checked by his finer feelings. He murders his king while a guest in his own castle, but he can never stifle his imagination, which betrays him again and again, until he envies the dead Duncan for being at peace. The play is somewhat uneven, and contains work which is not Shakespeare's, but the soliloquies, the 'atmosphere' of the murder-scene, and the dramatic irony, especially of the sleep-walking scene, are nowhere surpassed.

In *Othello* (performed at court on 1st November 1604) Shakespeare is concerned with the terrible results which follow when good but simple-minded men and women are unconsciously brought into conflict with an evil and subtle villain. Iago's apparent joy in villainy is not entirely motiveless, nor is it the malignity of one who has chosen evil to be his good: its source lies rather in disappointed vanity. At the beginning of the play he has been passed over in favour of Cassio, whom he despises, but he refuses to face the truth that Othello has chosen the better man. Instead, his vanity suggests that he has suffered impossible wrongs both from Cassio and Othello, and it urges him to blast the happiness of his adversaries in order that he may convince himself, cost what it may, that he is the real master of their fate.

King Lear is Shakespeare's sublimest tragedy, and in it man seems to be at the mercy of careless powers 'who kill us for their sport.' The story of the old king and his three daughters was well known in English literature, and had already been acted on the stage. In all the other versions the ending is happy, but in Shakespeare's play the passions roused are so stupendous that no happy ending is possible. In this play, too, the one character who clearly sees his own purpose is the evil Edmund, the bastard, whose mind has been warped by his crooked birth, and who from the first turns to Nature—the law of the wild beast—as his goddess. The play is so moving that it becomes almost intolerable when acted, the blinding of Gloucester being especially shocking to a modern audience. Shakespeare's audiences, more used to such scenes, seem not to have been excessively affected by the tragedy, for it was chosen as one of the plays to be acted as part of the Christmas festivities at court on 26th December 1606. After the Restoration, however, taste had changed, and from 1681 until the 19th century English audiences had to be content with the rewritten version of Nahum Tate, in which all ends happily with Cordelia married to Edgar, and Lear placed in comfortable retirement with Kent and Gloucester.

Two other plays, in their present form, probably belong to this period, *Troilus and Cressida* and *Measure for Measure*; each is full of problems for the scholar, and in each there seem to be many lines which are either early work or else not from Shakespeare's pen. *Troilus and Cressida* has never been a favourite, though Ulysses's words

to the Greek generals on 'Degree' and to Achilles on 'Ingratitude' are among Shakespeare's finest set speeches. It has offended critics because it refuses to fit into any critical category, and, too, because the Greek and Trojan heroes are represented as utterly degraded; their story is, in Thersites's words, 'nothing but lechery, all incontinent varlets.' Hector, the only fine character, is treacherously murdered by Achilles, and the play ends with the cynical comments of Pandarus on his trade of go-between. *Measure for Measure* begins as a problem play. Claudio, the brother of Isabella, who is about to enter the cloister, is condemned to death for incontinency. Isabella pleads for his life to Angelo, the austere deputy, but his usually cold nature is so stirred to lust by her beauty that he offers to save Claudio at the price of her chastity. She visits Claudio in prison, expecting that he will uphold her honour, but the thought of immediate death is too much for him, and, when he begs her to sacrifice herself to save his life, she turns from him with loathing. The question whether Isabella's chastity is worth more than Claudio's life is thus fully and frankly put. But instead of giving any answer Shakespeare sets in motion all the cumbrous machinery of disguised dukes and substituted lovers, and thus brings about a 'happy' ending.

Meanwhile the whole circumstances of the acting profession had changed for the better. On 24th March 1603 Queen Elizabeth died. Her successor, King James I., and his family encouraged men of letters, and within a few weeks of his accession he became patron of the Chamberlain's Company, who were henceforth known as the King's Men, their licence under royal letters patent being issued on 19th May. Nine members of the company are mentioned by name, Shakespeare coming second in the list. The players were now officially recognised as royal servants, and ranked as grooms of the chamber. Under the new king almost four times as many plays were performed at court as under Queen Elizabeth.

Before King James was able to make his royal progress through London the plague again broke out; the theatres were closed, and the King's Men were obliged to go on tour. In November they were summoned from Mortlake to the court, which was then at Wilton, the residence of William Herbert, Earl of Pembroke, and performed there on 2nd December. The court moved to Hampton Court for Christmas, and the King's Men acted six times. On 8th February a royal grant of £30 was made, 'by way of his Majesty's free gift,' to Burbage 'for the maintenance and relief of himself and the rest of his company being prohibited to present any plays publicly in or near London by reason of the great peril that might grow through the extraordinary concourse and assembly of people.'

The postponed royal progress was held on 15th March 1604. As royal servants the King's Men were granted 4½ yards of red cloth for a new livery at the charge of 'The Master of the Great Wardrobe' in honour of the occasion; there is, however, no evidence that they walked in the procession. In the list of the company receiving this grant Shakespeare's name stands first. In the following August the players, in their capacity as grooms of the chamber, were ordered to attend at Somerset House on the Constable of Castile, who had come to London at the head of the Spanish diplomatic mission to ratify the treaty of peace between England and Spain.

The great tragedies, as a group, are plays of character. They were followed by two Roman plays, *Antony and Cleopatra* and *Coriolanus*; both were based on North's Plutarch, and it is remarkable how closely Shakespeare kept to his source,

especially in the death of Cleopatra (V. ii.) and the speech of Volumnia to Coriolanus (V. iii. 94).

Antony and Cleopatra continues the story where *Julius Caesar* ended. Antony is shown as a tragic failure: he has become a 'strumpet's fool,' and he gradually loses his manhood and even his common sense. The play suffers somewhat from the great number of the scenes—there are seventy-one—but it contains some magnificent episodes, and, as always in the later plays, sublime poetry. A noteworthy feature is the subtle way in which Shakespeare uses the minor character of Enobarbus to comment on the action as it proceeds. To him is assigned the wonderful description of Antony's first meeting with Cleopatra, which is all the more striking because it is the tribute of a rough soldier who is usually very candid in his comments. In the end Enobarbus deserts his master, who sends after him all his treasure with bounty added. This nobility of Antony overwhelms Enobarbus, who dies of a broken heart.

Coriolanus is, again, a play of character, though the characterisation is less prominent. Coriolanus is a soldier, body and soul, who can only think and act in terms of war. He has neither sympathy nor understanding for the citizens of Rome, because he knows that they are inconstant in peace and unreliable in war. His natural pride is increased by the fierce mother Volumnia, who exults in his wounds and has the utmost scorn for his wife Virgilia, whose only thought is for the safety of her man. The crowd, as are all Shakespeare's crowds, is fickle and easily influenced by anyone who sets himself out to please it; but it is wrong to maintain, as do some critics, that Shakespeare's sympathies in this play are anti-democratic or aristocratic. Here as always he is impartial.

In 1608 the King's Men acquired the private theatre in the fashionable quarter of Blackfriars. This playhouse had originally been constructed by James Burbage in 1597, at the beginning of the dispute over The Theatre, but the neighbours, who were all people of influence, objected to the presence of common players, and so the playhouse was leased to the Children of the Chapel Royal, nominally as a rehearsal-room. The Children on several occasions offended by acting plays which openly satirised important persons, including the King himself, and more than once they had been restrained; but in 1608 they were finally suppressed for acting Chapman's *Tragedy of Charles, Duke of Byron* (a play dealing very frankly with life at the French Court), after formal prohibition. The old opposition to the professional players had now almost died down, and the King's Men occupied the theatre. Blackfriars was a small private playhouse in which plays were acted indoors by artificial light; the audience was select, and the prices charged for admission were high. Henceforward the King's Men acted at the Globe in the summer months and at Blackfriars in the winter. The new scheme was financed by seven of the company, of whom Shakespeare was one; it was a most prosperous venture.

Towards the end of his dramatic career (c. 1609–1611), Shakespeare reverted to his early method in the three plays, *Cymbeline*, *The Winter's Tale*, and *The Tempest*; the interest in plot and character being once more evenly balanced. In each the outlook is similar: wrongs committed by one generation are reconciled in the next. These plays belong to the type known as tragi-comedies: the theme is tragic but the ending happy. There can be little doubt that Shakespeare was influenced by the new dramatic methods of the two rising dramatists, Beaumont and Fletcher (q.v.).

The Tempest, probably his last play, shows Shakespeare's power at its highest; there is

neither the deep tragedy of *Lear* nor the pessimism of *Timon*, nor the light-heartedness of the romantic comedies; but, if indeed Shakespeare ever projects his inmost feelings into his dramas, it is in *The Tempest* that we find his maturest philosophy of life. Prospero has none of the Christian hope in immortality:

We are such stuff as
Dreams are made on, and our little life
Is rounded with a sleep.

He knows that Miranda's joy at the discovery of a brave new world is the enthusiasm of youth as yet inexperienced; but above all he has found that 'the rarer action is in virtue than in vengeance.' The play was performed at court in February 1613 as part of the wedding festivities of Princess Elizabeth and the Elector Frederick.

It is not known when Shakespeare retired from the stage and returned to live at Stratford. There are several lists of the King's Men compiled from various sources. In May 1605 one of the company, Augustine Philips, died and left bequests to his fellow-actors, including Shakespeare. This is the last time his name occurs in a list of the players; he did not, apparently, take a part in Jonson's play, *The Alchemist*, in 1610. The usual date given for his retirement is 1611; more probably he left the stage earlier, but to the end of his life he kept in close touch with his fellows. John Shakespeare, his father, had died in 1603. On 5th June 1607 his elder daughter Susanna married John Hall, of Stratford, a well-known physician. His mother died in September 1608. Several traditions are recorded of Shakespeare's last days at Stratford. Rowe says: 'The latter part of his life was spent, as all men of good sense will wish theirs may be, in ease, retirement, and the conversation of his friends. He had the good fortune to gather an estate equal to his occasion, and, in that, to his wish; and is said to have spent some years before his death at his native Stratford. His pleasurable wit and good nature engaged him in the acquaintance and entitled him to the friendship of the gentlemen of the neighbourhood.' The Rev. John Ward, vicar of Stratford in 1662, noted: 'I have heard that Mr Shakespeare was a natural wit without any art at all; he frequented the plays all his younger time, but in his elder days lived at Stratford and supplied the stage with two plays every year, and for that had an allowance so large that he spent at the rate of a thousand a year, as I have heard. Shakespeare, Drayton, and Ben Jonson had a merry meeting, and, it seems, drank too hard, for Shakespeare died of a fever there contracted.'

In March 1613 Shakespeare purchased a house in Blackfriars, near the playhouse which involved him in a lawsuit two years later to force the vendor to surrender the title-deeds. In June the Globe Theatre was burnt to the ground during a performance of *Henry VIII.*; a new and finer house was erected on the ruins. On 12th July 1614 John Combe, a wealthy Stratford man, died and left many bequests to his friends, mostly persons of considerable local standing; Shakespeare received £5. Combe's nephews succeeded to the property and proposed to enclose some of the common land belonging to the borough; both sides referred the dispute to Shakespeare, but he remained neutral.

On 25th January 1616 Shakespeare had caused a draft will to be prepared, but it was not signed at the time. On 20th February his younger daughter Judith married Thomas Quyny, son of Shakespeare's old friend Richard Quyny. Soon after, he became dangerously ill; the draft will was revised and signed on the 25th March. No mention is made of his wife, except that, by an addition made to the original draft, she was given his second-best bed with its furniture. She was legally entitled to a

third share of the freehold estates. Susanna Hall, the elder daughter, received New Place and the greater portion of the property; Judith the younger received his broad silver-and-gilt bowl and £150 in money, with a further £150 to be paid within three years. Various small bequests were made to Stratford friends, and to his fellows, Heminge, Burbage, and Condell, he left 28s. 6d. to buy memorial rings.

Shakespeare died on 23rd April 1616, and was buried in the chancel of Stratford on the 25th. It is said that the grave was dug seventeen feet deep to prevent disturbance. The crude inscription over the grave runs—

GOOD FRIEND FOR IESUS SAKE FORBEARE
TO DIGG THE DUST ENCLOSED HEARE:
BLESTE BE YE MAN YT SPARES THES STONES,
AND CURST BE HE YT MOVES MY BONES.

Shortly after Shakespeare's death a mural monument, which includes a half-length effigy, was made by Garratt Janssen, or Johnson, a tombmaker of Southwark, and set up on the north wall of the chancel of Stratford Church. This bust and the somewhat crude engraving in the First Folio are the only portraits of Shakespeare which can claim to be genuine. A painting (now in the art gallery of the Memorial Theatre at Stratford) is by some considered the original of the engraving, but more probably it is a copy.

Six signatures exist on documents, and it is now believed that three pages of a manuscript play called *The Book of Sir Thomas More* are in Shakespeare's hand. There is, however, nothing remarkable in the absence of manuscripts; no specimens at all remain of Shakespeare's contemporaries, Marlowe and Greene.

The Growth of Shakespeare's Fame.—At the time of his death sixteen of the plays had been separately published in quarto. Seven years later, in 1623, John Heminge and William Condell, two of Shakespeare's fellow-actors, with the help of the 'stationers' Blount, I. and W. Jaggard, Smethwicke and Aspley, produced a collected edition of the plays (with the exception of *Pericles*) in one folio volume—the First Folio. The First Folio marks the real beginning of Shakespeare's literary fame. It was dedicated to the Earls of Pembroke and Montgomery, and includes a notable elegy by Ben Jonson, memorial verses by various admirers, and a preface addressed 'To the Great Variety of Readers,' in which Heminge and Condell declare that 'his mind and hand went together; and what he thought, he uttered with that easiness, that we have scarce received from him a blot in his papers'—a remarkable tribute to Shakespeare's spontaneity.

The First Folio was reprinted in 1632 with some memorial poems, including one by J[ohn] M[ilton]. In 1640 acting was forbidden, and the theatres remained closed for twenty years during the troubles of the Civil Wars and the Commonwealth. After the Restoration the Folio was reprinted in 1665-66 with additional plays (not Shakespeare's work) and again in 1683. At this time Shakespeare's fame was in a transition stage; he was neither a modern nor a classic. Critics, obsessed with the rules of the classical school, condemned his lack of 'art,' yet they recognised his genius, and there was considerable controversy whether Beaumont and Fletcher, Jonson or Shakespeare were to be reckoned the greatest dramatist of the preceding age. The whole question is discussed in Dryden's admirable *Essay of Dramatic Poesy* (1668). Shakespeare's plays, usually much 'adapted,' were often played in the Restoration theatres, but, as literary men more and more ceased to be interested in the art of the theatre,

the plays became regarded rather as literature than drama. In 1709 Shakespeare definitely became a classic when Nicholas Rowe (q.v.) published the first edited collection of the works. In the earlier editions—the quartos and folios—the text is printed in a most haphazard manner. The acts are seldom divided into scenes, and in some instances there is no division even into acts. Nor are there, with very few exceptions, any place-headings to the scenes. Rowe was the first to reduce the text to consistency, and, until recent years, most editors have in the main followed his lead. Rowe's edition was reprinted in 1714. In the first half of the 18th century other editions were brought out by Pope (1723–25, 1728, 1731, 1735), Theobald (1733, 1740, 1752, 1762), and Hanmer (1740, 1743, 1744–46, 1745, 1747, 1748, 1750–51). Dr Johnson's edition was published in 1765.

Modern scholarship begins with Edmund Malone. Though not a first-class critic he was a great antiquary; he made a large collection of early plays and pamphlets (now in the Bodleian Library, Oxford), and he wrote an admirable account of the Elizabethan stage.

At the beginning of the 19th century Shakespearean criticism enters on a new era with the revival of the interest in romance. Lamb, in his notable essay on *The Tragedies of Shakespeare* (1811), boldly asserted that the tragedies were too great to be acted. In 1817 Coleridge delivered some lectures on Shakespeare, which mark the beginnings of the 'Bardolatry' of the 19th century. 'Assuredly,' he said, 'that criticism of Shakespeare will alone be genial, which is reverential. The Englishman, who without reverence, a proud and affectionate reverence, can utter the name of William Shakespeare, stands disqualified for the office of critic.' The most noticeable characteristic of the great volume of aesthetic criticism which followed during the Victorian era, both in England and Germany, is the tendency of critics to regard Shakespeare's characters as real persons, and to analyse and appraise their motives and characters accordingly.

Meanwhile scholars had been studying the work of Shakespeare's contemporaries. Editions of Jonson, Massinger, and Ford were produced by Gifford, and of Greene, Marlowe, Peele, Middleton, Beaumont and Fletcher, and Webster by Dyce, a most accurate scholar. In 1841 was founded the Shakespeare Society, which for some years published studies of Elizabethan life and reprints of the popular literature of Shakespeare's time. The director of the society was J. Payne Collier (q.v.), the most learned Shakespearean scholar of the century. Unfortunately Collier's enthusiasm outran his honesty; when evidence to support his theories was not forthcoming he forged or invented the necessary documents. With the exposure of Collier's practices the society collapsed. In 1874 a New Shakespeare Society was founded. Its chief work was the discovery and application of the metrical tests, which resulted in the establishment of the general order of Shakespeare plays. At the same time a notable work of aesthetic criticism was *Shakespeare: His Mind and His Art* (1874) by Edward Dowden, who combined considerable critical ability with a wide knowledge of Elizabethan literature. Dowden sets forth the somewhat debatable theory that Shakespeare's biography can be traced in the varying moods of his plays. The final and in many ways the best piece of criticism on Victorian lines is *Shakespearean Tragedy* (1904) by A. C. Bradley.

In the 20th century there have been great developments in Shakespearean scholarship. W. W. Greg, by his scholarly editions of the *Diary* and

Papers of Philip Henslowe (1904–7) gave a new stimulus to the study of Elizabethan stage conditions. Philip Henslowe owned the Rose and the Fortune Theatres, at which his son-in-law, Edward Alleyn, the leading actor of the Admiral's Men (the chief rivals of the Chamberlain's Men), acted. Henslowe financed the companies acting at his playhouses, and in his *Diary* are recorded the detailed accounts of the payments made on behalf of the players to their dramatists, tailors, and other purveyors of the theatre for the years 1591 to 1601. Knowledge of the dramatic conditions of Shakespeare's theatre was further advanced by Sir E. K. Chambers's great compilation, *The Elizabethan Stage* (1923).

In the present century the study of bibliography and palaeography has developed into a science. A renewed interest in the early texts of Shakespeare was awakened by Percy Simpson's discovery that the punctuation of the Folio was dramatic and not grammatical, and that in many instances the pointing in the early texts showed how the Elizabethan actor enunciated his lines. In 1916 Sir E. Maunde Thompson, in writing his article on 'Shakespeare's Handwriting' for the Tercentenary publication *Shakespeare's England*, was led to re-examine the manuscript play *The Book of Sir Thomas More*. The play is the work of several dramatists, and includes a crowd scene of three pages. It was suggested so early as 1871 that this scene was worthy of Shakespeare. Maunde Thompson now came to the conclusion, on palaeographical grounds, that the writing in these pages was Shakespeare's. The theory was further developed in *Shakespeare's Hand in Sir Thomas More* (1923), and is now widely though not unanimously accepted. A. W. Pollard's *Shakespeare's Fight with the Pirates* (1920) is perhaps the most important landmark in recent study. Pollard showed that the early quartos were, in all probability, set up direct from Shakespeare's own manuscripts, and that their mistakes were often due to the peculiarities of the printer's copy. The result of these investigations has been to establish new principles of textual criticism. At the present time a new text—*The New Shakespeare*—is being published, volume by volume, under the textual editorship of J. Dover Wilson.

Shale is any argillaceous rock which splits into thin laminae in the plane of sedimentation—a kind of lamination not to be confounded with the fissile structure seen in clay-slate (see SLATE). Shale is composed mainly of alumina and silica; but some shales are rich in carbonate of lime (calcareous shale), others contain much ferric oxide (ferruginous shale). Those shales which contain much quartz pass into shaly sandstone. When carbonaceous matter is abundantly present shale often passes into gas-coal, or, it may be, bituminous shale. When it is remembered that shale is of sedimentary origin, and was washed down in the form of fine silt from the land to be accumulated in lakes and quiet areas of the sea-bottom, as in estuaries and protected bays, its variable composition will be readily understood. Shales are frequently highly fossiliferous—the fossils, owing to the impermeable character of such argillaceous rocks, being generally well preserved. Decomposing shales, through which sulphide of iron is disseminated, are valuable for the manufacture of Alum (q.v.).

Bituminous shales—i.e. shales more or less rich in carbon and hydrogen—have for many years attracted much notice as sources of oil for illuminating purposes. Two manufacturing chemists, Butler in 1833 and Du Buisson in 1845, worked patents for the extraction of paraffin from coal-tar. The process introduced by the latter in France of distilling certain bituminous shales at a comparatively low temperature was afterwards tried in England, being used for a time in distilling a Dorsetshire bituminous shale, sometimes called 'Kimmeridge coal.' From this mineral a burning oil, a lubricating oil, and a naphtha for dissolving caoutchouc were obtained. But neither in France nor in England did the attempt to make a profitable manufacture succeed: in the former country the poverty of the shales was the chief drawback; in the latter the disagreeable smell of the oil, which could not be effectively removed, prevented it from obtaining favour in the market.

On account of these failures the process fell into abeyance, until it was revived again by the success of the well-known patent of James Young (see PARAFFIN), secured in 1850 for the production of paraffin and paraffin-oil from coal. With the exception of the solid paraffin, which Young was the first to obtain on the large scale, and the employment of cannel coal instead of shale, the processes of Du Buisson and Young are essentially the same.

After experimenting with many varieties of coal, Young found the 'Boghead or Torbanehill mineral' most suitable for his purpose. It yielded about 120 gallons of crude oil per ton. Twelve years of mining led to the exhaustion of the Boghead seam, and then attention was directed to the bituminous shales of the Lothians, usually called 'oil shales.'

A good oil shale can be distinguished from ordinary shale, or 'blaes,' by its dark-brown colour and streak, by its toughness, and by its resistance to the disintegrating action of the weather; it can be readily cut and curled up in thin shavings with the edge of a sharp knife. Oil

shales are finely laminated, the lamination being best seen in the 'spent shale' after distillation. There has been much discussion as to the nature of the bituminous material, termed *kerogen* by Crum Brown. Conacher's researches indicate that the oil substance is chiefly resin derived from wood.

The rich shales first used yielded 40–50 gallons of crude oil per ton; later the yield fell to 30–35 gallons. In addition to crude oil, the distillation of the shale gives gas, used as fuel, and ammoniacal liquor. The crude oil, after refinement by repeated distillation and by chemical treatment, gives the following products: Shale spirit or naphtha, lamp and power oils, gas oils and fuel oils, lubricating oils, solid paraffin used for candle-making, &c., coke, gases used for illuminating neighbouring towns and villages, &c. From the ammoniacal liquor is obtained a very valuable by-product, sulphate of ammonia, which finds a ready market not only in Britain, but also in Japan and the United States. The Scottish oil industry has had a long and increasingly intense struggle for existence against the competition of the world's oil-fields; yet, 2,857,104 tons of shale were mined in 1924.

Shaler, NATHANIEL SOUTHGATE (1841–1906), American geologist, graduated at Harvard University, where he was professor of paleontology 1868–87, and then professor of geology. He wrote *Nature and Man in America* and other scientific works.

Shalloon, a light worsted cloth, believed to have been first made at Châlons-sur-Marne.

Shallot, also ESCHALOT (*Allium Ascalonicum*), a species of Allium—Onion—(q.v.), a native of the East, introduced into Europe by the Crusaders—from Ascalon, it is said—and much cultivated for its bulbs, which are used like those of the onion, and sometimes for its leaves, which are used like those of the chive. The leaves grow in tufts like those of the chive, but are larger. The shallot is generally propagated by the cloves, which are planted just beneath the surface of the ground, or only partially beneath it, in spring, and the crop is ready for gathering in July or August. The flavour resembles that of garlic, but is much milder. In the vineyards of Italy the shallot is naturalised.

Shalmaneser, the name of four kings of Assyria (q.v.), three of whom are celebrated for their military exploits.

Shaloo. See DURRA.

Shama. See CAGE-BIRDS.

Shamanism, a name applied loosely to the religion of the Turanian races of Siberia and north-eastern Asia, based essentially on magic and sorcery. Their Heaven-God Ukko is but the chief among a host of nature-spirits capable of being influenced and even forced into obedience by the spells of *shamans* or sorcerers. 'The only trace of the influence of Buddhism,' says Max-Müller, 'among the Kadic races, the Finns, Lapps, &c., is found in the name of their priests, *Shaman* being supposed to be a corruption of *Sramana*, a name applied to Buddha and to Buddhist priests in general.' The Siberian Shaman works his cures by magic, and averts sickness and death by incantations. He works himself up into a frenzy of nervous excitement, beating loudly upon his magic drum, and doubtless is usually the dupe of his own powers. Nor is his superstition any less reasonable than that of the devout Protestant who opens his Bible expecting a divine answer in the first verse on which his eye shall fall; for the latter makes the same assumption that he can compel God to give him an answer, his own faith being the condition. See DIVINATION, MAGIC, and WITCHCRAFT.

Shammal, an eminent doctor of the Jewish law at the time of Herod, head of a most important

school, and supreme judge of the Sanhedrin during the presidency of Hillel (q.v.), along with whom he is, indeed, generally mentioned, and of whom he was, as it were, the complement. Very little is known of the history of his life; but he was probably born in Palestine, and he energetically participated in all the political and religious complications of the country. There was a rigidity in his character, which contrasts most strikingly with Hillel's proverbial patience. His religious views were strict, but his alleged 'harshness' is much exaggerated. His motto was 'receive all men with a cheerful countenance' (*Abot* i. 15). The discussions of the two rival schools, of which that of Shammai preponderated long after the master's death, turned all upon points of positive law.

Shamrock (Irish, *seamrog*), the national emblem of Ireland, a leaf with three leaflets, or plant having such leaves, sometimes supposed to be the Wood-sorrel (see OXALIDACEÆ), which unlike some of the rival claimants for the honour is certainly indigenous to Ireland. But the name is more frequently given to some species of Clover, or to some common plant of some of the nearly allied genera, as the Bird's-foot Trefoil (see BIRD'S-FOOT), or the Black Medick. It is not improbable that the name has a sort of general reference to plants with trifoliate leaves indigenous to Ireland; a perfectly satisfactory determination of the species is apparently as impossible as the attainment of botanical accuracy in regard to the emblematic thistle of Scotland. Lesser Yellow Trefoil (*Trifolium minus*) is the plant usually sold in Dublin on St Patrick's Day. The Common White Clover

Lesser Yellow Trefoil (*Trifolium minus*).

(q.v., *Trifolium repens*) has had a superstitious respect attached to it from early times, and is frequently treated as the Irish shamrock; though it is believed to have been but recently introduced into Ireland, where it is not so common as in England. According to the elder Pliny, no serpent will touch it; and the luck attached to the finding 'four-leaved clover'—a leaf with four leaflets instead of three (a not very uncommon monstrosity in clover, though very rare in wood-sorrel)—still causes many a futile search. The shamrock is said to have been first assumed as the badge of Ireland from the circumstance that St Patrick made use of it to illustrate the doctrine of the Trinity. But

the story is a late one, and is not found in any of the earlier lives of St Patrick; and so far as the theological argument is concerned, any plant with trifoliate leaves would answer the saint's purpose equally well.

Shamyl (ie Samuel), chief of the Lesghians and leader of the independent tribes in the Caucasus in their thirty years' struggle against all the might of Russia, was born at Aul-Hinry in northern Daghestan, became a priest or mollah, and was one of the foremost in the defence of Hinry against the Russians in 1831. In the end of 1834 he was elected 'Imam,' or head of the Lesghians, and soon made himself absolute temporal and spiritual chief of the tribes of Daghestan. He at the same time introduced a change of military tactics, abandoning open warfare for surprises, ambushes, &c, which brought numerous, and sometimes great, successes to the arms of the mountaineers. In 1839 the Russians succeeded in hemming Shamyl into Achulgo in Daghestan, took the fortress by storm, and put every one of the defenders to the sword in order to be quite certain that Shamyl should not escape. But by some mysterious means he did escape, and suddenly appeared preaching with more vigour than ever the 'holy war against the infidels.' Ten years later he again escaped from the same stronghold after the Russians had made themselves masters of it. During the Crimean war he was helped by the allies, who supplied him with money and arms; but after peace was signed the Russians resumed their attacks upon the Caucasian tribes with more energy, opened a road over the mountains, thus cutting off one portion of the patriots, and so compelled their submission. On April 12, 1859, Shamyl's chief stronghold, Weden, was taken after a seven weeks' siege, and his authority, except over a small band of personal followers, was wholly destroyed. For several months he was hunted from fastness to fastness, till at last (September 6, 1859) he was surprised on the plateau of Gounib, and after a desperate resistance, in which his 400 followers were reduced to 47, he was captured. He was assigned a residence at Kaluga in the middle of Russia, with a pension of £1000, and he died at Medina in Arabia in March 1871, having taken up his residence in Mecca the year previously. In faith he was a Sufi.

Shandy Hall. See STERNE.

Shanghai, one of the original treaty ports of China, is situated on the left bank of the Hwang-pu, 12 miles from its entrance into the estuary of the Yang-tsze-kiang. The native city, about a mile in diameter, surrounded by walls, with narrow and dirty streets, had at one time a considerable cotton industry, but its importance has been entirely overshadowed by the foreign settlements outside its walls. In accordance with the treaty of Nanking (1842), it was chosen by Britain as one of the five ports to be opened to foreign trade, and in 1843 the British settlement was founded to the north of the native town, with a frontage to the Hwang-pu of three-fifths of a mile, and bounded by the Soochow tributary of the Hwang-pu. The narrow space between the settlement and the native town was in 1849 acquired by the French, and in 1862 the Americans established themselves north of the Soochow. The parts adjoining the river have now all the aspects of a modern European town, with well-made and electric-lighted streets, tramways, imposing public and commercial establishments, churches (including an English cathedral by Sir Gilbert Scott), hospitals, schools, theatres, and newspaper-offices. There is a large native population in the western parts. The Chinese Maritime

Customs' estimate in 1922 gave the population at 1,500,000. The British and American settlements have a joint, and the French a separate, municipal government, but there are no restrictions as to residence. Foreigners are only subject to their own laws, and each of the treaty powers has a separate court administering its own laws, both in civil and criminal matters. Shanghai is the seat of St John's Missionary University, Nanyang Government University, and Harvard Medical College. Formerly extremely unhealthy, the place has improved vastly through the healthier conditions of the settlements. Shanghai is the most important of the treaty ports of China, and it has grown enormously since it was thrown open to foreign trade in 1842. A great trading port and dockyard, it is rapidly becoming also a great manufacturing centre, with textile industries, including cotton and silk factories, large modern flour-mills, &c. It is an important railway centre, and a wireless telegraph station. At Pa-tung, opposite the British settlement, there are extensive shipbuilding and engineering establishments.

The chief exports are silk, tea, raw cotton and yarn, beans, wool, hides, rice, and other cereals; the imports being cotton yarn, cotton and woollen manufactures, kerosene oil, sugar, metals, and coal.

In 1853-55 a party of T'ai-ping rebels held the native city for a year and a half; but the foreign settlements were secured from harm by the presence of a British squadron, and became a refuge for the Chinese from all parts of the province of Kiang-su, which the T'ai-pings continued to desolate up to 1862. In 1860-61 the rebels again attacked the city, but were repulsed, and finally driven out by the British and French forces. By agreement, Shanghai was exempted from war operations during the Sino-Japanese contest. In the political confusion after the Great War, Shanghai was the scene of many disturbances, some of which were directed against the Europeans. Britain sent a 'Shanghai Defence Force' in 1927.

Shanklin, a watering-place on the south-east coast of the Isle of Wight, 8 miles by rail S. of Ryde. Pop. (1921) 7374.

Shanks, EDWARD, was born at London in 1892 and educated at Merchant Taylors' and at Trinity College, Cambridge. He won the Hawthornden Prize for Imaginative Literature in 1919, and published several volumes of poetry brought together, with the exception of *The Queen of China* (1919), in his *Collected Poems* (1926), also two volumes of *Essays in Literature* (1923, 1926). His style is eminently lyrical, restrained, and tinged with a grave melancholy that tends towards suggestion rather than dramatic effect.

Shannon, the largest river of Ireland, rises in the Cuilcagh Mountains, County Cavan, and falls after a course of 254 miles into the Atlantic Ocean between Loop Head and Kerry Head. Flowing south-westwards, it soon reaches Lough Allen in Leitrim; thence it proceeds through a succession of expansions—Loughs Boderg, Bofin, Forbes, Ree, and Derg—past the towns of Carrick, Athlone, and Killaloe, to Limerick. There it departs from the southerly direction it has hitherto pursued and turns westwards, forming a wide estuary some 70 miles long and 10 miles across at its seaward extremity. About 10 miles from the entrance the river narrows to about 1½ mile in width. Outward navigation commences at Foynes, which is connected by railway with Limerick, and from which steamboats ply to Kilrush, Tarbert, and the intermediate stations. Vessels of 1000 tons can, however, get up to Limerick, and small steamers to Athlone; boats ascend the river to beyond Lough Allen. Several tributaries fall into the

Shannon, as the Suck and Fergus from the right, and the Inny, Brosna, Mulkear, Maigue, and Deel from the left. The main river is canalised for some distance below Athlone, and again between Killaloe and Limerick. This important system of navigation, which occupies a position almost midway between the east and west coasts of Ireland, is connected with Dublin by means of the Grand and Royal Canals.

Shannon, CHARLES, came into prominence as a portrait and figure painter about 1897, and in 1921 was elected R.A. His style refers back to that of the old Italian masters; he indulges in transparent pigments instead of opaque direct painting; and, further, even in literary subjects and portraiture, lays great importance also on producing decorative patterns of colour and line.

Shannon, SIR JAMES JEBUSA (1862-1923), an accomplished portrait-painter, was born of Irish parents in New York State, but studied at South Kensington Art School (1878-81). Thereafter, for some forty years, he produced an average of ten portraits a year, full of grace and charm. He was made R.A. in 1909, and knighted in 1922.

Shanny. See **BLENNY**.

Shans, a number of tribes of common origin, who live on the borders of Burma, Siam, Laos, and China. They are the descendants of an aboriginal race of China; their home generations ago was in the mountainous region on the borders of the Chinese provinces of Sze-chuen and Shensi. In the course of time they have been pushed southwards. They seem to have entered the valley of the Irawadi in the 6th century B.C. The Shans and the Laos are one and the same people, and both are closely akin to the Siamese. The country the Shans inhabit may be broadly described as a succession of wide river-valleys (of the Menam, Meping, Mekok, Mekhong, &c.) separated by high ridges; on the north it climbs up to the Yunnan plateau of southern China. There are extensive and valuable forests of teak; iron, rubies, and silver are extracted; and gold, copper, coal, and petroleum are known to exist. Rice, cotton, and tobacco are the crops most extensively grown. The people are noted for chased work in gold and silver. They are distributed amongst several states, of which the most important are Zimmé (Chieng-Mai), Kiang Hsen, Lapon, Nan, Lakhon, and Peh, tributary to Siam; Luang-Prabang, now French; Kiang Hung, Kiang Tung, Mone, Katchin, and others now incorporated in Burma. The Shans are an indolent, laughter-loving people, fond of gambling and cock-fighting, not unwarlike, though orderly and fairly trustworthy; the women have great influence, and enjoy equal freedom with the men. Slavery, however, exists, but in a mild form; and serfdom is general. The rule of the native chiefs is generally just and mild, and taxation is light. Buddhism is the dominant religion, though it is mingled with many superstitious practices. Zimmé and others of the principal towns are the seats of a very extensive transit trade between Yunnan, Tali, and the marts of southern China on the one side, and Bangkok and the ports of Burma on the other. There is also a large trade in the native commodities—horns and hides, ivory, cutch, gold-leaf, saltpetre, sapan wood, salt, lead, steel, betel-nuts, stick-lac, &c. A railway from Mandalay towards the Chinese border traverses the northern Shan states. The famous Golkeik viaduct (2260 feet long) carries it over the gorge of the Chunzoune River. Its steel trestle work rests on a remarkable natural bridge of limestone, 500 feet above the level of the water.

The first Shan state to reach historical importance was the Mau kingdom, the ruler of which in

the 13th century conquered all Burma, the upper part of Siam and the Malay Peninsula, and made his influence felt from Tali in China as far as Java and Cambodia. All the northern portions of this extensive empire, including Burma, were ruled by Mau princes down to 1554. Shortly after that date the tables were turned, and most of the Shan states became tributary to the emperor of Pegu. Other powerful states about the same period were Zimmé and Vien-chang. The former still exists, but subject to Siam; the latter, a Laos state, was destroyed in the 18th century. About 1774-77 Siam drove out the Burmese and Peguans, and made herself mistress of the southern Shan states, Zimmé and Vien-chang. Ruins of large cities exist in great numbers throughout the middle portions of the Shan country, relics of the ephemeral capitals of different Shan states.

See books by Hallett (1890), Colquhoun (1885), Cheek, Carl Bock (1884), Mrs Milne (1910); E. Aynonier in the *Revue de l'Histoire des Religions*, 1891; Nisbet, *Burmah under British Rule* (1901); R. le May, *An Asian Arcady* (1926); and books quoted under SIAM.

Shan-si, a province of northern China, having the Hoang-ho on its western boundary. The southern part is a high plateau; the northern is occupied by great mountain-ranges, 10,000 or 12,000 feet high, dotted with Buddhist temples. The south is one of the richest coal and iron districts in the world. Salt and other minerals are also got. Communications, however, are bad. There is not much agriculture, though some parts are very fertile. Area, 80,000 sq. m.; pop. 10,000,000; capital, Tai-yuen Fu.

Shan-tung, a maritime province of north China, consists of an alluvial plain in the west, formed by the Hoang-ho delta, and a mountainous region in the east, running out in the great peninsula which, with the Liao-tung peninsula opposite, encloses the Gulf of Chih-li. Products are coal, iron, wheat and other cereals, fruits, silk, and wax. Area, 56,000 sq. m.; pop. 26,000,000; capital, Chih-nan Fu. On the coast are Wei-hai-wei (q.v.) and Kiao-chau (q.v.). The Great War gave Japan an opportunity of getting a footing in Shan-tung. By the treaty of Versailles Kiao-chau and all German rights over railways, &c., were transferred to Japan, and disputes over the question of their restoration to China continued till 1922.

Shari, the principal feeder of Lake Tsad (q.v.).

Shark, a common name for most of the Elasmobranch fishes included in the sub-order Selachioidei. They are voracious fishes, with two or three exceptions carnivorous, the smaller forms often eating crustaceans and molluscs, as well as fishes, to which the larger forms almost exclusively restrict themselves. They sometimes attack men who swim incautiously in warm seas. Unlike the flattened rays, the sharks usually preserve the typical fish-like form, and the gill-slits are lateral, not ventral. In most the skin is covered with minute thickly-set skin-teeth, really like those of thornbacks, but much smaller and more numerous. The teeth on the jaws are very sharp, generally triangular, and are disposed in rows. In most cases only the row on the ridge of the jaw is in use, but as this is worn away it is replaced by the next row, which is gradually moved forward. Some of the sharks are viviparous, others are oviparous. In the latter each egg is enclosed in a horny 'mermaid's purse.'

As to their distribution, sharks, though most

numerous in the tropics, are represented in almost all seas, and many venture up estuaries and rivers. One species occurs in Lake Nicaragua. Many live in the open sea, and voyagers know how they follow the ships, hungrily swallowing—with little discrimination—what refuse is thrown overboard. Though few are like the Portuguese Shark (*Centroscyllium callolepis*) in living in deep water, not a few live a sluggish existence at the bottom of relatively shallow water near the shore. Many of the smaller forms are gregarious, and prey upon the shoals of herring and mackerel.

The classification of sharks has not yet been

White Shark (*Carcharias vulgaris*).

placed on a thoroughly firm basis. Gunther recognises the following families. Carchariidae include the genus *Carcharias*, of which the Blue Shark (*Carcharias glaucus*), 12-15 feet in length, and the larger White Shark (*C. vulgaris*) are representative; the genus *Galeocerdo*, with several formidable species; the genus *Galeus*, of which the Tope (*Galeus canis*) occurs on British coasts; the genus *Zygæna*, notable for the large transverse eye-bearing lobes of the snout to which these voracious fishes owe their name Hammer-head (q.v.); the genus *Mustelus*, with small species known as 'Hounds.' In *Mustelus laevis* and *Carcharias glaucus* there is a peculiar placenta-like connection between the mother-fish and the yolk-sac of the unborn young.

Lamnidae include numerous large pelagic sharks, such as the Porbeagle (*Oxyrhina cornubica*), which frequents the North Atlantic, attains a length of 10 feet, and is said to swallow its prey whole; the Man-eater Shark (*Carcharodon rondeletii*), in all tropical and temperate seas, attaining a length of 36 feet; the Fox-shark or Thresher (*Alopias vulpes*), not uncommon around British coasts, attaining a length of 13 feet, notable for the enormously elongated upper lobe of its tail, and for its voracious attacks on herring and mackerel; the Basking-shark (*Selache maxima*), attaining a length of 30 feet, living on small fishes, often in the habit of lying passive, and like the thresher harmless to man unless attacked. The *Challenger* explorers dredged numerous large teeth belonging to some shark of the genus *Carcharodon*; as these measured 5 inches along the side and 4 across the base, there must be some larger species than *Carcharodon rondeletii* either still alive or not long since extinct.

Notidanidae form a small family including a few tropical or subtropical sharks, sometimes called cow-sharks, and referable to the genus *Notidanus*, from which, however, some distinguish two other genera, *Hexanchus* with six gill-slits, and *Heptanchus* with seven.

Scylliidae form a family of small sharks, usually called dog-fishes, including *Scyllium canicolum* and *S. catulus*, the common dog-fishes of British shores; *Stegostoma tigrinum*, a beautiful striped shark frequenting the Indian Ocean; and the Indo-Pacific ground-shark (*Crossorhinus*), which lurks on the bottom, and is protectively coloured.

Cestraciontidae, a family now somewhat decadent, twenty-two of the twenty-five genera being extinct. The living forms—e.g. *Cestracion* or *Heterodontus galeatus*—are called Port Jackson sharks. The front teeth are small and sharp, those behind are flat and arranged in pavement-like rows.

Spinaciidae form a family including the small spiny dog-fishes—e.g. *Acanthias vulgaris* and *A. blainvillii* on British coasts; the voracious Greenland Shark (*Laemargus borealis*), which attains a length of about 15 feet; the Black Dog-fish (*Centroscyllium fabricii*) of Arctic seas; *Centroscymnus coelolepis*, which is caught off the coasts of Portugal from a depth of 400–500 fathoms; the Spinous Shark (*Echinorhinus spinosus*), a Mediterranean form, which seems also to live in deep water.

Rhinidae form a family represented solely by the almost cosmopolitan, somewhat ray-like, Angel-fish or Monk-fish (*Rhina squatina*).

Pristiophoridae form a family parallel to the Pristiuridae among the rays, for the genus *Pristiophorus* has its snout prolonged into a saw as in the much larger genus *Pristis*.

It seems necessary furthermore to establish a family for a remarkable Japanese shark, *Chlamydoselachus anguineus*, a somewhat eel-like animal, 6 feet long, less than 4 inches in diameter, suggestive of a sea-serpent, but more important since it seems as if it were a direct descendant of forms which flourished in Devonian times (see FISHES).

Sharks are destructive to food-fishes and to fishermen's nets, and sometimes attack man himself. On the other hand, many of the smaller forms are eaten by man; the gristly fin-rays are used in China in the making of gelatine; the livers are sometimes utilised as sources of oil; the skin of those which are thickly beset with skin-teeth was formerly much used by cabinet-makers for polishing purposes, serving, under the name of shagreen, instead of sandpaper.

Sharon, the name of an extensive tract of plain and corn-land (partly under cultivation) in Palestine, lying between the sand-dunes of the coast and the foot-hills of the interior, and extending from the neighbourhood of Carmel on the north to near Joppa. The so-called Rose of Sharon is the subject of an article.

Sharon, a borough of Pennsylvania, on the Shenango River, 71 miles by rail NNW. of Pittsburgh. Its manufactories include rolling-mills and foundries, steel and boiler works, a chain-factory, planing and flour mills, a soap-factory, and machine-shops; and coal is largely mined near by. Pop. (1920) 21,747.

Sharp, a sign \sharp in Music, which, when prefixed to a note, elevates it by a semitone in the scale; see MUSIC. A double sharp \times raises a note another semitone.

Sharp, ABRAHAM, a meritorious mechanist and astronomer, who, born at Little Horton near Bradford in 1653, and apprenticed to a tradesman, became a schoolmaster, and acquired a thorough knowledge of mathematics and the cognate sciences. He also acted as exciseman and bookkeeper in a London office. In 1684–91 he assisted Flamsteed at Greenwich Royal Observatory. There he did admirable work on the instruments, perfecting hand-graduation and other processes, and making many very valuable observations; and after retiring to Horton (1694), he continued to assist Flamsteed by his extraordinary powers as a calculator. He published tables of logarithms and a treatise, *Geometry Improved* (1717), and made observations in a small observatory fitted up by himself. He died 18th July 1742. See his *Life and Correspondence*, edited by Cudworth (1889).

Sharp, CECIL (1859–1924), folk-song collector, was born in London, and educated at Uppingham and Clare College, Cambridge. In 1883 he was appointed Associate to the Chief Justice of South Australia, and at Adelaide founded a school of music. In 1893 he became Principal of the Hampstead Conservatoire, in 1911 founded the English Folk Dance Society, and later visited the Appalachian Mountains to collect older forms of the English folk-songs. He published many volumes of English folk-music (songs, morris dances, &c.), which influenced strongly the work of Bax, Delius, Holst, Vaughan-Williams, and other contemporary English composers.

Sharp, GRANVILLE, abolitionist, was the son of the archdeacon of Northumberland, and was born at Durham in 1735. He came to London, and, after studying law, obtained a post in the Ordnance Office; but this he resigned in 1776 on the outbreak of the war with America, of which he disapproved. He was the author of upwards of sixty-one publications—mainly pamphlets—on philological, legal, political, and theological subjects (the English tongue, hundreds and titlings, the definite article in the Greek Testament, Hebrew syntax and pronunciation, Melchisedek, Armageddon); but his principal writings and the main labours of his life were in defence of the negro, and for the abolition of the slave-trade and slavery. He defended the cause of the negro Somerset, securing the decision of the twelve judges (1772) that as soon as a slave touches English soil he becomes free. He was with Clarkson one of the founders of the Association for the Abolition of Negro Slavery, and assisted in the establishment of the colony of Sierra Leone for freedmen. He died in London, 6th July 1813. There is a *Life* by Hoare (1820), and a smaller one by Stuart (New York, 1836). See also SLAVERY.

Sharp, JAMES, Archbishop of St Andrews, was born at the castle of Banff on 4th May 1618, the son of the sheriff-clerk of Banffshire. Educated for the church at King's College, Aberdeen (1633–37), he afterwards visited England, and became acquainted with several eminent English divines, as Hammond, Sanderson, and Taylor. In 1643 he was appointed a 'regent' of philosophy at St Andrews, and in 1648 minister of Crail, an office which he held throughout Cromwell's ascendancy. In 1651, however, when Monk was reducing Scotland to obedience, Sharp was carried off to England with several other ministers; but he quickly regained his liberty, and for some years enjoyed the confidence of the 'Resolutioners,' or more moderate party in the church. In 1656 he was chosen by them to plead their cause in London before the Protector against the 'Protesters;' and Baillie speaks of him on this occasion as 'that very worthy, pious, wise, and diligent young man.' On the eve of the Restoration he was sent up again to London to use his utmost endeavours with Monk in favour of the Kirk of Scotland, and at Monk's suggestion he crossed over to Breda, and had several interviews with Charles II. His correspondence for some months after his return from Holland is full of apprehensions of Prelacy, 'cassock-men,' and the Service-book; but its perfidy stands revealed in his letter of 21st May 1661 to Middleton, which proves that he was then (as probably before) in confidential communication and hearty co-operation with Clarendon and the English bishops for the immediate re-establishment of Episcopacy in Scotland. The bribe was a great one, for on 16th December he was consecrated Archbishop of St Andrews, having first received Episcopal re-ordination. The supple and dexterous tool of Middleton or Lauderdale, as either gained the ascendancy, a liar and coward, and a vindictive oppressor of

those he had betrayed, he soon became an object of detestation to the populace and of contempt to his employers. When in 1668 Robert Mitchell, a conventicle preacher, fired a pistol at him in the streets of Edinburgh, the bystanders suffered the fanatic to escape—only, however, to be executed ten years later on his own confession, enticed from him by an assurance of his life. At last, on 3d May 1679, on Magus Muir, twelve Fife Covenanters—Hackston of Rathillet, John Balfour of Kinloch, the rest peasants or artisans—fell in with him as he was driving with his daughter to St Andrews, and, dragging him from his coach, hacked him clumsily to death in spite of his frantic prayers. Even his apologists can plead little for him but that he was not licentious, that his portrait is not that of a monster of cruelty, and that he was simply an ambitious ecclesiastic of plausible and courtly manners, who may have thought that, if there must be an archbishop of St Andrews, there was no great reason why he should not be the man.

See his *Life and Times* by Stephen (1839); Hill Burton's *History of Scotland*; O. Airy's *Lauderdale Papers* (Camden Soc. 1884).

Sharp, WILLIAM (1749–1824), a London engraver and republican; see *Life* by Baker (1875).

Sharp, WILLIAM (1855–1905), poet and essayist, critic, and romance-writer, partly Lowland Scottish, partly Swedish, by descent, was born at Paisley, settled in London 1879, and published *Earth's Voices*, *Sospiri di Roma*, *Sospiri d'Italia*, and other volumes of verse, half-a-dozen novels, and books on Rossetti, Shelley, Heine, Sainte Beuve, Philip Bourke Marston, besides many miscellaneous essays and studies in literature and criticism. But he will chiefly be remembered as the author of the remarkable series of Celtic tales and romances 'by Fiona Macleod' which began in 1894 with *Pharais, a Romance of the Isles*. As 'Fiona Macleod' Sharp found his themes in the Celtic myths of early Ireland and Scotland, and so treated them as to become one of the chief representatives of that 'Celtic Revival' of which Mr W. B. Yeats was the protagonist. 'The beauty of the world, the pathos of life, the gloom, the fatalism, the spiritual glamour—it is out of these, the spiritual inheritance of the Gael, that I have fashioned these tales.' *From the Hills of Dream* is a collection of lyrics; *Through the Ivory Gates*, poems; *The Immortal Hour*, a drama based on a Celtic legend and set to music by Rutland Boughton. Sharp continued till his death to maintain the secret of his pseudonym.

See the *Memoir* (1910) by his wife, who arranged an edition of *The Works of Fiona Macleod* in 7 vols. (1910).

Sharpe, CHARLES KIRKPATRICK (1781–1851), was born at Hoddam Castle, Dumfriesshire; studied at Christ Church, Oxford; and in 1813 fixed his bachelor home in Edinburgh. A clever versifier and a clever draughtsman, he wrote for the *Anti-Jacobin*, edited club-books, but is chiefly remembered by his immense correspondence.

See the *Memoirs* prefixed to the *Letters* (2 vols. 1888) and to his *Etchings and Prose Fragments* (1869).

Sharpe, SAMUEL (1799–1881), a descendant of Philip Henry and nephew of Rogers the poet, in whose bank he worked till sixty, wrote on Egyptology and, from the Unitarian standpoint, on biblical subjects. See *Life* by Clayden (1883).

Shatt-al-Arab. See EUPHRATES.

Shaw, GEORGE BERNARD, an original, brilliant, and (latterly) eminently popular dramatic writer, Fabian Socialist, and unconventional critic of things in general, was born at Dublin in 1856. Privately educated, he came in 1876 to London, and there embarked, at first with small success, in a career of

journalism and literary work. Between 1880 and 1883 he produced four novels, the best known of which is *Cashel Byron's Profession*, with a boxer for hero. In 1883 he became a Socialist agitator, and helped to form the programme of the Fabian Society, editing the essays of the League, to which he had contributed, in 1889. Several tracts from his pen were also published by the same adventure, among them *The Quintessence of Ibsenism* in 1891 (completed to Ibsen's death, 1913). In 1892 appeared the first of his clever and eccentric plays, *Widowers' Houses*, produced by the Independent Theatre Society, and followed by *Arms and the Man* (1894), *Candida*, *The Man of Destiny*, and *The Admirable Bashville* (from *Cashel Byron*). *Man and Superman* (1903), with its long dream-interlude of Don Juan, whatever may be the fate of its philosophy of the 'life-force,' contends for truth against sentimentalism. *John Bull's Other Island* (1904), a study of the Irish question, was published along with *Major Barbara* and *How He Lied to Her Husband*, a parody of his own *Candida*. Seven of his plays were published as *Plays Pleasant and Unpleasant* (1898), and three as *Plays for Puritans*. *Mrs Warren's Profession*, one of the so-called unpleasant plays (plays arising out of facts that the sentimentalist prefers to be blind to), was condemned by the Censor, and was not acted until the Stage Society produced it in 1902, while public performance in Great Britain was not allowed till 1923. The same difficulty with *The Shewing up of Blanco Posnet* (1909) was got over by producing it in Dublin. Later collections are headed by *The Doctor's Dilemma* (1906), *Misalliance* (1914), *Androcles and the Lion* (1916), and *Heartbreak House* (1919). *Fanny's First Play* won over many by its geniality, *Pygmalion* by a verbal audacity. *Back to Methuselah* (1921) is a philosophical pentalogy, but *Saint Joan* (1923) is generally accounted his masterpiece. The plays are more didactic and philosophical than artistic, though Mr Shaw is a master of dialogue and of English prose. They are full of an exuberant, satirical, paradoxical, iconoclastic, and tantalisingly elusive humour, and so far depart from dramatic form that the stage directions are essays, and *Misalliance* is frankly described as 'a debate in one sitting.' He owes much to Ibsen, but perhaps more to the later Samuel Butler. Besides plays, novels, and political and social tracts, he wrote books of musical and dramatic criticism and aesthetics (*The Perfect Wagnerite*, 1898, &c.).

See books on him by G. K. Chesterton (1909), McCabe (1914), and Collis (1925), and his own introductions.

Shaw, JACK, Life-guardsman. See PUGILISM.

Shawl. Kashmir shawls are made of a very fine material called *pashm* or *pashmina*, consisting of the inner or under wool of the shawl-goat of Tibet (see KASHMIR GOAT). This wool is separated with much care from the longer hair of the animal, and is then cleaned and spun with great delicacy into a fine thread. The dyeing of the yarn is a very important and difficult operation, almost all the colours from native dyes being permanent.

In the case of those shawls which have their patterns produced by needlework or embroidery the ground consists of a plain pashmina fabric, and the thread used for the pattern is of the same material. The shawls with loom-woven patterns, notwithstanding their intricate nature, are made on very rude and primitive looms. Three or sometimes four weavers are engaged at one of these looms, and instead of using shuttles they work with numerous wooden needles (each being supplied with coloured yarn), which have slightly charred ends, but no eyes. The shawls are woven face downwards, and the work is carried on at the

back or reverse side, on which the needles hang in rows. After the threads are worked in to suit the pattern across one line of weft, they are knotted to the warp and driven firmly into their place by the reed or comb. On an average five shawls are produced on one loom in a year, but a loom may be occupied during this period with only one shawl if it is of very fine quality and of an elaborate pattern. A shawl is, however, often woven in separate pieces, and so neatly joined together that it looks as if it had been woven in one piece.

Inferior shawls are manufactured in the Punjab by artisans who at various times have emigrated from Kashmir. They are woven at Amritsar, Ludhiana, Jalalpur, Narpur, and a few other places. For these the fine pashm is mixed with another kind of goat's wool called *kook* from Kerman in Persia. Shawls somewhat resembling those of Kashmir, though much less costly, are largely manufactured at Kerman itself, the *kook* of which they are made being, like the pashm from the Tibetan goat, the under-wool of the animal. But the most beautiful shawls woven in Persia are made of silk, and these too are like fine Kashmir shawls in general appearance. Both in India and in Persia shawl-cloth is made into tunics and other shaped articles of dress for men and women.

The production of shawls was formerly an important branch of manufacture in France, and gave occupation to a large number of designers in Paris, who furnished designs not only for those woven in their own country—chiefly at Paris, Lyons, and Nîmes—but also for shawl-manufacturers in England and Austria, and even for some in Kashmir. Shawls of various kinds are made at different places in England, and in past years many of these were designed in the Indian style. At Paisley, in Scotland, shawl-weaving was a staple industry from 1800 to 1860. Silk, cotton, and woollen yarns were selected, and used separately or in combination; but the best-known class of Paisley productions consisted of fine wool, with the patterns in the style of those woven in Kashmir. As many as 8000 hand-loomers are said at one time to have been engaged in the Paisley district on these goods. Soon after the middle of the century the trade, however, began to decline, and has not been since revived. Modern shawls are of a simpler variety, and are produced in the medium thicknesses of woollen and worsted yarns. They include wraps, warm neckwear, and rugs. Tartan checkings and twilled patterns in mingled colourings are chiefly applied, decorative schemes of design being neglected. In these forms they make a standard class of manufacture, more especially in the tweed centres of Scotland and Ireland, the travelling rugs and modes being single or compound in structure and either loosely or compactly woven. Many variations are made in the type and quality of the fabric. Thus in the heavier grade of travelling rugs and shawls, one surface may be composed of worsted yarns and 'clear' finished, and the second surface in woollen yarns and 'fibrous' or 'fleece' finished; while in the ordinary grades, in which both surfaces coincide in textural features, newness and freshness of manufactured product are acquired by the methods of blending tinted materials in the processes of yarn-spinning. Knitted shawls and wraps also give a useful branch of fabrication.

Though changes in fashion have eliminated the Eastern scheme of design from modern shawl manufacture, it is to be regarded as a pure and distinctive style of woven decoration. As such it is, from time to time, elaborated in the weaving of silk scarves, handkerchiefs, and the like, and in the origination of ornamental textiles. The most characteristic feature in a typical design is

what has been usually called the 'cone' or 'pine cone,' of which a few varieties are shown in the annexed figures. It appears, however, to be really a conventional representation of a wind-bent cypress-tree, as the term *sarv*, the native name of that tree, is also applied to this pattern or part of a pattern. The form has many modifications, one or more of which often make up the groundwork of the designs of other textile fabrics both in India and Persia, and it even appears on metal-work and papier-mâché made in Kashmir. Sometimes it is simply called the shawl pattern. It is, however, not merely the graceful outline of their ornamental devices, but also the harmonious blending of their deep-toned colours, which gives a singular charm to these exquisite productions of Eastern looms.

Shawnees, a tribe of American Indians of the Algonquin family, formerly settled mainly in New York, Pennsylvania, and Ohio, but driven westward by the Iroquois. They helped the French against the English, gave trouble to the newly-founded United States, and in 1812 some bands joined the English. They afterwards removed to Missouri, Kansas, and Indian Territory (Oklahoma).

Shea Butter. See BUTTER-TREE.

Shea Oak, or SHE OAK. See CASUARINA.

Shearwater (*Puffinus*), a genus of pelagic birds represented in all the oceans, nearly related to petrels. The name refers to the habit of skimming close to the waves. Shearwaters feed on fishes, cuttlefishes, and other open sea animals, often dashing down upon them with considerable force and disappearing for the moment. Most are sooty-brown or grayish above, and white below; the wings are long and pointed; the feet are webbed, with a rudimentary hind-toe; the nostrils are tubular and open separately; the strong bill is slightly hooked. The nest is a mass of grass and rubbish in a burrow in a bank, or in a hole among rocks. The fishermen of the Canary and Salvage Islands anticipate the needs of the birds by making little stone huts for them. A single whitish egg is laid, which both parents incubate for a prolonged

The Manx Shearwater (*Puffinus anglorum*).

period. The Manx Shearwater (*P. anglorum*), 15 inches long, is widely distributed in British waters, and nests in retired places, especially turf

islands and shelved cliffs. It is the 'Lyrie' of the Orkneys and Shetlands, the Fachach of other parts, and is often eaten. It vomits a greenish oil when captured. It is a shy bird, usually nocturnal or crepuscular; its note is *cuck-cuck-ōō*, generally thrice repeated. Nearly related is the Levantine Shearwater (*P. yelkouanus*), the well-known *ame damnée* of the Bosphorus. The Great Shearwater (*P. gravis*), the 'Hagdown' of fishermen, 19 inches long, often approaches British shores, and is common on the Atlantic. It is an expert diver. The only known nesting-place is Tristan da Cunha in the South Atlantic. Another species, occasionally visiting Britain, is the Sooty Shearwater (*P. griseus*); it nests in the southern hemisphere—e.g. on the Chatham Islands. A great rarity for Britain is the Little Dusky Shearwater (*P. obscurus*) from Madeira and Cape Verde.

Shebeen (Irish), a term in use, especially in Ireland and Scotland, for a house where intoxicating liquors (usually whisky) are sold without a licence. See LICENSING LAWS.

Sheboygan, a port, capital of Sheboygan county, Wisconsin, on Lake Michigan, at the mouth of the Sheboygan River, 53 miles by rail N. of Milwaukee. It has a good harbour, and contains foundries, tanneries, and planing-mills, manufactures shoes, chairs, toys, &c., and has a lake-trade in agricultural products. Pop. 31,000.

Shechem. See NABLUS.

Shechinah. See ARK OF THE COVENANT.

Shee, SIR MARTIN ARCHER, portrait-painter, was born at Dublin, 20th December 1769, studied drawing, and as a boy of sixteen became famous as a portrait-painter. In 1788 he settled in London, where he became A.R.A. in 1798, R.A. in 1800, and President of the Royal Academy in 1830, when he was knighted. He was regarded as a rival of Lawrence, though his art was but poor and few of his portraits are now thought much of. He wrote several poems, didactic, tragic, and other; a novel; and a *Plan for the Encouragement of Historical Painting*. He died at Brighton, 19th August 1850. See the Life by his son (2 vols. 1860).

Sheeahs. See SHITES.

Sheen. See RICHMOND.

Sheep (*Ovis*), a genus of ruminant quadrupeds of the family Capridæ, so nearly allied to goats that the propriety of generic distinction is very doubtful. They differ from goats in having the outline of the face more or less arched and convex; the horns spiral, sometimes very large in the males—in domestication, however, wanting in many breeds; the chin destitute of a beard; a sac or pit between the toes of each foot, lined with hair, and secreting a fatty matter. Upper incisors and canine teeth are wholly wanting: see BOVIDÆ, CAPRIDÆ. It is supposed by some that all the wild sheep existing in different parts of the world are mere varieties of one species; and it is impossible to say from which of the wild species the domestic sheep is sprung.

All the wild sheep known are natives either of mountainous regions or of dry and elevated tablelands. They are gregarious, a character which the domesticated sheep fully retains. They are generally seen in small flocks, and are not easily approached, taking refuge in flight, a sharp whistling sound emitted by one of the rams serving as an alarm to the whole flock; although they are very capable of making a vigorous defence when driven

to close combat. A ram of the domestic species is indeed able to sustain a conflict with a bull, taking advantage of his far greater agility, and butting against his foe with his strongly armed forehead. A ram has been known to throw a bull on the ground at the first onset, and is always ready to defend himself and his companions against a dog. Many rams exhibit great pugnacity. Sheep differ from goats in their mode of fighting; goats rear themselves on their hind-legs, and throw themselves sideways on their adversary, to bring the points of their horns to bear; whereas sheep rush straight at each other, a mode which better suits the different style of armature of the head. Rams of the black-faced variety are especially powerful with their heads, and often at the rutting season kill each other. Their naturally strong skull is further protected in battle by heavy arched horns. A thorough ram fight is a terrifying sight. The two warriors go backwards each some fifteen or twenty yards, and then meet each other with great violence, their heads cracking loudly, and their beam-ends rising in response to the collision of heads. Ewes of this breed fight also. Sheep without horns are not usually so pugnacious as the mountain breeds.

All the wild sheep have short wool, with an outer clothing of long and nearly straight hair. But even the long hair has usually the peculiar character of wool, in that roughness of surface which gives it the property of *felting* (see HAIR, WOOL, FELT). One effect of domestication in the common sheep has been to cause the disappearance of the outer long hair, and to produce instead an increase of the length and abundance of the wool, an object of great importance to the sheep-farmer. In neglected breeds of the common sheep the two kinds of hair or wool are very apparent. In some tropical climates the sheep loses its abundant fleece, and is covered with hair little longer than that of the ox.

Although not equal to goats in their adaptation to rocky steeps, and not endowed with such power of leaping from crag to crag, most breeds of sheep exhibit a strong disposition to seek their food in places where no animal not very agile and sure-footed could venture; and those of the domesticated breeds which retain much of their original wildness are thus adapted to situations in which otherwise the pasture would be of little value to man. In fine weather sheep ascend the heights, and in cold and stormy weather they repair to the lower grounds. In modern times it has been customary to remove the large flocks from mountainous regions to lower grounds to pass the winter; and in the fall of the year shepherds have difficulty in preventing the animals from leaving the summer pastures too early if the weather is unfavourable. On the other hand, if fine spring weather sets in before the period of removal from the winter-quarters, the flocks keep pressing towards the summering regions. Mountain sheep have favoured spots whither they go regularly over-night, and the ewes generally have choice localities to which they go to lamb. They get much attached to certain pastures, and many of them have been known to return stealthily, in the course of a few days, to their native or appreciated pastures, though removed many miles.

A very interesting wild sheep is the Great Mountain Sheep (*Ovis poli*) on the Thian Shan and other lofty chains of central Asia: 10½ hands high, the horns (each some 3 feet long) forming a wide open curve. It was met with by Marco Polo (hence the name). The Argali (*O. ammon*), found east and north of it, is the subject of a separate article. The Moufflon (*O. musimon*) is the wild sheep of the mountains of Corsica and Sardinia, and an allied form inhabits Cyprus and parts of Asia Minor. The Rocky Mountain Sheep, or Big-

horn (*O. montana*), of North America, is as big as the Aigali, which it much resembles also in general appearance. The flesh is of the very finest quality. The wool is very fine, fully an inch and a half long, and completely concealed by long hairs. The general colour is brown, paler on the lower parts; the old rams are almost white in spring. The Big-horn is found from Nebraska to the Pacific coast-ranges, and from the Rio Grande northward to 68°, and occurs in herds of from three to twenty or thirty. The Aoudad, or Barbary Sheep (*O. tragelaphus*), a native of the north of Africa, inhabiting chiefly the lofty parts of the Atlas Mountains, has the throat, chest, and front of the forelegs adorned with long shaggy hair.

The Common Sheep (*O. aries*) was probably the first animal domesticated by man; Abel, the 'keeper of sheep,' brought an offering unto the Lord 'of the fistlings of his flock and of the fat thereof;' and lambs were amongst the most frequent sacrificial offerings of the Jews. The felting and weaving of wool were unquestionably among the earliest of the arts. The wool was probably at first pulled from the skin, a cruel practice which long survived in some places. Sheep-shearing is often referred to in Scripture. The leather made of the skin of the sheep is much employed in book-binding, and for making gloves. In patriarchal times the milk was much used, as it still is in some countries; it is richer than cow's milk, and the cheese made of it has a sharp taste and strong flavour, which, however, are greatly relished by some. In some mountainous parts of India the sheep is even used as a beast of burden, carrying loads of from 35 to 40 lb. up steep crags, where almost no other animal could be employed.

Those who watch sheep carefully, or keep them as pets, find them by no means devoid of intelligence. They have, however, a stupid habit of following, without scruple, the leader of the flock; so that, when sheep are being driven across a narrow bridge, or where a fence separates the road from a precipice, if anything occur to deter them from proceeding in the proper path, and one break over the fence or parapet, more of the flock may be expected to follow, as has sometimes happened, to their utter destruction. Sheep very soon come to know the voice of the shepherd, and also the appearance as well as the bark of the shepherd's dog. Though they stand more in awe of the shepherd's voice or commands than of any other human being's, the dogs that regularly move amongst them fail to keep them in such subjection as strange ones do.

The 'rutting' is from September till the middle of December, according to the variety of sheep and the system of feeding. White-faced modern breeds have the tups early among them, and the hill flocks are later. The period of gestation is about 21 weeks. Ewes occupying sown or low-ground pastures lamb in January, February, and March, while those not so well provided for—the mountain sheep—do not drop their lambs usually till April. The ancient breeds generally have only one lamb in a season, but modern highly-fed varieties frequently have twins, occasionally triplets, but rarely more. There is at least one variety in England, the Dorset Horn breed, which produces two crops of lambs each year. Lambs intended to come early into the market are as often as possible dropped in January. Generally lambs are weaned in July and August. Weaning of breeding or store lambs, however, is a feature of modern sheep-farming; at one time it was not uncommon to see several generations persistently following the parent stem. The shearing season ranges from the 1st of May till the middle of July, according to the description of sheep, the nature of the feeding, &c. Dipping, or immersion

in an insecticidal solution, is usually done a few weeks after clipping, and again in autumn. In Britain it is compulsory to dip twice a year.

The great object for which the ancient Britons possessed sheep before the Roman invasion was the production of wool. The demand for meat has now raised the value of mutton and lamb so much, that the farmer finds it profitable to devote much of his attention to supplying the market with these articles; and those breeds of sheep are reckoned most valuable which are most suitable for this purpose, even although the crop of the wool is inferior. When there was no food for sheep but the natural pasture, the animals could not be fattened for the market except during summer, and not until they had attained an age of three, four, or five years; whereas most of the mutton now consumed is the flesh of sheep not more than eighteen months old, fattening being aided by turnips, man-gold, other green food, oilcake, and grain.

The young branches of heath, and in lower situations the shoots of furze, often serve as food for sheep, when the supply of grass fails. Sheep delight in the short grass and peculiar herbage of hill pastures and bare downs; and the mutton produced in such pastures, and by the breeds most suitable to them, is of superior quality to that of the large fat sheep fed on richer soils. The latter are also more liable to many diseases, particularly where the ground is at all moist. Aromatic and bitter herbs are particularly relished by sheep.

The breeds of sheep are very numerous, and very different.—The Black-faced Sheep of the Highlands of Scotland and of the north of England is perhaps as near the original type as any existing breed. Both male and female have horns; those of the ram large, with two or more spiral twists, those of the ewe much smaller, and little twisted. The face and legs are not always black. Many are speckled, and some principally white. The black-faced sheep is robust, very active, and hardy; enduring the rigours of a severe winter when sheep of most of the breeds common in Britain would perish. It survives on little food, and shifts admirably for itself in a snowstorm. The small quantity and even inferior quality of food with which a black-faced sheep will tide over a snowstorm is most surprising. So

great indeed is the tenacity of life in black-faced sheep that they have been known to be buried five weeks under a snow-wreath and come out alive. It has a bright, quick eye, with an expression very different from that softness which is seen in many of the breeds preferred for lower grounds and better pastures. The wool is long and coarse, and the weight of the fleece from 3 lb. to 5 lb.; but the mutton is of the finest quality; and on this account, and its hardness, this breed is preferred to any other in many mountainous districts and on rough elevated moors.—The Welsh Sheep is much smaller than the black-faced; both sexes horned; the colour various; the mutton highly esteemed; the fleece seldom weighs 3 lb.—A very little larger breed with short deer-like tail, hornless, or with short and little twisted horns, has long existed in the Shetland Islands, its wool affording the material for the manufacture of Shetland hosiery. The Shetland sheep are very hardy, and in winter feed much on seaweed.—

Fig. 1.—Black-faced Ram.

Smaller than either of these, and indeed is markedly diminutive, is the hornless Breton Sheep — The Forest Sheep of England, so called from being pastured in the royal forests, has now been supplanted by other breeds. The original forest sheep was generally small, with face and legs russet brown or gray, wild, restless, and difficult to fatten, but producing wool of fine quality. — The Dorset Sheep is one of the best of the old English upland breeds. Both sexes have small horns. The wool and mutton are of medium quality; but the ewes are remarkable for their fecundity, and the abundance of their milk—two crops of lambs being bred and reared by them each year. This breed is valued as affording a supply of early lamb for the London market. — The Ryeland Sheep has long existed in Herefordshire and some neighbouring counties of England. It is small, short-limbed, white, hornless; produces

Fig. 2.—Cheviot Ewe.

excellent mutton; and before the introduction of Merino wool its wool was preferred to every other kind for the manufacture of the finest broadcloths. — The Cheviot Sheep has existed from time immemorial on the Cheviot Hills, and is now very widely diffused over a considerable part of England and a large extent of Scotland, being hardy and well adapted for high grounds, although it is inferior in hardness to the black-faced. Cheviots, however, rather excel the black-faced both in size and in the value of the fleece, but require a richer pasture. Ewes are hornless, and the rams almost so. The general figure is longer than that of the black-faced sheep. They are narrow in shape, with slender forequarters and long pricked ears. The colour is white, the face and legs occasionally mottled with gray, but generally quite white. The fleece weighs from 3 to 5 or 6 lb. Great attention has for many years been devoted to the improvement of this breed. — The Leicester Sheep is another of the most valuable breeds. This breed, as it now exists, is a result of

Fig. 3.—Leicester Ram.

the skill and care of R. Bakewell (q.v.), who, soon after the middle of the 18th century, began to make experiments for the improvement of the old Leicester sheep—a large, coarse-boned sheep, not easily fattened, and with coarse long wool, of which, however, the fleece weighed from 8 to 10 lb. The new Leicester sheep has wool moderately long, of better quality, the average weight of the fleece being about 7 or 8 lb., and is easily rendered very fat. It is naturally very broad on the back, with finely-arched ribs. The colour is white. Both sexes are hornless. The Leicester sheep is now common in all but the mountainous parts of Britain; and other breeds have been improved by crossing with it, particularly various breeds of long-woolled sheep, which have long existed in different parts of England, as those of Lincolnshire, Romney Marsh, &c. The Leicester, indeed, was the first to be submitted to improvement by a systematic system of breeding,

and in the general improvement of the sheep stock of the British Isles it has played a larger part than any other breed. One

Fig. 4.—Border Leicester Ram.

crossed breeds is the Border Leicester. — A famous long-woolled breed is the Cotswold, formerly called also the Gloucester, the wool of which was in great esteem in the 14th and 15th centuries, bearing a higher price than any other wool. In 1464 Edward IV. sent a present of Cotswold rams to Henry of Castille; and in 1468 a similar present was sent to John of Aragon. The Cotswold breed, however, as it now exists, has been modified by crossing with the Leicester, and produces shorter wool and better mutton than in former times. — The South Down Sheep has recently been improved with the utmost care. The colour is generally white, and the face and legs are generally brown or fawn. Black and spotted faces and legs were once common, but these are discounted now. Both sexes are hornless. The wool is short, very close, and curled. The South Down derives its origin and name from the chalky downs of the south of England, but is now met with throughout England

Fig. 5.—South Down Ram.

and the south of Scotland. — The Shropshire sheep are large, with thick wool something like the South Down. They are hornless, and black or dun in the face and legs. They come early to maturity, but are suited only for finer climates and good keep. — The Hampshire, also hornless, is a valuable breed of sheep for fattening, matures early, and grows to a large size. It originated in a cross between the Old Wiltshire horned sheep and the Old Berkshire Knot with the South Down. — The Oxford Down, a successful blend of the Hampshire and Cotswold breeds, is a heavy, somewhat soft sheep, without horns, and capable of rapid and great development under good treatment. It is not suited to very cold and exposed situations. The Lincoln, a cross between the improved Leicester and the native sheep of the county, is one of the best long-woolled varieties in England. The

Fig. 6.—Shropshire Ram

Sheep is long and lustrous in the staple, and often exceeds 20 lb. in weight. Other English varieties

Fig. 7.—Lincoln Ram.

of good standing are the Suffolk Down, Devon Long-wools, Romney Marsh Sheep, Wensleydale, Exmoor, Dartmoor, &c. The Roscommon is the principal native breed in Ireland. They are large hornless sheep, improved from the native sheep by a cross of the Leicester.

The first sheep were taken to what is now the United States in 1609, merinos not till 1801; but now 95 per cent. of American sheep are mainly of merino origin, though the breeds have not been kept pure. The principal breeds are native, Spanish, and Saxon Merinos; the New Leicesters or Bakewells; Southdowns, Cotswolds, Cheviots, and Lincolns. The Texas sheep are largely crossed with a Mexican breed, originally from the Basque provinces of Spain. Two races, originating in America, have been allowed to die out—the Smith's Island and the Otter breeds—the latter with a long body and short legs.—Sheep-raising is carried on more or less extensively in Texas, New Mexico, in the Rocky Mountain states, in the uplands of the south-west, in Ohio, and in the northern New England states.

The merino is an important breed of sheep, originally Spanish, but now widely diffused throughout Europe and North America, and constituting a great part of the wealth of Australia. The merino has large limbs, and the male has large spiral horns, which do not rise above the head; the skin of the neck is loose and pendulous; the cheeks and forehead bear wool; the fleece, which is very heavy, often in choice animals exceeding 20 lb., sometimes even over 30 lb., is fine, long, soft, and twisted in silky spiral ringlets, abounding in oil, which attracts dust, so that it has generally a dingy appearance. The fleece is sometimes black, and black spots are apt to appear even in the most carefully bred flocks. The merino sheep fattens slowly, and owes its value altogether to the excellence of its wool. It has not been found profitable in Britain, where the production of mutton is a great part of the object of the sheep-farmer. Merinos are the main breed in Australia, sometimes variously modified by crossing with English long-wooled sheep. In New Zealand the

Fig. 8.—Merino Ram.

Lincoln, Romney, Leicester, and Cotswold breeds are largely represented, as they do not suffer so much from foot-rot as merinos, and their flesh of course tastes more like English mutton.

A clever Australian shearer will clip from seventy to a hundred and twenty sheep in eight and a half hours; the champion shearer of Queensland did three hundred and twenty-seven in nine hours. The Wolseley Sheep-shearer, invented in Australia, consists of a cutting wheel geared to the shaft of a small steam-turbine, which is worked by a current of steam conveyed from the boiler in an india-rubber tube. A comb moves in front of the cutter, effectually protecting the animal from injury. The shearing apparatus, made of brass and in shape similar to a small trowel, is held in the hand and

guided over the body of the sheep just as is the ordinary wool shears. The shearing-machine works with great expedition and perfect safety to the sheep. It will be of great advantage where flocks are large and labourers few.

The Iceland Sheep is remarkable for very frequently having three, four, or five horns—a monstrosity found also in northern Russia.—The north of Africa possesses a breed of sheep with legs of great length, pendulous ears, and much-arched face; the wool short and curled, except on the neck and shoulders, which have a kind of mane.—India has also a hornless breed, with pendulous ears, short tail, and very fine much-curled wool.—The Broad-tailed or Fat-tailed Sheep is found in many parts of Asia, in Barbary, Egypt, &c., and is now abundant in South Africa. It is rather of small size, with soft and short wool. Its chief characteristic is the enormous development of the tail, by the accumulation of a mass of fat on each side, so great that the tail has been known to weigh 70 or 80 lb. The tail is highly esteemed as a delicacy, and to protect it from being injured by dragging on the ground the shepherd sometimes attaches a board to it, or even a small carriage with wheels.—The Fat-rumped Sheep of southern Tataria has a similar accumulation of fat on the rump.—The Astrakhan or Bucharian Sheep has the wool twisted in spiral curls, and of very fine quality.—The Circassian Sheep has a remarkably long tail, covered with fine long wool, which trails on the ground.—The Wallachian Sheep, common in Rumania, is distinguished by the size and direction of its horns, which after one spiral turn rise up from the head to a great length. The wool is soft, and is concealed by long hair.

The importance to Britain of foreign supplies of mutton may be gathered from the articles **FOOD and PRESERVED PROVISIONS**. Reference should be made to the article **WOOL**, and for sheep diseases to the articles on **Anthrax**, **Bot**, **Braxy**, **Fluke**, **Foot-rot**, **Murrain**, **Sheep-pox**, **Sturdy**, &c. See works by G. S. Heatley (1884), C. Scott (1886), J. H. Steel (*Diseases*, 1890); Stephens, *Book of the Farm* (new ed. by Macdonald, 1910); Wallace, *Farm Live-stock of Great Britain* (1885; new ed. 1912), and *Rural Economy and Agriculture of New Zealand and Australia* (1891).

Sheep-dog, a name which often includes the Scottish Collie (q.v.), but which is more properly

Bob-tailed Sheep-dog, 'Wall-eyed Bob.'
(From a Photograph by Gambier Bolton, F.Z.S.)

applied to the English drover's dog. The Sheep-dog or Smooth-coated Collie performs the same work for the south-country shepherd as the

rough-coated for the northern one. The sheep-dog is built on more sturdy and powerful lines than the collie, but lacks the speed of the latter. His coat is short, thick, and wiry; and he is not so graceful as the collie, though possibly quite as useful. Another variety of the sheep-dog is the Bob-tailed or Moorland Collie. When the game-laws were more stringent farmers were only allowed to keep a dog with a docked tail, the current belief being that hares cannot be couised with success by dogs with docked tails. This treatment long continued was alleged to have made the short tail hereditary. The bob-tailed collie has a long, shaggy, and curly coat. The colour is generally a gray or grizzle. As a cattle-dog he surpasses the other varieties, and is also often used for sheep.

Sheep-ked (in some parts KAID), or Sheep Spider Fly (*Melophagus ovinus*), a wingless member of the order Diptera. This insect is common on sheep and lambs, sucking blood and causing skin irritation. It is about $\frac{1}{4}$ inch long, brown-gray in colour, covered with short hair. The female does not lay eggs, but gives birth at intervals of a few days to three to five oval, shining pupæ, and then dies. To the Ked have been given the very unfortunate names of sheep-louse and sheep-tick. It is not to be confused with the common true sheep-lice, *Trichodectes spherocephalus*, in the order Mallophaga; nor with the true sheep-ticks, *Ixodes ricinus* and *Hemaphysalis punctata*, which are not insects at all, but Acarina allied to mites; nor with the minute mites, *Psoroptes communis*, which cause sheep-scab. For all these the shepherd must use appropriate dips.

Sheep-ked (*Melophagus ovinus*):
a, natural size, b, magnified;
c, the pupa, magnified.

Sheep-louse, a mallophagous insect, *Trichodectes spherocephalus*; see LICE. The name is commonly misapplied to the Sheep-ked (q.v.).

Sheep-pox (*Variola ovina*), although resembling the smallpox of men, is a distinct disease, not communicable either by contagion or inoculation to men or children, or even to dogs or goats. It prevailed as an epizootic in England in 1277, was well known for more than 200 years previous to that date, but in more modern times it did not invade the country until 1847, when it broke out in a farm near Windsor, and quickly spread throughout Norfolk and the eastern counties, and in the summer of 1862 in Wiltshire, near Devizes. It is not uncommon on the continent of Europe. Various sheep or infected skins appear in both cases to have imported the disease from abroad. It is scheduled under the Diseases of Animals Acts.

Sheep-scab. See SCAB.

Sheep-scoring Numerals of old Welsh (perhaps Strathclyde) origin, much disguised and turned into jingles, are or were lately used by shepherds in counting sheep in many districts all over Great Britain, especially NW. England. They have been found even among the Indians of Ohio and Maine. They have been used also for counting stitches in knitting, and as counting-out rhymes. The following example is from Borrowdale:

Sheepshead (*Diplodus probatocephalus*), an American fish of the family Sparidae, allied to the perches. It occurs along the east coast from

southern Florida to Cape Cod. The name refers to the shape and colour of the head, and to the teeth, which are broad blades in front and grinding molars on the sides of the jaws. The sheepsheads live near the bottom, especially about oyster and mussel beds or about wrecks, feeding on molluscs and barnacles. In the south they often ascend rivers. Except in spring, when they spawn, they live gregariously. In size they vary greatly, from 2 to 12 pounds' weight. They afford good sport to anglers. The Scup or Porgie (*Stenotomus chrysops*) is nearly allied, and not very far removed is the fresh-water Drumfish (*Haplodimotus grunniens*), to which the name sheepshead is also applied.

Sheep-stealing, in England, is a felony, and by statute 6 and 7 Geo. V. chap. 50, sect 3, is punishable with penal servitude to the extent of fourteen years. In Scotland it is an aggravated species of theft, and under certain old statutes was punishable by death. These statutes have been long ignored, and sheep-stealing, like other thefts, has been punished by imprisonment or penal servitude at the discretion of the judge. And by the Criminal Procedure (Scotland) Act, 1887, a capital sentence is no longer competent in the Scottish courts except on conviction of murder or murderous offences.

Sheerness, a strongly fortified seaport and royal dockyard in Kent, on the north-west extremity of the Isle of Sheppey, at the confluence of the Thames and Medway, 11 miles ENE. of Chatham and 52 E. of London by rail. It consists of three divisions, Blue-town, Mile-town, and Marina-town, and of these the first is within the limits of the garrison. The dockyard, dating from 1814, is one of the finest in Europe, and covers 60 acres, comprising wet and dry docks, immense storehouses, and official residences. The harbour is usually crowded with vessels of all descriptions. The chief trade is in supplying the requirements of the employees in the various government establishments and of the shipping. The neighbourhood was once thought to be very unhealthy, but important sanitary works have been carried out, and now few towns enjoy better health. Of recent years the town has made much progress as a health and pleasure resort. The sea-bathing is excellent. Pop. (1851) 8549; (1921) 18,596. Sheerness was captured by the Dutch under De Ruyter in 1667, and here the mutiny of the *Nore* (q.v.) broke out in 1798.

Sheers. The elemental form of a pair of sheers consists in two spars fastened together near the

Diagram of Sheers.

top with a pulley at the point of junction, and held by a rope fastened to any convenient object,

in such a position that the weight lifted hangs nearly between the spars. This forms an easily improvised crane. An apparatus of this kind of great height and strength is used for masting vessels. In the principal dockyards there are tall permanent sheers, mounted either on the side of a masting-dock or on a floating *sheer-hulk*, often an old dismantled ship devoted to this use.

Sheffield, the largest city in Yorkshire and the fifth largest in England, a municipal, parliamentary, and county borough in the West Riding, is situated on the extreme southern border of the county, at the confluence of the rivers Sheaf and Don, and extends considerably into Derbyshire. It is 46 miles SSW. of York, 18 miles SW. of Doncaster, 38 miles S. of Leeds, 41 miles E. of Manchester, and 165 miles NNW. of London. Lying in a hilly district many of its streets have steep gradients. In 1875 an improvement scheme was commenced for making new streets and widening existing ones in the centre of the city. This was carried out at a cost of over half a million. Amongst the principal buildings are the old parish church of St Peter (now the cathedral), originally built in the early years of the 12th century, but of that structure very little remains, the church having undergone several restorations—the Shrewsbury chapel at the south side of the chancel contains fine monuments to the fourth and sixth earls of Shrewsbury; St Paul's Church, erected in 1721; St Marie's Roman Catholic (1850), surmounted by a spire 195 feet high; the Victoria Hall (Wesleyan Mission); Cutleis' Hall; Corn Exchange; Royal Hospital; Royal Infirmary; Jessop Hospital; Post-office; the University; Technical College; King Edward VII. School (formerly the Wesley College), and others. The dominating building is the Town Hall, begun in 1891, and considerably enlarged in 1923. It was opened in 1897, has two principal frontages in Pinstone Street and Surrey Street, at the corner of which is a lofty clock-tower, surmounted by a bronze statue of Vulcan. In addition to the council chamber and offices of the city officials it contains a fine suite of reception-rooms. The city is well provided with public parks: Norfolk Park (the gift of the Duke of Norfolk), Firth Park (the gift of Mark Firth, Mayor, 1875), Graves Park (the gift of Alderman J. G. Graves, Lord Mayor, 1926), Weston Park, Meersbrook, High Hazels, Millhouses, and Endcliffe. In Weston Park is the principal museum, which contains the well-known Bateman Collection of ancient British antiquities, as well as permanent collections of Sheffield plate, pottery and porcelain, and other antiquities. The Mappin Art Gallery adjoins the museum and contains the collection of pictures formed by John Newton Mappin, both the building and pictures being bequeathed by him to the town. Numerous additions were made to this collection by his nephew, Sir F. T. Mappin, Bart., who was M.P. for Hallamshire for many years. In Meersbrook Park is the Ruskin Museum (formerly the St George's Museum at Walkley) founded by Ruskin, in which he deposited an important collection of minerals, illuminated manuscripts, paintings, drawings, and engravings. There is also a museum at High Hazels, in which are specimens of iron-work, local prints and portraits. The reference library in Surrey Street has been greatly enriched by the Jackson Collection of local pedigrees, charters, manuscripts, and books. There is an up-to-date technical library, and lending-library with eight branch libraries. The university was founded in 1905, and the department of applied science occupies extensive buildings with a fine frontage in St George's Square. Sheffield has long been

noted for the manufacture of Cutleis (q.v.), but at the present day its chief products are iron and steel, which have given it the name of 'Steelopolis.' These trades find employment for many thousands of men, and include the manufacture of railway material, armour-plates, guns, machinery, tools of all descriptions. In addition to which are the older trades of silver and electro-plated goods, and the new one of safety-razor blades. The population (1821), 65,275; (1841), 111,091; (1861), 185,172; (1881), 284,508; (1901), 409,070; (1921), 482,798, but since the widening of the boundaries in 1921 is now about 520,000. There is an excellent service of Corporation trams and motor-buses, by which easy access can be had to the beautiful scenery of Derbyshire and Yorkshire by which Sheffield is surrounded.

Amongst the worthies of Sheffield are Benjamin Huntsman, the inventor of cast-steel, Thomas Boulsover, inventor of Sheffield plate, Sir John Brown, Sir Francis Chantrey, James Montgomery, Ebenezer Elliott, Thomas Creswick, R.A., Sir William Standale Bennett, Joseph Huntel, and J. O. Westwood.

The history of the town commences with Earl Waltheof, who was lord of the manor at the time of the Conquest. A Norman family, De Lovetot, became the resident proprietors of Sheffield and the adjacent parishes, and established a market, a hospital, and a corn-mill. The property descended to a female heir, whose hand was given in marriage by King Richard I. to Gerard Furnival, who had fought with the king at Acre. The Furnivals took the side of Henry III. in his contests with the insurgent barons, during which an expedition was formed against the town and castle of Sheffield, when many of the inhabitants were slaughtered, and the castle burned, in 1266. Four years after this disaster the castle was rebuilt by Thomas de Furnival. His son, of the same name, was the great benefactor of the town, granting what is known as the 'Furnival Charter,' which enfranchised his vassals and gave them a court of justice and trial by jury. This charter is carefully preserved in the archives of the town burgesses. His grandson Thomas took part in the battle of Crécy, and died without issue, the property thus passing to another grandson, William, Lord Furnival, whose only daughter married Sir Thomas Nevil. This pair again left an only daughter, who married John Talbot, first earl of Shrewsbury, made familiar in Shakespeare's *Henry VI.* During the Wars of the Roses the Talbots sided with the Lancastrians, and the second earl fell at the battle of Northampton fighting for the king. His son and successor died young, leaving a son who was only five years old when he succeeded to the title and estates, which he held for 70 years. This earl made the castle a more permanent place of residence than his predecessor had done. It was a fortified building with spacious grounds, orchards, &c., and stood at the northern entrance to the town between the rivers Sheaf and Don. Not a vestige of it now remains. In the early part of the reign of Henry VIII. the earl built a more homely residence about two miles' distance from the castle, surrounded by a large park, which contained some magnificent oak trees and herds of deer. It was here that the earl entertained Wolsey for eighteen days when on his last journey (1530), and here the ill-fated Mary, Queen of Scots, spent some years of her captivity. Very little of this building remains, but the ruins still bear the name of 'Sheffield Manour.' The earls of Shrewsbury were amongst the very chief of the nobility of England, and the sumptuousness of living which they maintained, both at the castle and manour, was second only to that of royalty itself. Queen Elizabeth imposed

on George Talbot, sixth earl of Shrewsbury, the odious responsibility of holding Mary, Queen of Scots, a prisoner in his castle at Sheffield, and she was under his charge for the long period of fourteen years, most of which time was spent in Sheffield (1572-86). Gilbert, seventh earl of Shrewsbury, left three daughters, of whom the youngest only—whose husband was Thomas, Earl of Arundel—had a child, and to this son of the Earl of Arundel the property eventually passed through the entail having been cut. The title, however, passed to Earl Gilbert's brother Edward, and later to a younger branch of the family of Talbot, who still hold it. Through the Earl of Arundel the Sheffield property became henceforth vested in a line of descendants which has made the dukes of Norfolk owners and lords of Hallamshire. Lord Arundel lived much abroad, and the prosperity of Sheffield deteriorated greatly owing to the withdrawal from the local markets of all such custom as two grand mansions had hitherto afforded. Whilst the noble family maintained their loyal sentiments towards the king in the national contest, the townspeople took the side of the parliament. In August 1644 the castle was besieged and taken by the parliamentary army, and soon afterwards a resolution was passed by the government that it should be 'sleighted and demolished.'

Sheffield henceforth became dependent upon its cutlery trade, which as the special business of the town had existed from very early times. The 'Sheffield whittle,' spoken of by Chaucer in the 14th century, was the common knife used for all purposes by those whose social rank did not entitle them to carry a sword. The Cutlers' Company of Hallamshire, which has now a national reputation, was founded in 1624, and the annual feast may date from about that time, having originated in the permission granted by Earl Gilbert to the 'apron men,' or working smiths, to pull down as many deer as they could kill in the park and carry away with their hands. Up to the middle of the 18th century Sheffield was a mean place, and the cutler was a poor man; an income of £100 a year was accounted as riches. But in a century from that time, with railway approaches, the use of the steam-engine, machinery of every sort, and a variety of processes for the manufacture of steel, the growth and progress of the town was rapid, and Sheffield became the 'capital of steel.' It was the first place at which armour-plates to protect British warships were rolled.

The Nonconformist bodies have increased with the population. The old dissent commenced with the ejection of the Presbyterian clergy in 1662, of whose churches the Upper Chapel (Unitarian) in Norfolk Street is now the lineal representative. Sheffield was first enfranchised by the Reform Bill of 1832; by the bill of 1885 it was divided into five, by that of 1918 into seven, divisions, each being represented by one member.

In March 1864 a terrible calamity overtook the town through the bursting of the embankment of the Dale Dyke reservoir at Bradfield. This was a newly constructed dam covering 78 acres and holding 691 millions of gallons of water; the embankment was 95 feet high in the deepest part, and about 420 yards long. The disaster occurred in the night, and the flood swept down the valley with a force which nothing could withstand, doing immense damage and causing great loss of life: 250 persons perished; works, houses, and hamlets were swept away, and apart from the ruin of the dam, damage was done to private property to the extent of £300,000.

Sheffield was incorporated in 1843, became a city in 1893, and since 1896 has a Lord Mayor. In 1891 the see of a bishop-suffragan under York was constituted, and in 1913 Sheffield became a separate see.

See Joseph Hunter's *History of Hallamshire* (1869 ed.); Gatty's *Sheffield, Past and Present* (1873); R. E. Leader's *Sheffield in the Eighteenth Century* (1901); J. D. Leader's *Records of the Burgery of Sheffield* (1897); and *Mary Queen of Scots in Captivity* (1880); *Transactions of the Hunter Archaeological Society*.

Sheffield, JOHN, DUKE OF BUCKINGHAM, was born 7th April 1648, and succeeded to the title of his father, the second Earl of Mulgrave, in 1658. He served in the navy against the Dutch in 1666, and commanded a ship in 1672, but subsequently joined the army. He was lord chamberlain to James II., and a cabinet-councillor under William III., who in 1694 made him Marquis of Normanby. Anne raised him to the dignities of Duke of Normanby and of (the county of) Buckingham (1703); but for his opposition to Godolphin and Marlborough he lost all his offices. After 1710 under the Tory régime he was lord steward of the household and lord president till the death of Anne, when he lost all power, but intrigued zealously for the restoration of the Stuarts. He wrote two tragedies, a metrical *Essay on Satire*, an *Essay on Poetry* (his principal work), and some smaller poems, all of them much talked of at the time, but of little poetic value. He died 24th February 1721.

Sheffield, JOHN BAKER HOLROYD, EARL OF (1735-1821), is chiefly known as the friend of Gibbon (q.v.) and editor of his miscellaneous works. He wrote numerous pamphlets on the slave-trade, the corn laws, the navigation laws, and on commercial and agricultural questions.

Sheikh (Arab., 'elder,' 'aged person'), a title applied to the chieftain of an Arab tribe, to the principal preacher in a Mohammedan mosque, to the head of a religious order, and to a learned man or a reputed saint of Islam. The Sheikh ul-Islam in Turkey is the head of the Mohammedan church; he is possessed of very great influence and power (see **ULEMA**). From 1453 he was nominated by the Sultan; from 1922 by the National Assembly. Persia has likewise a Sheikh ul-Islam, appointed by the government. Sheikh al-Jebel (Old Man of the Mountain) was the name of the chief of the Assassins (q.v.).

Sheil, RICHARD LALOR, Irish patriot and orator, was born at Drumdowney, County Tipperary, 17th August 1791, son of a prosperous Cadiz merchant, who had returned to Ireland about the time that the most odious of the Catholic disabilities began to be relaxed. He passed his earliest years at his father's estate of Bellevue near Waterford, and in due time went to school, first to Kensington, then to Stonyhurst, whence he passed in 1807 to Trinity College, Dublin. Soon after this his father failed, but young Sheil was enabled through the help of friends to graduate B.A. in July 1811, and to enter Lincoln's Inn in November of the same year. He was called to the Irish bar in Hilary term, 1814. The next few years he devoted to literature, producing a series of plays, most of which proved successful at the time. His *Sketches of the Irish Bar*, written in conjunction with the younger Curran, appeared during 1822 in the pages of the *New Monthly Magazine* (2 vols. 1855). In 1823 Sheil joined O'Connell's Catholic Association, which was dissolved in 1825, and throughout gave the great tribune a loyal but an independent support. After the Lords threw out the Catholic Relief Bill (May 1825) he aided his chief in forming the New Catholic Association, and throughout the course of the agitation he devoted enormous labour to the preparation of those ornate and impassioned speeches, which, despite his shrill voice and feeble gestures, had often a magical effect on his audience, and many of which remain to

posterity among the masterpieces of English oratory. After Catholic emancipation was gained in 1829 Sheil devoted much more of his time than before to his profession. He was returned to parliament for Milborne Port, Somerset, a pocket-borough of Lord Anglesea's, and at the dissolution of 1831 for Louth, and later he sat for Tipperary and Dungarvan. After the defeat of Repeal in 1834, which years later he described as 'a splendid phantom,' Sheil mostly supported the Whigs, and in 1838 received a commissionership of Greenwich Hospital. In August 1839 under Melbourne he became vice-president of the Board of Trade, and a privy-councillor—the first Catholic to gain that honour. Under Lord John Russell in 1846 he was appointed Master of the Mint, and in 1850 British minister at Florence. Here he died of gout, 25th May 1851.

See his *Memoirs*, by W. Torrens McCullagh (2 vols. 1855). His *Speeches*, with a memoir by T. MacNevin, were published in 1845; the *Speeches, Legal and Political*, edited by M. W. Savage, in 1855 (2 vols.).

Shekarry (also spelt *shikarry*, *shikaree*, *chickary*; Hind. *shikari*), an Anglo-Indian word for 'hunter,' 'sportsman,' familiar to English readers from the books on sport in India by 'The old Shekarry,' Major H. A. Leveson (1828-75).

Shekel (Heb., from *shaqal*, 'to weigh'), originally a certain standard weight in use among the ancient Hebrews, by which the value of metals, metal vessels, and other things was fixed. Gradually it became a normal piece of money, both in gold and silver, marked in some way or other as a coin, although not stamped. The gifts to the sanctuary, the fines, the taxes, the prices of merchandise are all reckoned in the Old Testament by the shekel, not counted but weighed. Three different kinds of gold, silver, and copper shekels are mentioned: the common shekel, the shekel of the sanctuary (possibly because the standard weight was kept in the Temple), and the shekel of royal weight (2 Sam. xiv. 26). Besides these there was a half-shekel (called *Begal*) and a quarter-shekel (1 Sam. ix. 8). The sacred shekel was equal to 20 gerahs ('beans'), and 3000 sacred shekels made a talent. Originally the Israelites used the Babylonian system, in which the talent (*kikkar*) consisted of 60 minas and each mina of 60 shekels; thus the talent would equal 3600 shekels. But when the Egyptian decimal scale superseded the Babylonian sexagesimal one, the talent contained 3000 shekels. The gold shekel is reckoned approximately to contain 161 Troy grains, the silver shekel 275. During the Babylonian exile the Persian money (*darics*) was used by the captives; nor do the Jews seem to have afterwards used any but the coins of their foreign rulers. It was first under the Maccabees that national money began to be struck. Simon, the 'prince and high-priest,' received, according to 1 Macc. xv. 6, the permission from Antiochus VII. to strike coins in 138 B.C. The emblems are sacred branches, sheaves, flowers, vases, &c., and the legend (in archaic script) contains the date, the name of the Jewish ruler, and the inscriptions 'Shekel of Israel,' 'Jerusalem the Holy,' 'Redemption of Israel.' The latest coins with Hebrew inscriptions date from Barcochba's fight against Hadrian for freedom. The value of the silver shekel is reckoned to be something over two shillings and ninepence. The intricate questions of the weight of the shekel at different periods are discussed in the *Jew. Ency.* (s.v. 'Shekel' and 'Numismatics'). See bibliography there given (and also in *Ency. Brit.* s.v. 'Shekel'); *Jewish Coins*, by Th. Reinach (Eng. trans. by Mrs G. F. Hill, Lond., 1903); *British Museum Catalogue*, by G. F. Hill, and *Handy*

Guide to Jewish Coins, by E. Rogers (privately printed for Spink & Son, 17 Piccadilly, Lond., 1914).

Sheki'nah. See ARK OF THE COVENANT.

Shelburne, WILLIAM PETTY, EARL OF, son of the first earl, and maternal grandson of the famous Sir William Petty (q.v.), was born in Dublin, 20th May 1737, and, after studying at Oxford and serving in Germany, entered the House of Commons for the pocket-borough of Wycombe in 1761, but only sat for a few weeks, the death of his father calling him to the House of Lords. When George Grenville succeeded Bute in 1763 Lord Shelburne was placed at the head of the Board of Trade, and when Chatham formed his second administration in 1766 he became one of the Secretaries of State. Upon the fall of Lord North's ministry in 1782 George III. sent for Shelburne, and proposed to him to form a government. He declined, not being the head of a party, and was sent by the king to the Marquis of Rockingham with an offer of the Treasury, himself to be one of the Secretaries of State. It soon appeared that Shelburne was not so much the colleague as the rival of Lord Rockingham, the chosen minister of the court, and the head of a separate party in the cabinet. Upon Rockingham's death in the following July the king sent at once for Shelburne, and offered him the Treasury, which he accepted without consulting his colleagues. Fox thereupon resigned, and Shelburne introduced William Pitt, then only twenty-three, into office as his Chancellor of the Exchequer. Shelburne's ministry, on the occasion of the king's announcement of his determination to concede the independence of the American colonies, found itself outvoted by the coalition between Fox and Lord North (February 1783). He resigned, and the coalition ministry took his place, but soon broke up. The nation expected that the king on this event would have sent for Shelburne, but William Pitt received the splendid prize, and Shelburne was consoled by being made in 1784 Marquis of Lansdowne. The rest of his days he spent in retirement, amusing himself by collecting in Lansdowne House a splendid gallery of pictures and a fine library, and with the friendship of Priestley, Jeremy Bentham, Sir S. Romilly, Mirabeau, Dumont, and others. He died at Bowood Park, Wiltshire, 7th May 1805. See *Life of Shelburne*, by his great-grandson Lord Edmund Fitzmaurice (3 vols. 1875-76; revised 1912), in which he is shown to have been an advocate of reform, free trade, and Catholic emancipation.

Sheldrake (*Tadorna*), a genus of birds of the Duck family Anatidæ, having the hind-toe free. The Common Sheldrake (*T. cornuta* or *vulpanser*) is one of the most remarkable of all the duck tribe for its size and the beauty of its plumage. It is fully 2 feet long. The head and neck are dark glossy green; below this is a collar of white, and lower still a collar of rich chestnut extending over part of the back; the rest of the back is white; the middle of the under-parts is black; the wing speculum green, the primaries and part of the secondaries black; the bill and frontal knob bright carmine; the legs, feet, and webs flesh pink. The female is rather smaller and duller, and has no frontal knob. The sheldrake is confined to salt water, and is found upon flat shores, links, and sand-bars on various parts of the coasts of the British Isles. It is abundant in Sweden, Denmark, the Baltic, and Norway; it is a winter visitor to the Mediterranean, but resident in the Black Sea and the Caspian; it is found in Asia in salt lakes, and as far as Japan. It breeds in burrows made by rabbits and foxes in sand-dunes (hence the name Burrow Duck by which it is sometimes called), or it may make its own burrows. In

some sandy islands off the coast of Jutland burrows are made by the inhabitants, who protect the birds

Common Sheldrake (*Tadorna vulpanser*).

for the sake of their eggs and down. The food consists of small molluscs, sand-hoppers, and seaweed. The flesh is coarse and unpalatable. The note of the male is a shrill whistle; the female utters a harsh bark. The Ruddy Sheldrake (*T. rutula* or *casarca*) is rare as a British bird, and not common anywhere north of the Alps and Carpathians. It is not uncommon in Spain and various parts of North Africa. It is more abundant in the Black Sea area, southern Russia, and the elevated parts of Asia as far as China and Japan. In India, where it is known as the Brahminy Duck, it is very common during the cold season. Four other species are found respectively in South Africa, the Malay Archipelago, Australia, and New Zealand. The name is doubtless derived from *shield*, from the markings on the plumage. Other names are Skeel-duck, Skeeling-goose, Sly-goose, St George's Duck, and Bargander.

Shell, a general name for the hard enclosure or exoskeleton of many different kinds of animals, and including a great variety of structures, differing in composition, texture, and development. Many Protozoa have shells of lime (as in most Foraminifera), or of flint (in most Radiolarians), which may be distinguished as inorganic shells from organic shells such as those of acanthin (a protein skeletal substance found in many Radiolarians). As all these shells are the results of chemical processes (metabolism) in the living matter, they may be distinguished from shells of extraneous materials—e.g. in the arenaceous Foraminifera. Yet in the cementing of the extrinsic particles a secreted material may be used. The same contrasts recur at a higher level. Thus among Polychaet worms there are shell-tubes of lime and shell-tubes of organic material; there are shell-tubes secreted by the worm and others in the main extrinsic, consisting of sand-grains and the like cemented by a secretion. For the hard parts of corals of the Madreporarian type, the word shell is quite appropriate. The various parts are secreted by the outer layer of ectoderm, and though they may seem to intrude into the interior, the flesh of the polyp recedes before the passive growth of the walls and partitions which the process of secretion effects. Such ectodermic shells are very different from those of sea-urchins and some other Echinoderms, which are mesodermic in origin, and are added to by the secretory activity of enveloping mesoderm cells. They may seem to be external, but they are surrounded during life by transparent ciliated ectoderm.

The cuticular type of shell finds abundant illustration among Arthropods—e.g. crab and lobster, king-crab and beetle. It consists of an external

armature, not in itself living or cellular, which is made and remade by the underlying living skin. During the period of growth it is periodically moulted and replaced. In all cases there is an organic basis of chitin produced in the periphery of the epidermic cells; to this in crustaceans and king-crabs lime is added. The shell of a typical crustacean, such as the crayfish, consists of laminated chitin, impregnated with lime-salts (furnished by the blood), and containing a pigment called zoöerythrin. The hardness of the shell or cuticle of many insects is mainly due to the thickness of the chitin; there are traces of copper in some beetles, and rare instances of calcareous hardening have been noted. It is quite possible that shells primarily expressed a method of dealing with waste-products, and it may be noted in this connection that chitin is a nitrogenous carbon-compound.

Another type of shell is characteristic of molluscs. It is also cuticular, and is typically a product of the fold of skin known as the mantle. There is an organic foundation of conchin or conchiolin, allied to chitin, and on this there is deposition of carbonate of lime. It is non-cellular and non-living like the shell of Arthropods, but it does not require to be moulted, since a free edge is retained, at which enlargement can be made in correspondence with the animal's growth. Apart from the organic matrix, the molluscan shell typically consists of pure carbonate of lime, but a little phosphate may be present, or a trace of carbonate of magnesia and the like. The lime may be laid down in granular or in crystalline form; if the latter, it may be either calcite or aragonite, sometimes both in one shell. The texture may be nacreous or porcellaneous; and almost all molluscan shells show layers of laminae, transversely or longitudinally disposed. In all molluscs there is an embryonic shell-sac which makes an embryonic shell; the adult shell, if there is one, is mainly a product of the mantle. In the Brachiopods or Lamp-shells, which are not in any way related to molluscs, the dorsal and ventral shell-valves are composed of small prisms or spicules of lime with a variable quantity of organic matrix, and in many cases there are numerous tubules or pores through the shell containing extensions of the mantle and of the skin of the body.

The word shell also finds application among back-boned animals. Thus tortoise-shell consists of epidermic horny plates, and the subjacent bony encasement of Tortoises (q.v.) and Turtles is a very intricate combination of exoskeleton and endoskeleton. Even the Armadillo (q.v.) among mammals may be said to have a shell—a unique armature of ossified integumentary plates.

See Rolleston's *Forms of Animal Life*, 2d ed. 1888, p. 127, giving a discussion of shells and references to literature. See also BIVALVES, CONCHOLOGY, EGG, FORAMINIFERA, IRIDESCENCE, MOLLUSCA, PEARL, &c. For vegetable shells, see DIATOMS, NUT. For shells in religion and magic, see MAGIO, IMAGES, CHANK SHELL. For shells as money, see COWRY.

Shell, a hollow projectile containing a bursting-charge of gunpowder or other explosive, and exploded, as desired, either in the air or on striking some object, by either a time or percussion fuse (see FUSE). In the past shells were spherical in form; but after the introduction of rifling elongated shell, as shown in the figures, were introduced.

Fig. 1 is a 'common' shell. Formerly these shell were made of cast-iron and filled with gunpowder; but they are now more usually made of the best forged mild steel and filled with a high explosive. In either case they are exploded by a fuse—generally percussion—screwed into the fuse-hole at their noses. A variant of this shell is the 'segment' shell, with lines of weakness cut in the

walls to make it burst into many pieces. It is not now much used. During the war of 1914-18 common shells, suitably modified and filled with smoke-producing composition and poisonous gases (see BOMB), were used very largely, and, to a lesser extent, filled with incendiary compositions. Special flaming shell were introduced for the attack of air-ships.

Fig. 1.

Fig. 2 is an armour-piercing ('A.P.') shell. Its cavity is much smaller proportionally than that of a common shell, as it needs a very strong head. A high-class A.P. shell will perforate, without breaking up, a plate of the best hardened steel of a thickness equal to its (the shell's) diameter, if it have a striking velocity of about 1800 to 2000 feet per second, and if it strike the plate at right angles. The perforative power, without breaking up, falls off very rapidly if the striking velocity be diminished, or if the impact be oblique. It will be noticed that the shell has a cap over its point. This cap (of soft steel) undoubtedly does assist a shell to perforate armour, but the exact way in which the cap does its work has been the subject of much discussion, and no explanation has been universally accepted. A modern armour-piercing shell is made of one of the best 'alloy' steels of the chrome or chrome nickel class. The 'Palliser' A.P. shell, made of cast-iron specially hardened, was efficient against the old wrought-iron armour, but would be quite useless against modern hardened steel. A.P. shell are filled with gunpowder or high explosive—recently more usually the latter—and have base percussion-fuses. There is also a capped semi-A.P. shell, with a larger bursting-charge, capable of piercing about half its diameter of armour.

Fig. 2.

Fig. 3 shows a Shrapnel shell. It is filled with bullets, with melted tin run in round them, and has a small bursting-charge in the cavity at its base, which is fired by the flash, passing down the tube in the centre of the bullets, from the fuse (shown dotted), screwed into the nose of the shell. Fig. 3 shows powder-pellets in the tube; these are sometimes not used. This shell is essentially a man-killing projectile, and is burst in the air by the time-action of a time and percussion fuse (see FUSE) a short distance in front of the troops attacked. When it explodes, the bursting-charge drives the bullets out of the shell in a coned shower, the angle of the cone being from 20 to 30 degrees. The bullets have the velocity of the shell at the time of bursting, with a small additional velocity due to the bursting-charge. For ranging purposes, or for the attack of troops only protected by light cover, it is burst on percussion. This shell was invented by Colonel Henry Shrapnel, R.A., in 1784, originally of course as a spherical shell; but its first trial did not take place until 1803. Its complete success depends on a good time-fuse, and as a result it was not adopted abroad until quite late in the 19th century. It is now universally adopted for field-artillery.

Fig. 3.

Efforts have been made in the past to produce a shell which shall have the properties of both the common and the Shrapnel shell. In one form some of the bullets in a Shrapnel shell are sacrificed to make room for an inner shell filled with high

explosive. Such shell have not as yet been adopted, nor, from recent war experiences, is it likely that they will be.

Star shell are shell which when burst by time-fuse send out a shower of burning stars. The latest practice is to use only one large star, which is supported by a parachute as it falls and gives light for a much longer time. They are used for illuminating the ground in front of a position. All shell fired from modern breech-loading guns have diving-bands near their bases, by which they are rotated by the rifling. Muzzle-loading guns had studs in their walls, or rotating gas-checks on their bases, for the same purpose. See also SHOT; and for 'tracers' for shell, see CANNON.

Shellac. See LAC.

Shelley, MARY WOLLSTONECRAFT, daughter of William Godwin and Mary Wollstonecraft, and wife of the poet Shelley, was born August 30, 1797. Her life from 1814 to 1822 was bound up with that of Shelley. Her first and most impressive novel, *Frankenstein*, had its origin in a proposal of Byron's, made in 1816 at his villa on the Lake of Geneva, that Mary and Shelley, Polidori (Byron's young physician), and Byron himself should write each a ghost story. *Frankenstein* (q.v.) was published in 1818. The influence of Godwin's romances is apparent throughout. Her second tale, *Valperga, or the Life and Adventures of Castuccio, Prince of Lucca* (1823), is a historical romance of mediæval Italy. In 1823 she returned to England with her son. Her husband's father, in granting her an allowance, insisted on the suppression of the volume of Shelley's *Posthumous Poems*, edited by her; and she was obliged to submit. *The Last Man* (1826), a romance of the ruin of human society by pestilence, fails to attain sublimity, but we can trace in it with interest idealised portraits of some of the illustrious persons most intimately known to her. In *Lodore* (1835) we read under a disguise the story of Shelley's alienation from his first wife. Her last novel, *Falkner*, appeared in 1837. She published several short tales in the annuals, some of which have been collected and edited by Dr Garnett. Of her occasional pieces of verse the most remarkable is *The Choice*. She wrote also many of the lives of Italian and Spanish literary men in Lardner's *Cabinet Cyclopædia*. Her *Journal of a Six Weeks' Tour* (partly by Shelley) tells of the excursion to Switzerland in 1814; *Rambles in Germany and Italy* describes a series of tours in her later years. She will be remembered by *Frankenstein* and her admirable notes—in large part biographical—to her husband's poems. Those who knew her intimately valued Mary Shelley for her nobility of character, even more than for her fine intellect. She died February 21, 1851, and was buried in Bournemouth. In 1922 Koszul edited two short plays, *Proserpine* and *Midas*. See SHELLEY (PERCY BYSSHE), GODWIN (WILLIAM), GODWIN (MARY W.).

Mrs Julian Marshall wrote a valuable Life of Mary Wollstonecraft Shelley (2 vols. 1889); and there is a short Life of her by Mrs W. M. Rossetti.

Shelley, PERCY BYSSHE, one of the greatest of English poets, was born on 4th August 1792, at Field Place, near Horsham, Sussex, the eldest child of Timothy Shelley and his wife Elizabeth, daughter of Charles Pilfold of Effingham, Surrey. The family was old and honourable. Bysshe Shelley, the poet's grandfather, married two heiresses, acquired a great property, and in 1806 received a baronetcy; in 1815 he died. Percy was a boy of much sensibility, quick imagination, and generous heart; physically of a refined type of beauty, blue-eyed, golden-haired. At ten years old he became a pupil of Dr Greenlaw's at Sion

House School, Isleworth, where he made some progress in classics, listened with delight to lectures on natural science, and endured much rough handling from his schoolfellows. In 1804 he passed to Eton, where Dr Goodall was then head-master. He continued his study of the classics, read eagerly Lucretius and Pliny, became a disciple of the 18th-century sceptical and revolutionary writers, pored over Godwin's *Political Justice*, filled his imagination with the wonders of modern science, resisted the system of school-fagging, and held aloof from the throng of the schoolboys, who in turn made him the object of systematic persecution. While still at Eton he wrote a crude romance, in the manner of M. G. Lewis, which was published with the title *Zastrozzi* in April 1810. Before the close of the year a second romance, *St Irvyne, or the Rosicrucian*, appeared; it is as absurd as its predecessor in its sentimental extravagance, its pseudo-passion, and mock sublimity. He assisted his cousin Thomas Medwin in a poem on the subject of *The Wandering Jew* (1810), and issued with a fellow-rhymers a long-lost volume of verse, *Original Poetry by Victor and Cazire* (1810; ed. by R. Garnett, 1898). His collaborator was his sister Elizabeth, and not his cousin Harriet Grove, whom Shelley loved with a boy's passion. Her parents, alarmed by Shelley's religious scepticism, put a stop to the correspondence between the cousins. In April 1810 Shelley matriculated at University College, Oxford, and in Michaelmas term entered on residence. His chief friend was a student from Durham, Thomas Jefferson Hogg, who has left a most vivid account of Shelley's Oxford life. Hogg was shrewd, sarcastic, unimpassioned, and withal a genuine lover of literature. He aided Shelley in putting forth a slender volume of poems, originally written by Shelley with a serious intention, now retouched with a view to burlesque—*Posthumous Fragments of Margaret Nicholson*—the pretended authoress being a mad washerwoman who had attempted the life of the king. In February 1811 a small pamphlet by Shelley, entitled *The Necessity of Atheism*, was printed. When it was offered for sale in Oxford, the college authorities conceived it their duty to interfere; Shelley and Hogg were interrogated respecting its authorship, and having refused to reply, were expelled from University College (March 25, 1811) for contumacy and for declining to disavow the pamphlet. For a time the friends lived together in London lodgings; then Hogg departed to the country and Shelley remained alone. In his solitude he found some pleasure in the society of a schoolfellow of his sisters at Clapham, Harriet Westbrook, a fresh and pretty girl of sixteen, daughter of a retired coffee-house keeper. She moved under the tutelage of an unmarried sister nearly twice her own age. When summer came Shelley was with cousins in Wales; letters reached him from Harriet in London complaining of domestic persecution, and speaking of suicide as a possible means of escape; a letter followed in which she threw herself on Shelley's protection, and proposed to fly with him from her home. Shelley hastened to see her, but at the same time assured a cousin that he did not love Harriet, though he was prepared to devote himself to her through a sentiment of chivalry. On meeting him she avowed her passion, and he left her with a promise that if she summoned him he would come at her call and make her his. The summons came speedily; Shelley and Harriet, aged nineteen and sixteen, took coach for Edinburgh, and were there formally united as man and wife on 28th August 1811. He assured his bride that, in accordance with principles which he firmly held, the union of man and wife might be dissolved as soon as ever it ceased to contribute to their mutual happiness.

Coming from Edinburgh to York, where Hogg resided, the young married pair were joined by Eliza Westbrook, the elder sister. Ill conduct of Hogg towards Harriet caused a temporary alienation between the friends. The Shelleys with Eliza moved to Keswick, where Southey's presence was an attraction. Southey was kind and helpful, but his lack of revolutionary ardour and his indifference to metaphysical speculation displeased Shelley. The young enthusiast found a monitor more to his liking in Godwin, with whom he now corresponded as a disciple with a master. To apply at once his ideas of reforming the world he resolved to visit Ireland, and there advocate Catholic emancipation and Repeal of the Union. On reaching Dublin he printed and scattered abroad an *Address to the Irish People*, written at Keswick. This was soon followed by a second pamphlet, *Proposals for an Association of Philanthropists*. He spoke at a large public meeting from the same platform with O'Connell, and made the acquaintance of Curran. Discouraged by the small results of his efforts, and yielding to Godwin's advice, he left Ireland (April 4, 1812), and after some wanderings in Wales found rest in a cottage at Lynmouth, then a lonely fishing-village. Here he received as a visitor Miss Hitchener, a Sussex schoolmistress, whom both before and for a time after his marriage he had idealised into all that is most heroic and exalted in womanhood, and with whom he was ere long more than disenchanted. He wrote a vigorous pamphlet on behalf of liberty of printing—the *Letter to Lord Ellenborough*—amused himself with circulating, by means of bottles and boxes set afloat in the Channel and by fire-balloon, copies of his satirical poem *The Devil's Walk* and his revolutionary broadsheet *Declaration of Rights*, and was at work on his *Queen Mab*. His servant, having been found posting up at Barnstaple the offensive broadsheet, was imprisoned, and Shelley crossed to Wales. He took up his abode at Tremadoc, where he was much interested in the scheme of a great embankment against the sea. In October he made Godwin's personal acquaintance in London. During the winter he was active in the relief of the suffering poor of Tremadoc, studied history and philosophy, and added to his manuscript poems. On the night of 26th February 1813 an aggrieved shepherd attempted to enter the lonely house of Tanyrallt. Some have thought that Shelley with over-heated fancy conjured up such an outrage. He hastily quitted Tremadoc, and, after an excursion to Dublin, Cork, and Killarney, once again settled in London. In June 1813 his wife gave birth to a daughter who was named Ianthe (married to Mr Esdaile, died 1876). On Harriet's recovery some stay was made at Bracknell in Berkshire. *Queen Mab* was printed for private distribution, its religious and political views being considered too hostile to received opinions to admit of public circulation. The poem sets forth Shelley's youthful conceptions of the past history of humanity, its present evils, and future progress. It is often crude, often rhetorical, yet there is more than a promise of poetical power in certain passages. In the autumn (1813)—perhaps to obtain time to settle with creditors—Shelley and his household went northward to the English Lakes, and thence to Edinburgh, but before the new year opened he was settled at Windsor. About this time he wrote a prose dialogue (published 1814), *A Refutation of Deism*, designed to prove that there is no *via media* between Christianity and Atheism.

In March 1814 Shelley went through the ceremony of marriage with Harriet according to the rites of the English Church, probably to set at rest any doubts of the validity of the Scotch marriage. He was endeavouring to raise large sums of money

on Godwin's behalf, and the marriage may have been considered advisable to render certain the legitimacy of a future son and heir. Four months later he had separated from his wife for ever. Their early married happiness had become hopelessly clouded; an attempt at reconciliation made by Shelley in May was rejected. Harriet withdrew to Bath. It was stated by Miss Clairmont, the daughter of Godwin's second wife, that Shelley declared in July 1814 that Harriet had yielded herself to a certain Major Ryan, and Godwin in 1817 stated in writing that he had evidence independent of Shelley of her unfaithfulness before Shelley left her. No such evidence is in our possession to-day, and statements to the contrary were made by Harriet herself and by several persons who knew her well. The division between husband and wife, whatever its causes, was deep. Shelley had become suddenly and passionately enamoured of Godwin's daughter, Mary, a girl of fine intellect and vigorous character. Having informed Harriet of his resolve to leave her finally, and having made arrangements for her material comfort, he took flight to the Continent with Mary Godwin on 28th July 1814. Miss Clairmont accompanied the fugitives. Shelley was inexperienced enough to suppose that Harriet could still regard him as a considerate friend, though no longer her husband.

After a journey across France and a short stay in Switzerland, Shelley and his companions returned by the Rhine to England. The last months of 1814 were full of vexation caused by debts and duns. But in January 1815 Shelley's grandfather died, and by an arrangement with his father he obtained an income of a thousand a year. His health unhappily showed the effects of the previous year's strain and excitement. He sought rest and refreshment in Devon, and in August found a home at Bishopsgate, on the edge of Windsor Forest. In the autumn of 1815 *Alastor*, his first really admirable poem, was written. It tells of the ruin of an idealist who, pining for absolute love and beauty, shuns human society; its visionary landscapes have the largeness and ideality characteristic of Shelley. In January 1816 Mary gave birth to a son, who was named after her father; but Godwin still held aloof. It was decided to try life upon the Continent, and in May Shelley and Mary travelled through France to Geneva. Miss Clairmont, whose intrigue with Byron was unknown to Shelley and Mary, accompanied them. On the shores of the Lake of Geneva a meeting took place between Byron and Shelley. They rowed and sailed together on the lake, and Shelley in company with Mary made an excursion to Chamouni. In the poem *Mont Blanc* and the *Hymn to Intellectual Beauty* we find a poetic record of the impressions of these memorable days.

In September they were once more in England. The suicide, following a state of deep depression, of Fanny, the half-sister of Mary (see GODWIN, WILLIAM), gave Shelley a great shock, and this disaster was soon followed by the death of Harriet Shelley. For some time past Shelley had in vain inquired for her. She had formed an irregular connection with one who, it is believed, deserted her. On 10th December her body was discovered in the Serpentine; had she lived she would soon have given birth to a child. It was another severe shock to Shelley, but he always maintained that he himself was 'innocent of ill, either done or intended.' Free now to make Mary his lawful wife, he at once celebrated his marriage (30th December 1816). A long Chancery suit followed, Shelley seeking to obtain possession of his daughter Ianthe and his son Charles (born November 1814—died 1826), the Westbrooks

resisting. At length Lord Eldon gave judgment which compromised the matter; Shelley's opinions being such as led to immoral and illegal conduct, he was disqualified for bringing up his children, but he might appoint caretakers and tutors to be approved by the court. The blow was deeply felt by Shelley. While the Chancery affair was proceeding he was cheered by the friendship of Leigh Hunt and of Horace Smith. His home was at Marlow on the Thames, and here he wrote fragments of his *Prince Athanase*, a portion of *Rosalind and Helen*, and his long narrative poem *Laon and Cythna*, designed to sustain men's hopes in ideals of freedom and progress during days of political reaction. When some few copies of *Laon and Cythna* had been issued the publisher withdrew it from circulation, and induced Shelley to alter certain lines and phrases which might give offence. As thus revised the poem was issued with a new title, *The Revolt of Islam*. During his residence at Marlow Shelley worked earnestly and systematically in the relief of the poor. He printed two pamphlets, *A Proposal for Putting Reform to the Vote*, by 'The Hermit of Marlow,' and *An Address to the People on the Death of the Princess Charlotte*. In the spring of 1818 it was feared that he was threatened with pulmonary disease. He decided to seek a southern climate, and in April, with Mary, little William, an infant daughter Clara (born 2d September 1817), Miss Clairmont and her child Allegra (Byron's daughter), he left England for Italy, never again to see his native land.

In the summer of 1818, at the Baths of Lucca, Shelley completed his *Rosalind and Helen*, and made his translation of Plato's *Banquet*. Grief came with the autumn; little Clara died on 24th September at Venice, where Shelley had been renewing his companionship with Byron. Memorials of this visit to Venice, with an idealised presentation of Byron, will be found in the admirable poem *Julian and Maddalo*. He contemplated a tragedy of *Tasso*, but this was set aside in favour of his great lyrical drama *Prometheus Unbound*, the first act of which was written at Este, September–October 1818. Seeking a warmer climate for the winter, he journeyed to Rome, and thence to Naples. His letters descriptive of Southern Italy are full of radiance and luminous beauty. In the spring (1819) he was again in Rome, and found great delight in its classical sculpture and architectural remains. Among the ruins of the Baths of Caracalla he wrote the second and third acts of *Prometheus*. The fourth act—not originally conceived as part of the poem—was added before the close of the year at Florence. On 7th June 1819 Shelley's beloved son William died at Rome. The afflicted parents sought the neighbourhood of kind friends near Leghorn, and here—at the Villa Valsovano—Shelley wrote the greater part of his dark and pathetic tragedy *The Cenci*. At Leghorn the first edition was printed in quarto. The other works of this memorable year were written at Florence—a prose treatise called *A Philosophical View of Reform* (still unpublished in its entirety); a poetical appeal to his countrymen on the occasion of the 'Peterloo' affair, entitled *The Mask of Anarchy*; a grotesque satire suggested by the supposed failure of Wordsworth's poetic powers under the blight of Toryism—*Peter Bell the Third*; a translation of *The Cyclops* of Euripides; and in addition to these some of his noblest lyrical poems, among them the magnificent *Ode to the West Wind*.

On 12th November 1819 a son was born to comfort his father and mother, Percy Florence (died 5th December 1839). The climate of Florence was found trying, and in January the Shelley household moved to Pisa, where was spent the

greater part of the poet's remaining days. The year 1820 was less productive than 1819. The charming poetical *Letter to Maria Gasborne*, a spirited translation of the Homeric *Hymn to Mercury*, the brilliant fantasy of *The Witch of Atlas*, the satirical drama *Edipus Tyrannus* or *Swellfoot the Tyrant*, which deals not very happily with the affair of Queen Caroline, are the chief writings of 1820. As the year was closing the Shelleys made the acquaintance of a beautiful girl, Emilia Viviani, who was confined in the convent of St Anna. To Shelley's imagination for a brief time she became the incarnation, as it were, of all that is most perfect, all that is most radiant in the universe. At such a moment he wrote his *Epipsychidion*, which is rather a homage to the ideal as seen in womanhood than a poem addressed to an individual woman. It was followed by a remarkable piece of prose—the critical study entitled *A Defence of Poetry*.

A small circle of interesting friends had gathered about Shelley at Pisa. Among these were Edward Williams, a young lieutenant of dragoons, and his wife Jane, to whom many of Shelley's latest lyrics were addressed. In the summer of 1821 the Shelleys and Williams had much pleasant intercourse at the Baths of San Giuliano. The elegy *Adonais*, suggested by the death of Keats, was here written; it is Shelley's most finished piece of art. In the late summer or autumn he swiftly composed his *Hellas*, a lyrical drama suggested by passing events in Greece. Early next year Byron was settled in Pisa, and Shelley had also an interesting new companion in Trelawny, a young man of ardent and romantic temper. Shelley worked somewhat tentatively at his unfinished historical drama *Charles I.* His last great poem, also unfinished, *The Triumph of Life*, was written in his boat near Casa Magni, a lonely house on the eastern side of the Bay of Spezzia, occupied as a summer residence by the Shelleys, together with Edward and Jane Williams. On 19th June Shelley heard of the arrival in Italy of Leigh Hunt and his family. He and Williams, some days later, set sail for Leghorn. The meeting with Hunt was full of joy and hope. On Monday, 8th July, Shelley and Williams left the port of Leghorn with a favourable breeze; the boat was observed at ten miles distance; then it was lost in sudden storm and mist. Dreadful uncertainty for a time came upon the two widowed women at Casa Magni. On 19th July the bodies were found upon the shore near Via Reggio. By special permission they were consumed by fire in the presence of Trelawny, Hunt, and Byron. The ashes of Shelley were placed in a casket, and were afterwards interred in the Protestant burial-ground at Rome.

In person Shelley was tall and slight, and if not of exact formal beauty of face had a countenance full of spiritual beauty, radiant with its luminous blue eyes. His portrait, painted in Rome by Miss Curran, is the only likeness of Shelley in manhood. His poetry is inspired by an ardent passion for truth, an ardent love of humanity; it expresses desires and regrets with peculiar intensity, but also sets forth a somewhat stoical ideal of self-possession, as if to balance the excessive sensitiveness of its author. The earlier poetry is aggressive and doctrinaire, embodying the views and visions of Godwin's philosophy; the later is more purely emotional. Shelley's creed, which passed at an early stage from deism to atheism, rested in his mature years on a spiritual conception of the universe.

An edition of Shelley's *Complete Works* in 10 vols., ed. Ingpen and Peck, began in 1926 with his correspondence (vols. viii., ix., x.). The standard edition of Shelley's works in verse and prose is that of H. B. Forman (8 vols. 1876–80). Forman also edited an

admirable text of the poetical works in two volumes. Rossetti's edition of the poetical works is of great value. The most complete one-volume edition of the poetical works is that by Thomas Hutchinson (1904). The prose works were edited by Shepherd (1888), the letters by Ingpen (1909; enlarged 1915). *A Philosophical View of Religion* was first printed in 1920 (ed. T. W. Rolleston). Dowden's is the fullest and most exact Life of Shelley (2 vols. 1886). Short Lives have been written by Symonds, Rossetti, Salt, and W. Sharp, and by his daughter-in-law, Lady Shelley. Hogg's Life is excellent for the months at Oxford. Trelawny's *Records* gives a vivid picture of Shelley during his last days. Biagi's *Gli Ultimi Giorni de P. B. Shelley* (1922) contains the most authentic account of his death. See also books by Elton (1894) and Ingpen (1917); Francis Thompson's essay (1909); Clutton-Brook's study (1909); Mrs O. W. Campbell's *Shelley and the Unromantics* (1923); T. Spira's *Shelley's Geistesgeschichtliche Bedeutung* (Giessen, 1923). Forman's *Shelley Bibliography* (1882) is full and accurate, and there is an essay by Chevrillon in his *Études Anglaises*. The publications of the Shelley Society include reprints of several rare editions. An admirable *Lexical Concordance* to Shelley's poems was published by F. S. Ellis in 1892.

Shell-fish, a popular term for many aquatic animals not fishes (in the sense in which the word 'fish' is now understood); especially oysters, clams and all molluscs, and crustaceans such as crabs and lobsters.

Shell-lac. See LAC.

Shells. See SHELL.

Shell-sand. Sand consisting in great part of fragments of shells, and often containing a small proportion of organic matter, is a very useful manure, particularly for clay soils, heavy loams, and newly-reclaimed bogs. It is also advantageously applied to any soil deficient in lime. It neutralises the organic acids which abound in peat, and forms with them compounds which serve as food for plants. Great deposits of shell-sand are found on the coasts of Devonshire and Cornwall, and are of much value in the agriculture of that district. Shell-sand is also found on many other parts of the British coast, and nowhere more abundantly than in the Outer Hebrides. The sand of many parts of the coast being mostly siliceous is incapable of the same use. Shell-sand is much used as a manure in some of the maritime districts of France, as Bretagne and Normandy.

Shelta, or SHELTRU, is a secret jargon of great antiquity spoken by Irish tinkers, beggars, and pipers, the descendants of the ancient ceards and bards. The word Sheltrú is a perversion of the Irish *béultra*, 'language.' Shelta is otherwise known as 'Cainnt chara,' 'Minkur-tharal,' 'Gam (or Gamoch) cant,' 'Bog-latin,' and 'Béarl' eagair.' For use of last name see *Gaelic Dictionary of the Highland Society* (1828), i. 113: "'Beurl' eagair" or "'Laidiann nan ceard," the gibberish of tinkers: *figulorum striligo*; *dialectus qua utuntur ollarum sartores circumforanei*;' also i. 548: 'Gibberish: *mendicorum et nebulonum ex compacto sermo, barbaries*.' Béarla eagair (i.e. 'vernacular') thus used must not be confounded with Béarlágair na saor (mason's jargon), a few words of which are given by MacElligott (*Dublin Gaelic Society*, 1808). The earliest specimens of this idiom, collected (1877–80) by C. G. Leland from an English vagrant in North Wales and an Irish tinker in Philadelphia, are published in *The Gypsies*, pp. 354–372. The investigation of Shelta was continued by D. MacRitchie in the *Journal of the Gypsy Lore Society* (i. 350–357), where fresh examples from the Scottish Highlands and south of Ireland subsequently appeared. In the same *Journal* (ii. 204–220) Mr John Sampson showed Shelta to be a systematic perversion of the preaspirated Gaelic

spoken anterior to the 11th century, and Dr Kuno Meyer (ii. 257-266) in an erudite paper on 'The Irish Origin and Antiquity of Shelta' adduced numerous references to this jargon in early Irish MSS. Shelta has been identified by Dr Meyer with the ancient secret language called Ogam (q.v.), a word probably surviving in the name Gam or Gamoch cant. References to Ogam as a spoken tongue occur in the *Annals of Clonmacnoise* (1328) and in O'Molloy, *Grammatica* (1677), p. 133. Several common Shelta words are found in the *Dial Laithne* or Book of Latin (cf. 'Laidionn nan ceard'; for Latin = cant, see Pott's *Zigeuner*, i. 8), an Ogam glossary copied by MacFibris from an old or middle Irish MS. Professor Thurneysen (*Revue Celtique*, vii. 369-375) has shown that many of these Ogam words are formed by substituting for the initial its runic name: thus *manaith* (*D. L.* 137 = Shelta *máinn*) is formed from *Ir. maith* by changing *M* into *muan*, the name of the letter; Shelta *nadherum*, 'mother,' being similarly an anagram of *muanathair* (*Ir. mathair*). Shelta words are also fabricated from Irish by reversing or transposing the letters of the original word (e.g. *grê*, 'rise,' *Ir. érg*; *tober*, 'road,' *Ir. bothar*), by changing the initial (e.g. *júnnik*, 'Sunday,' *Ir. domnach*), and by the prefix, suffix, or interpolation of arbitrary letters to the Irish word or its anagram (e.g. *gladher*, 'skin,' *Ir. leathar*; *thalosk*, 'day,' *Ir. latha*; *srigo*, 'king,' *Ir. rí*; *laskon*, 'salt,' *Ir. salann*). Analogous modes of word-disguise are described in the *Amra Choluimchille*, an Irish MS. of the 12th century, and in the *Uraicept na n-Eges* (Primer of the Poets), each of these processes having a recognised name. A few old Irish words are used in Shelta without disguise, as *kúnya*, 'priest,' *Ir. cúrneach*, 'druidical priest'; *gyukera*, 'beggar,' *Ir. geocaire*. Shelta borrows its grammar and unimportant words from Irish or English. The following translation of the Lord's Prayer ('Staffara a' Dhalyon') by an old Irish tinker illustrates the hybrid grammar of the Ulster dialect:

Múilsha's gather, swúth a múnnaith, múnna-gráha kradyi chúlsha's múnnaik. Gra be grédh'i shedhú ladhu, as aswúth in múnnaith. Búg múilsha thalosk múntrth goshta dhurra; gretul our shakú arak múilsha getyas nidyas grédh'i gamiath múnsha. Njesh solk mwí-l stúth gamiath but bug múilsha achim gamiath. Dhí-íl the srídug, thardyúth and múnnaith. Gradhm a gradhum.

The tinkers believe Shelta to be an independent language of Pictish origin (*The Gypsies*, p. 371). MacRitchie connected this tradition with the fact that Creenie (Cruithnigh) is a Connaught tinker surname and Crink (Cruithneach) a nickname for Irish tinkers (Groome, *In Gypsy Tents*, p. 147). Shelta contributes largely to other English and Irish cant. See *ken* and *gag* (vb) in Harman's *Caveat* (1566), *cín* (Shelta, *ken*) in MacElligott's *Berlagar na saer*, and *tobar* in *Rapparee* (*Ir. rapaire*) cant.

Shemakha, a town of the republic of Azerbaijan, on the Pisargat River, 63 miles W. by N. of Baku, with silk manufactures. It was known to Ptolemy and the Greek geographers as Semachia, and was subsequently for centuries the capital of the Tatar khans of Shirvan, but was entirely destroyed by Nadir Shah in 1742. Nevertheless it was soon rebuilt, but was overwhelmed by an earthquake in 1859, and a second time in 1872. Pop. 20,000.

Shemites. See SEMITES.

Shenandoah, (1) a river of Virginia, drains the beautiful and fertile valley between the Blue Ridge and the principal range of the Alleghanies. It rises in two branches, which unite about 85 miles W. of Washington, and runs north-east 170 miles to the Potomac, at Harper's Ferry. In the war of 1861-65 this valley was the scene of numerous

battles, was successively occupied by the opposing armies, and finally was carried and laid waste by General Sheridan (q.v.) in 1864-65.—(2) A borough of Pennsylvania, 105 miles north-west of Philadelphia. It has a very large trade in anthracite coal. Pop. (chiefly foreign) 25,000.

Shendy, a town in Lower Nubia, on the right bank of the Nile, 100 miles NNE. below Khaitum, with a trade in salt, wool, carpets, ostrich-feathers, &c., and a pop. of about 10,000 (40,000 prior to its destruction by the Egyptians in 1822).

Shenstone, WILLIAM, son of Thomas Shenstone of the Leasowes, Hales Owen, Worcestershire, was born there 18th November 1714. In 1732 he was sent to Pembroke College, Oxford, and whilst there devoted himself much to the study of English poetry. In 1737 he published anonymously a small volume of *Poems upon Various Occasions*; in 1741 *The Judgment of Hercules*; and next year *The School-mistress*, the work by which he is chiefly remembered. In 1745 he succeeded his father in the estate of the Leasowes, where he thenceforth busied himself with landscape-gardening. Such was his success in beautifying his little domain that it attracted visitors from all quarters, and brought him more fame than his poetry, but at the same time involved him in serious pecuniary embarrassments. He died 11th February 1763. *The School-mistress*, which has secured for the 'water-gruel bard' (as Horace Walpole dubbed him) a permanent if humble place among English poets, is written in the Spenserian stanza; and in the contrast between the stateliness of the vehicle and the familiar and homely quality of the subject, with the graphic truth of its treatment, there is a singular source of charm. Shenstone's other works are for the most part quite insignificant; but his *Pastoral Ballad* has touches of exquisite tenderness and truth of sentiment expressed in a simple and appropriate melody.

See *Life* by Dr Johnson prefixed to the pithy *Essays on Men and Manners* (new ed. 1868) and that by George Giffillan to an edition of his *Poems* (Edin. 1854).

Shepherd's Dog. See SHEEP-DOG.

Shepherd's Purse

(*Capsella Bursa-pastoris*), an annual plant of the family Cruciferae, a most abundant weed of roadsides, gardens, and cornfields in Britain, and remarkable as one of the few plants that are found over almost the whole world without the tropics, adapting themselves to almost all soils and climates. It is a very variable plant, from three inches to two feet in height, with root-leaves more or less pinnatifid, all the leaves more or less toothed, and rough with hairs. The root-leaves spread closely along the ground. The flowers are white and diminutive.

Shepherd's Purse
(*Capsella Bursa-pastoris*).

The pouch, from which the English name seems to be derived, is laterally compressed and somewhat heart-shaped. The 'species' has been broken up into a vast complex of elementary species and races, numbering several hundreds.

Sheppard, JACK, born at Stepney in 1702, was the son, grandson, and great-grandson of a carpenter, and himself at twelve, after a year and a half's schooling in Bishopsgate workhouse, was apprenticed to a carpenter in Wych Street, Drury Lane. For six years he did well, but, falling then into bad company, in July 1720 he committed the first of many lobbies. In the course of 1724 he was four times caught, but as often escaped, on the occasion of his third evasion from Newgate forcing six great doors. The fifth time luck deserted him, and on 18th November he was hanged at Tyburn in the presence, it was said, of 200,000 spectators. Harrison Ainsworth made him the hero of a novel (1839). See *Celebrated Trials* (vol. iii. 1825).

Sheppey, ISLE OF, a portion of the county of Kent, insulated from the mainland by the Swale, an arm of the Medway. It is 9 miles long and 4 broad. Once it was larger; but the sea is eating away the north shore, which is lined by cliffs of London Clay 60 to 80 feet high. The church of Minster, formerly in the middle of the island, is now close to the north coast. Almost the whole of the inhabitants are massed in Sheerness (q.v.). In 1732 Hogarth and four others made 'a five days' peregrination' of the island; see their illustrated account (1781, 1782, 1817, &c.).

Shepton Mallet, an ancient market-town of Somersetshire, 15 miles from Bath. It has a market-cross, dating from 1500, 51 feet high; a church with a splendid timber roof; a grammar-school (1627); and some manufactures of silk, velvet, crape, and ale. Pop. 4300.

Sherardising. See GALVANISED IRON.

Sheraton, THOMAS, designer of furniture, was born at Stockton-on-Tees in 1751. In 1791 he produced *The Cabinet-maker and Upholster's Drawing-Book*, with over one hundred plates (new ed. 1793-6-1802; reprinted 1896). He gave his name to a style in which ornament was subordinated to utility, and on severer lines than that of his predecessor Chippendale (q.v.). He died in 1806.

Sherbet, a beverage much used in Mohammedan countries, where stimulating drinks are forbidden. It consists of the juices of various fruits diluted with water, and sweetened.

Sherborne (O.E., 'clear brook'), a pleasant old-fashioned town of Dorsetshire, in the Vale of Blackmore, on a gentle southern hill-slope above the Yeo, 17 miles N. by W. of Dorchester and 5 E. of Yeovil. In 705 Ina, King of Wessex, made it the seat of a bishopric, with St Aldhelm for first bishop, whose twenty-fifth successor, Hermann, in 1075 transferred the see to Sarum. The noble cruciform minster, measuring 207 by 102 feet, with a tower 114 feet high, was the church of a great Benedictine abbey, founded by Bishop Roger in the first half of the 12th century. It was converted from Norman to Perpendicular after a great fire in 1436, and restored in 1848-58. Noteworthy are the clerestory, vaulting, and choir; and in the retrochoir are the graves of Asser and two of King Alfred's brothers. King Edward's School, comprising remains of the abbey buildings, was founded in 1550, reorganised in 1871, and has since risen to be one of the great public schools of England. Sherborne Castle is an Elizabethan mansion, built in 1594 by Raleigh in the grounds of Bishop Roger's Norman castle (c. 1125), which, taken by Fairfax in 1645, is now a ruin. Sherborne has also

a literary institute (1859), Bishop Neville's 15th-century hospital, and the Yeatman memorial hospital (1863), with some manufactures of lace, buttons, and silk. Pop. 6400.

Sherbrooke, a city of Quebec, capital of Sherbrooke county, at the junction of the rapid Magog (with falls) and St Francis rivers, 82 miles E. of Montreal, with many busy factories and large woollen, saw, and flour mills; pop. 23,500.

Sherbrooke, LORD. The Right Hon. Robert Lowe, Viscount Sherbrooke, was born in 1811 at Bingham, Notts, of which parish his father, was rector. He was educated at Winchester, and University College, Oxford, where he became a fellow of Magdalen. Called to the bar, he emigrated in 1842, and soon attained a lucrative practice at the Sydney bar; he also took a leading part in the political life of the colony, ultimately as member for Sydney. At home again in 1850, and returned in 1852 for Kidderminster as an independent member with Conservative tendencies, he in 1853 took office under Lord Aberdeen, and in 1855 under Lord Palmerston. In 1859 he was returned for the borough of Calne by the influence of the Marquis of Lansdowne; and he represented London University from 1868 till he went to the Upper House. During 1859-64 he was vice-president of the Education Board (and virtual minister for Education) in the second Palmerston administration, resigning in 1864, and introduced the Revised Code of 1862, with its principle of 'payment by results.' He largely contributed to ensure the rejection of the Whig Reform Bill in 1866. He was, with other 'Adullamites,' offered a post in the Derby government, but he declined to leave the Liberal party, though in 1867 he was still an opponent of all reduction of the suffrage. In 1868 his feud with the Liberal party was forgotten in the strenuous aid he gave the Liberal leaders in carrying the disestablishment of the Irish Church. Accordingly he obtained in Mr Gladstone's Liberal ministry the office of Chancellor of the Exchequer; exchanging it in 1873 for that of Home Secretary. As Chancellor of the Exchequer, his proposal of a tax on matches was very unpopular; but the annual surpluses were large almost beyond example. He exerted himself to keep down the public expenditure; and his curt treatment of all claimants of public money brought odium upon him. In acuteness and cogency of argument he had hardly an equal. In education he opposed the once exclusive study of the classics. An LL.D. of Edinburgh D.C.L. of Oxford, in 1880 he went to the Upper House as Viscount Sherbrooke. He published a volume of poems (*Poems of a Life*) in 1884; and he died 27th July 1892, at Warlingham, Surrey. See his *Life* by A. Patchett Martin (2 vols. 1893).

Shere Ali. See AFGHANISTAN.

Sheridan, PHILIP HENRY, a brilliant American cavalry commander, was born in Albany, New York, March 6, 1831, third son of John and Mary Sheridan, but a few weeks after the arrival of his Irish parents in the New World. After attending a public school in Ohio, to which state the family removed soon after his birth, he was employed for a time as a shop-boy. In July 1848 he was appointed a cadet at West Point, graduated in 1853, and was appointed a brevet second-lieutenant in the Third Infantry. In May 1861 he was a captain in the Thirteenth Infantry, and in December of that year he was made chief quartermaster of the army in southwestern Missouri. In April 1862 he became chief quartermaster under General Halleck; but in May he was given a regiment of cavalry (the Second Michigan), and, being now in his proper sphere, did such excellent work that he was soon pro-

moted to the command of a brigade, and then to a division of the Army of the Ohio. In the battle of Perryville (8th October), and still more in the battle of Stone River (Murfreesboro'), which ended on 3d January 1863, and where his division lost over 1600 men, he performed brilliant services, and earned his promotion to major-general of volunteers. He took part in the severe battle of Chickamauga, from which field the Northern army fell back within the defences of Chattanooga, and there, serving now under the immediate command of General Grant, he was engaged in all the operations of the campaign that followed, gaining especial credit for the dash and gallantry with which his division drove the enemy up the slope and over the summit of Mission Ridge. Soon afterwards transferred to Virginia, in April 1864 he was given command of all the cavalry of the Army of the Potomac, took part in the battle of the Wilderness, and made a notable raid (May 9-25) on the Confederate lines of communication with Richmond, advancing to the outer defences of that city, cutting railroads, destroying depôts, and on the 11th defeating the enemy's cavalry at Yellow Tavern with the loss of their commander, General Stuart. In the same month he was first into Cold Harbor, and in June took part in the heavy battle there, and fought a number of cavalry actions. In all these his dash and skill attracted Grant's admiration, and in August he placed Sheridan in command of the Army of the Shenandoah, giving him two cavalry divisions commanded by Generals Torbert and Wilson. The task set him was to drive the Confederates out of the Shenandoah Valley and to close this gate into Pennsylvania and Maryland. In September he attacked the enemy under General Early, drove them through and many miles beyond Winchester, and captured 5000 prisoners and 5 guns; and from Fisher's Hill, where Early halted, he again dislodged him, and pursued him through Harrisonburg and Staunton. These battles made him a brigadier-general in the regular army. But Early's army, being largely reinforced by General Lee, again appeared in the Shenandoah Valley, and on October 19, advancing under cover of fog and darkness, succeeded in surprising the Northern army and driving it back in confusion. Sheridan had been in Washington, and at this time was at Winchester, twenty miles away. Hearing the guns, he put his horse to its speed, and arrived on the field by ten o'clock, waving his hat and shouting to the retreating troops, 'Face the other way, boys; we are going back.' His unexpected appearance restored confidence, the lines were re-formed, and a serious defeat was suddenly converted into a great victory. The enemy's left was soon routed, the rest shared their fate, and the Confederates were again, and finally, driven from the valley, which Sheridan, by Grant's orders, now devastated. For Winchester he was promoted to major-general and received the thanks of congress, and Grant's armies fired a salute of 100 guns in honour of the victory.

Henceforward Sheridan fought always under Grant's direct command, and took an active part in the final battles which led to Lee's surrender at Appomattox Court-house, April 9, 1865. His ability as a general was nowhere better displayed than in the action at Dinwiddie Court-house and the assault of Five Forks in March and April, which drove Lee from Petersburg and Richmond. After the war Sheridan was placed in command of the military division of the Gulf, and later of the department of the Missouri. When Grant became president of the United States General Sherman was made general-in-chief and Sheridan promoted to lieutenant-general. In 1870 the latter visited Europe to witness the conduct of the Franco-

German war, and was with Von Moltke during the battle of Gravelotte. On the retirement of Sherman in 1883 he succeeded him as general-in-chief. In May 1888 Sheridan became seriously ill, and a bill was speedily passed by both Houses of Congress restoring for him the full rank and emoluments of general. He died at his country-house in Nonquitt, Massachusetts, August 5, 1888, leaving a widow and three children. He was buried at Arlington, Virginia, within sight of Washington, where a beautiful monument marks his grave.

Sheridan was the nineteenth general-in-chief of the United States army. He never lost a battle, and the confidence and affection which 'Little Phil,' as they delighted to call him, inspired in his troops may be gauged by the story of Winchester. Among the Northern generals he ranks second only to Grant and Sherman. See his *Personal Memoirs* (2 vols. 1888).

Sheridan, RICHARD BRINSLEY BUTLER, was born in Dublin, 30th October 1751. He was the grandson of Swift's friend, Thomas Sheridan, D.D. (1687-1738), and the second son of Thomas Sheridan (1719-88), a man of established reputation as a teacher of elocution, and the author of a now forgotten *Life of Swift*. His mother, Frances Sheridan, née Chamberlaine (1724-66), also had achieved some success in literature, being the author of a novel called *Sidney Biddulph*, and of one or two plays. Richard Sheridan was educated at Harrow, where he does not seem to have distinguished himself much. After leaving school he made his first attempt at literature, in collaboration with a school-friend named Halded, in the form of a three-act farce called *Jupiter*, the general idea of which bears some resemblance to that afterwards worked out in the *Critic*. It does not, however, appear to have ever been completed. The two friends next attempted a verse translation of the *Epistles of Aristonetus*—a pseudo-classical author of unknown date and doubtful identity—of which the first part was published, but attracted no favourable notice. In 1771 the Sheridans settled at Bath, where they made acquaintance with the family of Linley the composer. A sort of sentimental friendship, ripening into a warmer feeling, appears to have been set up almost immediately between Elizabeth Linley, the eldest daughter—a girl of great beauty and musical talent, popularly known as the Maid of Bath—and Richard Sheridan, which, after various romantic episodes, terminated in a marriage, with the rather reluctant consent of the parents in 1773.

The young couple settled down in London to a life considerably beyond their means. Mrs Sheridan had a fortune in her voice, but her husband would not allow her to use it professionally. He himself now made more serious efforts at dramatic composition—which had always attracted him—and got a play accepted at Covent Garden. On the 17th of January 1775 the *Rivals* was produced for the first time with no great success; but after a slight alteration in the cast the play met with universal approval. Probably it will always remain the most popular of Sheridan's performances. There is nothing in it to strain the understanding or require any education of mind to comprehend. Nor does it contain the least touch of bitterness; vices are not satirised, but only oddities laughed at. Above all, the plot is clear and connected, a point by which the ordinary playgoer is naturally apt to judge. It is not too much to say that in genuine mirthful humour Sheridan has been surpassed by Shakespeare alone; and this quality predominates in the *Rivals*. In the same year appeared the farce called *St Patrick's Day*—a poor performance which Sheridan wrote for the benefit of

the Irish actor whose personation of Sir Lucius had saved the *Rivals*—and also the *Duenna*, which received an exaggerated meed of praise, and had a (then) phenomenal run of sixty-three nights. In 1776 Sheridan, with the aid of his father-in-law, Linley, and another friend, bought half the patent of Drury Lane Theatre for £35,000 from Garrick, who was retiring from the stage, and some years later the remaining share for £45,000 from Mr Willoughby Lacy, thus becoming complete owner. His first production here was a purified edition of Vanbrugh's *Relapse*, under the title of a *Trip to Scarborough*, while three months later appeared his greatest work, the *School for Scandal*. As a dramatic composition the *School* is inferior to the *Rivals*; the plot is involved and its details obscure, the play a series of extraordinarily brilliant scenes, but wanting in cohesion. So powerful is the satire, however, and so real and striking are the characters, that Sheridan's contempt for the dramatic unities has never diminished the enthusiastic approval awarded to it from the first. It brought back prosperity for a time to Drury Lane, where Sheridan's idle and careless management had done much mischief. In 1779 he produced the *Critic*, a play of even more heedless composition than the *School for Scandal*, but teeming from end to end with a sparkling wit which carries it over all obstacles. This was Sheridan's last dramatic effort, with the exception of a tragedy called *Pizarro*—in no respect superior to Mr Puff's tragedy—prepared for the stage by him some twenty years later.

Sheridan now began to turn his thoughts to another field for ambition, and on the dissolution of parliament in 1780 he was elected member for Stafford. He adhered to the opposition, then under the leadership of Burke and Fox, and on the change of government in 1782 became under-secretary for foreign affairs under Rockingham, afterwards serving as secretary to the Treasury in the coalition ministry (1783). His parliamentary reputation, however, may be said to date from the impeachment of Warren Hastings. His part in the attack was to expose the connivance at the plundering of the Begums of Oudh, on which subject he delivered three great speeches. The first, in the House of Commons, was a marvel of oratory, and produced such an effect upon the audience that the House decided to adjourn, as being still too much under the influence of this wonderful speech to give a cool, impartial vote. The second, on the actual trial of Hastings, was rather less successful, and the answer to the pleadings of Hastings' counsel, seven years later, was, comparatively speaking, a failure. The reputation thus acquired was not sustained, his habitual indolence perhaps rendering him incapable of a continued effort. During the thirty-two years he sat in parliament Sheridan took an active part in the debates, and was known as a lively and occasionally impassioned speaker. In 1794 he again electrified the House by a magnificent oration in reply to Lord Mornington's denunciation of the French Revolution, but with this exception he never again rose to the same height. At the critical period of the mutiny at the Nore he did much to strengthen the hands of the government by his unselfish and patriotic support. He remained the devoted friend and adherent of Fox till the latter's death, and was also the defender and occasional mouthpiece of the Prince Regent. Few rewards fell to his share. In 1806 he was appointed Receiver of the Duchy of Cornwall, and in 1806 held for a short time the small post of treasurer to the navy. In 1812 he was defeated at the polls at Westminster, and his parliamentary career came to an end.

To turn to his private life. In 1792 his first wife,

to whom he had been passionately attached, though he must at times have caused her great unhappiness, died; and three years later he married again a Miss Ogle, daughter of the Dean of Winchester, who survived him. The affairs of the theatre had gone badly. The old building had to be closed as unfit to hold large audiences, and a new one built which was opened in 1794, but this also was destroyed by fire in 1809. This last calamity put the finishing touch to Sheridan's pecuniary difficulties, which had long been serious. Misfortunes gathered thick upon him, and his latter days were spent in trouble and privation. He died on the 7th July 1816 in great poverty, with bailiffs actually in possession of his house; but the friends of his prosperity came forward to give him a magnificent funeral in Westminster Abbey.

See the Memoirs prefixed to editions of his works by Leigh Hunt (1840), James P. Browne (2 vols. 1873-75), and Stainforth (1874); Lives by Watkins (2 vols. 1817) and Moore (2 vols. 1825); *Sheridan and his Times* (2 vols. 1859); *Memoirs of Mrs Frances Sheridan*, by her granddaughter, Alicia Le Fann (1824); W. Fraser Rae, *Wilkes, Sheridan, and Fox* (1874); the short Life by Mrs Olphand (1883); Percy Fitzgerald, *Lives of the Sheridans* (2 vols. 1887); Lloyd C. Sanders, *Sheridan* (1891); and the Lives by Fraser Rae (2 vols. 1896) and W. Sichel (2 vols. 1909). The edition by L. O. Williams (1926) is the accepted text of his dramatic works. See also NORTON (MRS).

Sherif, or **SHEREEF**, designates a descendant of Mohammed through his daughter Fatima and Ali. The title is inherited both from the paternal and the maternal side; and thus the number of members of this aristocracy is very large among the Moslems. The men have the privilege of wearing green turbans, the women green veils, green being the prophet's colour. Many of these sherifs founded dynasties in Africa: the line which reigns in Morocco (q.v.) boasts of that proud designation. The ruling princes of the district of Mecca and guardians of the Kaaba (q.v.) have been called grand sherif for the sake of distinction.

Sheriff (O.E. *scir-gerfa*, the reeve or fiscal-officer of a shire), in English law, is an officer whose duties are chiefly ministerial (for he has only a few trifling judicial duties). The office is of great antiquity. The sheriff was (next to the ealdorman or earl, and the bishop) the chief man of the shire, and seems to have possessed unlimited jurisdiction to keep the peace; to have presided in the courts of the shire; to have punished all crimes, and have redressed all civil wrongs. The sheriff was formerly chosen by the inhabitants, though probably requiring confirmation by the crown. But popular elections for that purpose were put an end to by a statute of 9 Ed. II., which enacted that in future the sheriffs should be assigned by the chancellor, treasurer, and judges. Ever since that statute the custom has been, and now is, for the judges, the Lord Chancellor, and Chancellor of the Exchequer to meet in the Court of Exchequer (now the King's or Queen's Division) on the morrow of St Martin (12th November), and there propose three persons for each county to the crown. On the morrow of the Purification (3d February) the names are finally determined on, the first on the list being generally chosen; and the sovereign afterwards 'pricks off' the person selected, by piercing the list with a punch opposite his name, and so appoints him to the office. A sheriff continues in office for one year only, and cannot be compelled to serve a second time. The office is not only gratuitous, but compulsory, for if the person appointed refuses he is liable to be fined. In practice, country gentlemen of wealth are appointed. As military head of the county the sheriff was superseded by the Lord-lieutenant

(q.v.) as early as the reign of Henry VIII. In the city of London the sheriffs are appointed not by the crown, but by the citizens. The sheriff has important official duties in elections of members of parliament. He is, by his office, the first man in the county, and superior to any nobleman while he holds office. He has the duty of summoning the *posse comitatus*—i.e. all the people of the county—to assist him in the keeping of the peace; and if any person above the age of fifteen, and under the degree of a peer, refuse to attend the sheriff after due warning, he incurs a fine or imprisonment. The chief legal duty which the sheriff discharges is that of executing—i.e. carrying out—all the judgments and orders of the courts of law. It is he who seizes the goods of debtors or their persons, and puts them in prison. For this purpose he has a number of persons called bound-bailiffs (or, in popular dialect, bumbailiffs), who in practice do this invidious work, and give a bond to the sheriff to protect him against any mistake or irregularity on their part. The necessity of this bond is obvious, for the doctrine of law is that the sheriff is personally responsible for every mistake or excess made or committed by the bailiffs in executing the writs or process of the court; actions may be brought against him by indignant prisoners, or debtors whose persons or goods have been arrested; and the courts watch jealously the least infringement of personal rights caused by these bailiffs. Every sheriff ('high-sheriff') has an under-sheriff, usually a solicitor, who takes charge of the legal business; and he is required to name a deputy in London to whom writs may be delivered.

The sheriff's extensive jurisdiction, gradually acquired at the cost of local courts, has been gradually infringed upon, partly by the exercise of the royal prerogative, and partly by parliament. But in England it suffered more from the appointment to the office of men not specially qualified to exercise judicial powers, and from the consequent usurpation of their functions by the supreme courts. The same causes operated in Scotland, though to a less extent. In England they resulted in the almost entire abolition of the judicial functions of the sheriff. In Scotland they resulted in his being deprived of the more important parts of the criminal jurisdiction, particularly of the power to punish by death, and in his civil jurisdiction being limited mainly to questions affecting movables. In both countries the office was entrusted to gentlemen having estates in the county; in some cases it was hereditary; these arrangements tended to a separation of the duties of the office into the honorary and the laborious—the former being performed by the sheriff, and the latter by his deputy. In Scotland this separation was completed by the act of Geo. II., which entirely separated the offices by the transference of the power of appointing the depute from the principal sheriff to the crown. In England this complete separation has never become necessary, from the fact of the sheriff's power having been much more crippled than in Scotland. Indeed, in England, so purely honorary and ministerial has the office become, that it has been held by a female, and in Westmorland the office was hereditary down to 1849. The duty of enforcing the orders of the supreme courts, which now in England is a principal part of the duties of the sheriff, appears to have been engrafted on the office—probably on the theory that these orders were those of the king himself. In Scotland the sheriff has never been called on to enforce any writs except those actually and not merely in name proceeding at the instance of the crown.

SHERIFF, in Scotland, is a title given to the magistrate and judge of a county. In Scotland the office of sheriff is still that of a local judge,

and not merely ministerial, as in England; and the jurisdiction, both civil and criminal, is still very extensive. The duties of the office are now performed by two officials, the sheriff and the sheriff-substitute. The term 'depute,' often used since the abolition of the Heritable Jurisdiction (q.v.) to distinguish the sheriff from the sheriff-substitute, is inappropriate and obsolete. The title of sheriff-principal was until the Sheriff Court Act of 1907 the popular and the correct legal designation of the sheriff, but that act, while it does not in terms abolish the title, uses throughout the title of sheriff. The sheriff, except in the case of Edinburgh and Glasgow, does not reside in the county, but holds courts therein at stated periods. The sheriff is disqualified from acting as advocate in any cause originating in his county, though in other respects he is at full liberty to practise. He is appointed by the crown exercised on the recommendation of the Secretary of State for Scotland. He must either be an advocate of at least five years' standing or, if not an advocate, he must have occupied the position of salaried sheriff-substitute for at least five years preceding the date of his appointment. He holds his office for life or good behaviour, but he can be removed by the Secretary of State for Scotland upon a report by the Lord President of the Court of Session and the Lord Justice-clerk, which must be before both Houses of Parliament for four weeks while parliament is sitting. The sheriff-substitute was at first appointed by the sheriff, but he is now appointed by the crown, requires to be an advocate of five years' standing or a duly qualified law agent of a similar standing in his profession. His tenure of office is, like that of the sheriff, *ad vitam aut culpam*. He may, however, be removed from office by the Secretary of State for Scotland, upon the report of the Lord President and the Lord Justice-clerk, for inability or misbehaviour. He resides within the county, and presides over the ordinary sittings of the court. The civil jurisdiction of the sheriff extends to all personal actions on contract or obligations without limit, actions for rent, and other questions between landlord and tenant, and actions by employers against employees. His powers are limited in matters of heritable right and title to cases where the value does not exceed £1000, or £50 by the year. He can, however, adjudicate on questions of possession beyond these limits, and he can also deal with questions of servitude and nuisance. He cannot decide questions of status, but he may entertain questions of aliment. There are various other matters with which the sheriff may deal, such as questions of poor-law, lunacy, elections, &c. Besides his ordinary court the sheriff holds the Small Debt Court, which is a statutory court for actions which do not exceed £20 in value, or which have been restricted to that amount. This court is made great use of by all classes of the community. The Debts Recovery Court was abolished by the Act of 1907 (*supra*). The civil proceedings in the Sheriff Court also include the 'summary cause,' which was the creation of the Act of 1907 (*supra*). That statute introduced a special form of procedure for cases of small importance, which is informal and reduces the costs of litigation. The term 'summary cause' includes actions for payment of money not exceeding £50 in amount, exclusive of interest and expenses, with the exception of actions brought in the Small Debt Court and claims under the Workmen's Compensation Act. The sheriff has also jurisdiction in cases of bankruptcy and insolvency. Against most judgments in ordinary cases by the sheriff-substitute there lies an appeal to the sheriff, and in some cases to the Court of Session. In criminal cases the sheriff has jurisdiction in all the

minor offences which do not infer death or banishment, but his powers of punishment are practically limited to imposing a sentence of not more than two years' imprisonment. The forms of trial in use before the sheriff are jury trial and cases which are brought under the Summary Jurisdiction Acts. Changes of considerable importance, and in many of the details of criminal procedure, were introduced by the Criminal Procedure (Scotland) Act, 1887. The sheriff's jurisdiction excludes that of the justices of peace in riots. He is occasionally consulted by the procurators-fiscal in difficult cases, and the sheriff-substitute is occasionally called in to superintend criminal precognitions. He returns the writs for the election of members of parliament, and this duty is almost the only one which he performs in common with the English sheriff. An idea of the multifarious duties performed by the Scottish sheriff may be gathered from the statement that he exercises somewhat similar functions to those which in England are exercised by the commissioners in bankruptcy, county-court judges, the stipendiary magistrates, recorders, and coroners. The office of Commissary (q.v.) has been amalgamated with that of sheriff. Additions to the miscellaneous duties of the Scottish sheriffs are not infrequently made in the course of legislation. See COUNTY.

The sheriff-clerk, in Scotland, is the registrar of the sheriff's court, and as such has charge of the records of the court. He registers, and, when required by the proper party, issues the sheriff's judgments. He also conducts what correspondence may be required. He has important duties to perform in regulating the summary execution which is issued in Scotland against the debtors in bills of exchange, promissory notes, and bonds. See J. D. Wilson, *Practice of the Sheriff Courts of Scotland*; W. J. Lewis, *Sheriff Court Practice* (1923); and Sheriff Courts (Scotland) Act, 1907, as amended by the Sheriff Courts Act, 1913.

In the United States the office of sheriff is mainly ministerial; the principal duties being to maintain peace and order, to attend courts as administrative officer, to guard prisoners and juries, to serve processes and execute the judgments of the courts, and to preside at inquisitions. In most of the states the sheriff is appointed by the popular vote, and the shrievalty in such places as New York is a highly paid and highly coveted political office. In all the states there are deputy-sheriffs, who are the servants and agents of the sheriff; and in some of the states there is an under-sheriff, who does duty for the sheriff in his absence.

Sheriffmuir, in Perthshire, on the northern slope of the Ochils, 2½ miles ENE. of Dunblane, was the scene, on 13th November 1715, of an indecisive battle between 8400 Jacobites under the Earl of Mar and 3500 Hanoverians under the Duke of Argyll. The Macdonalds, who formed the centre and right of the Highland army, completely routed the left of their opponents; but Argyll with his dragoons had meantime driven the left of the Highlanders back for two miles. About 500 fell on each side.

Sherlock, WILLIAM, was born in Southwark in 1641, had his education at Eton and Peterhouse, Cambridge, and became Rector of St George's, Botolph Lane, London, in 1669. Later he was preferred to be prebendary of St Paul's, Master of the Temple, Rector of Therfield in Herts, and Dean of St Paul's (1691). At the Revolution he refused at first to take the oath, but soon complied. He died at Hampstead in 1707. He wrote about sixty books or pamphlets, mostly controversial. His *Practical Discourse Concerning Death* (1689) was long famous, and was styled by Addison 'one of

the strongest Persuatives to a Religious Life that ever was written in any language.' The *Vindication of the Doctrine of the Trinity and of the Incarnation* (1690) opened up a fierce and unseemly controversy with South (q.v.) and others, which is said to have been closed only by the express desire of the king. Sherlock attempted to explain the relations of the three Persons by 'a mutual self-consciousness,' but his metaphysical powers were not subtle enough for his task, and he cannot be said to be altogether undeserving of South's charge of Tritheism. His *Case of Allegiance to Sovereign Powers Stated* (1691) was published to justify his own swallowing of the oath, and at once excited a raging controversy. Other works discussed Future Judgment (1692) and Future Punishment (1704-5), but these have long lost their importance.

His son, THOMAS SHERLOCK, was born in London in 1678, educated at Eton and Catharine Hall, Cambridge, and in 1704 succeeded his father as Master of the Temple. In 1715 he became Dean of Chichester, in 1728 Bishop of Bangor, in 1734 of Salisbury, and in 1748 of London. He died in 1761. Sherlock was a strenuous Tory, yet so much of an observer of the times as to earn Bentley's nickname of Cardinal Alberoni. His volumes of Temple Sermons were highly praised in their day, and the Rev. T. S. Hughes edited his complete writings, including treatises against Hoadly, on prophecy, the *Trial of the Witnesses* for the resurrection, &c. (5 vols. 1830).

Sherman, capital of Grayson county, Texas, 64 miles by rail N. of Dallas, contains a fine courthouse and jail, has foundries and mills, is in a farming and stock-raising district, and is a depot for grain and cotton. It has several colleges, three of them for women. Pop. 15,000

Sherman, WILLIAM TECUMSEH, eighteenth general-in-chief of the United States army, was born in Lancaster, Ohio, February 8, 1820, the sixth son of Judge Sherman, who died when William was nine years old. He attended school in Lancaster until 1836, then was appointed to a cadetship at West Point, and graduated in July 1840 sixth in a class of forty-two. He was commissioned second-lieutenant in the Third Artillery and ordered to Florida, where there was some trouble with the Seminole Indians, and was afterwards stationed at Fort Morgan and Fort Moultrie, and from 1846 to 1850 in California. Seeing no prospect of promotion Sherman resigned from the army in 1853, having previously married Miss Ellen Boyle Ewing, daughter of Thomas Ewing, secretary of the Interior, and entered civil life. He was a banker in San Francisco for several years, and at the beginning of the civil war was superintendent of the Louisiana Military Academy at Alexandria, which position he immediately resigned. In May 1861 Sherman was commissioned colonel of the Thirtieth Infantry, and joined his regiment at Washington. In the battle of Bull Run he commanded a brigade, and for good conduct in that engagement was promoted to brigadier-general of volunteers. Sherman was one of the first to estimate properly the serious nature of the struggle before the country. In August he was sent to Kentucky, but when he asked for 200,000 men to put an end to the war in that section, the authorities at Washington looked on his demand as wildly extravagant, if not insane, and deprived him of his command. But soon after he was given a division in the Army of the Tennessee, and in April 1862 displayed both coolness and skill in the severe two days' battle of Shiloh, where he was wounded, but would not leave the field. Grant afterwards wrote: 'To his individual efforts I am indebted for the success of that battle.' In May

he was made a major-general of volunteers, and stationed at Memphis.

In the various movements made by General Grant against Vicksburg Sherman was most active, commanding the famous Fifteenth Corps of the Army of the Tennessee, and being next in rank to Grant. Immediately after the surrender of that Confederate stronghold, July 4, 1863 (the date of his brigadiership in the regular army), he moved against General J. E. Johnston at Jackson, Mississippi, and drove him out of that city. In November Sherman joined Grant at Chattanooga, and rendered excellent service in the great victory won there on the 25th, withstanding a long series of attacks intended to crush his command; and a few days later he hurried to relieve Burnside, besieged at Knoxville by General Longstreet, whose forces fled at the approach of the Northern cavalry. On 12th March 1864, the same day that Grant became commander-in-chief, he appointed Sherman to the command of the south-west, with headquarters at Nashville. In April he commenced his campaign against Atlanta, his command consisting of the armies of the Cumberland, Ohio, and Tennessee, in all about 100,000 men, with 254 guns. Moving from Chattanooga Sherman first encountered General Johnston at Dalton, May 14, and, by repeatedly turning his position and constantly pursuing and pressing him, drove him to Cassville and beyond the Etowah, thence to a strong position on Kennesaw Mountain (where the Union army was at first heavily repulsed), and finally to Atlanta, the direct attack on which began on July 17. Many bold sorties were made by General John B. Hood, who had superseded General Johnston, and fierce encounters occurred at Peach Tree Creek, Ezra Church, and elsewhere, all unfavourable to the Confederates, until on 1st September they evacuated the city, and Atlanta was won.

After giving his gallant army a rest Sherman moved out of Atlanta on his famous march to the sea, with about 65,000 men. Passing between Augusta and Macon, and meeting with little serious opposition, for Hood and his army had been disastrously defeated by General Thomas in the battle fought near Nashville, he reached the outworks of Savannah on December 10—a march of 300 miles in twenty-four days, with a loss of 63 killed and 245 wounded. The works were soon carried, and on the 20th General Hardie evacuated the city, Sherman marching in on the 21st. To President Lincoln he wrote: 'I beg to present you as a Christmas gift the city of Savannah, with 150 guns, plenty of ammunition, and 25,000 bales of cotton.' For his great services he had already been made a major-general in the regular army, and now he received the thanks of congress for his 'triumphal march.'

Early in February Sherman and his army left Savannah for the north, and by the 17th, compelling, by another flanking movement, the evacuation of Charleston, he had reached Columbia, the capital of South Carolina. Thence he moved on Goldsboro' by way of Cheraw and Fayetteville, fighting by the way severe battles at Averysboro' and Bentonville in March, and aiming either to cut off Lee's retreat or to join Grant before Richmond. But on April 9 Lee surrendered, and word of this coming to General Johnston, he made terms with Sherman on the 17th, which, however, were disapproved as too lenient by Secretary Stanton and repudiated: Lincoln had been assassinated on the 14th. The surrender of Johnston's army was soon followed by all the other Confederate forces then in the field, and the four years' war was at an end.

Before the disbandment of Sherman's army and the Army of the Potomac, they passed in review at Washington before President Johnson and General

Grant on May 23 and 24, 1865. Sherman took leave of his troops in a field order of May 30. For the four years following he was in command of the division of the Mississippi; and when Grant became president Sherman succeeded to the head of the army with the rank of general, having been previously promoted to lieutenant-general. In 1872 he visited Europe, everywhere receiving distinguished honours; and in 1874, at his own request, to make room for Sheridan, he was retired on full pay. His remaining years were spent in St Louis and in New York, where he died February 14, 1891. He received a public funeral in both these cities, and was buried by the side of his wife and favourite son William in the St Louis Cemetery. Many lives have been published of Sherman, but much the most valuable are his own Memoirs, first issued in two vols. in 1875, and of which revised editions were published in 1885 and 1891. A noble equestrian statue of Sherman adorns New York City.

JOHN SHERMAN, senator, a younger brother, was born at Lancaster, 10th May 1823, was for a time attached as rodman to a corps of engineers, and then studied law with his brother Charles, whose partner he became after his admission to the bar in 1844. From 1855 to 1861 he sat in congress, from 1859 as chairman of the committee of ways and means; and in the senate, of which he was a member from 1861 to 1877, he was for many years chairman of the committee on finance. As a congressman he had been eminent for the steady but statesmanlike opposition which he offered to slavery, and on the outbreak of the war he raised a brigade in Ohio largely at his own expense. Two bills for which he was largely responsible were that for the reconstruction of the seceded states and that providing for the resumption of specie payment (1879). A supporter of Hayes, he was appointed by him in 1877 Secretary of the Treasury, and in 1878 had prepared such a redemption fund in gold as speedily raised the legal-tender notes to par value. In 1881 and 1887 he was again returned to the senate, was for a while its president, and afterwards chairman of the committee on foreign relations. In 1880-84-88 he was a popular Republican candidate for the presidency. The Sherman Act (1890), authorising large purchases of silver by the Treasury, was repealed in 1893. In 1897 he was made Secretary of State by McKinley; but, becoming infirm, he retired from public life in April 1898. He died at Washington, 22d October 1900. See Life by Bronson (1880), his *Selected Speeches on Finance and Taxation* (1879), and the *Sherman Letters* (1894).

Sherrington, SIR CHARLES SCOTT, physiologist, born in London, 29th November 1859, passed through Caius College, Cambridge, and became Brown professor of pathology in the University of London. Later he taught physiology in St Thomas's Hospital, London, the University of Liverpool (1895-1913), the Royal Institution (1914-17), and became Waynflete professor of physiology at Oxford. His researches in the field of nerve physiology, more particularly his formulation of the general principles of reflex action, and his able statement of his discoveries in *The Integrative Action of the Nervous System* (1906; based on the Silliman Memorial Lectures delivered by him at Yale in 1904), have gained him an international reputation. Among the very numerous honours which have fallen to him are the Royal Medal of the Royal Society, the Baly Medal of the Royal College of Physicians, the Retzius Medal of the Royal Swedish Academy, membership of many British and foreign learned societies, honorary degrees of universities at home and abroad, the presidency of the physiological section of the

British Association (1904), the presidency of the Royal Society (1920-25), and his creation as G.B.E. in 1922.

Sherry, a name derived from Xeres (q.v.), or Jerez de la Frontera, near Cádiz, and applied to the better kind of white wines grown over a considerable area in the neighbourhood of Xeres, between the mouths of the Guadalquivir and Guadalete. Sherries may be divided into the Amontillado class and the Montilla—the latter the lighter and dryer, with grape spirit added only when it is required to enable the wine to stand transport. The Amontillados are generally fortified so that sherry of this type contains about 32 degrees of proof spirit. So-called 'natural sherry' has from 2 to 4 per cent. of spirit added to make it keep. Sherries are coloured by introducing wine boiled down to a liqueur, and sweetened by mixing with them wine made from over-ripe grapes. The trade is largely in the hands of Englishmen settled at Xeres: Cádiz is the chief shipping port, and the export is mainly to England. See SACK, WINE.

Sherwood Forest, a stretch of hilly country in the west of Nottinghamshire, lying between Nottingham and Worksop, and extending about 25 miles from north to south and 6 to 8 miles from east to west. It was formerly a royal forest, and the traditional scene of many of the exploits of the famous Robin Hood (q.v.); but it is now almost wholly disafforested, and is occupied by fine parks. The town of Mansfield and a number of villages are situated within the ancient bounds. Numerous remains of the old forest are still to be seen. Railway developments in 1925 threatened to spoil the amenities of the forest.

Shetland, or ZETLAND (Scand. *Hjaltland*, 'high land'), a group of more than a hundred islands, islets, and skerries, forming the northernmost Scottish county, whose capital, Lerwick, is

sq. m., the largest of the twenty-seven inhabited islands being Mainland (378 sq. m.), Yell (83), Unst (47), Fetlar, Bressay, Whalsay, and Foula. The cliff-scenery is very fine, and the sounds and voes, or fiths, are so numerous that no spot is more than 3 miles from the sea. The surface is more rugged than that of Orkney, the highest points being Ronas Hill (1475 feet) in Mainland, and the Sneng (1372) in Foula. Metamorphic crystalline rocks predominate, with isolated Old Red Sandstone; and the soil is peaty, barely one-sixth of the total area being in cultivation, whilst trees there are none. The live-stock includes, besides sheep and cattle, many shaggy 'Shetland ponies,' 9 to 10 hands high. The climate is equable but moist (rainfall, 49 inches); at the longest day the sun sets for only five hours, at the shortest for over eighteen. The herring and other fisheries are the leading industry, having been greatly developed since 1872. Shetland unites with Orkney to return one member to parliament; but it was dissevered therefrom as a county by the Local Government (Scotland) Act, 1889. Pop. (1801) 22,379; (1861) 31,679; (1921) 25,520. Subject, like Orkney (q.v.), to the Scandinavian crown until 1468, Shetland is still markedly Norse in many of its characteristics, Norse being still spoken in Foula as late as 1774, and having bequeathed many words to the Shetland dialect. In 1766 it was sold by the Earl of Morton to the ancestor of the Earls of Zetland, but the present earl's property here is small.

See LERWICK, FOULA, BROCH, CROFTERS, and for the old Udal tenures, ALLODUM; Scott's *Private*, Tudor's *Orkneys and Shetland* (1883); books by Brand (1701), Rampini (1884), J. Russell (1887), and for dialect Edmondston (1866), Jakobsen (1897, 1909), and Angus (1914).

Shevchenko, TARÁS, Ukrainian lyric poet born in serfdom near the Dnieper in 1814. In his youth he was in turn a sexton's apprentice, a shepherd, a wandering artist, a scullion, a page, and a decorator's apprentice, his travels leading him from his own village of Kirillovka first to Poland then to St Petersburg. His flair for drawing brought him friends in the St Petersburg Academy of Arts, the director himself redeeming him from serfdom. He studied art at the academy, and became art lecturer at Kiev university in 1847. In 1840 and 1842 he published volumes of verse in the Ruthenian dialect, which by their simplicity and directness won the admiration of the peasant folk of his homeland. But in 1848 he was accused of seditious writing and drawing, and spent ten miserable years in military penal servitude mostly in the salt deserts of the Caspian district. There any writing or drawing had to be done surreptitiously. His intellect was blighted, and when he was released in 1858 he was both mentally and physically wrecked. Some of his poems written during the early years of exile were lost, but a gem of lyric art remains in *Winter*, a poem written a month before his death, which took place 26th February 1861. He was buried beside the Dnieper. See E. L. Voynich's translation of *Six Lyrics* (1911).

Shiahs. SHITES.

Shibboleth (properly *Shibbo'leth*, Heb., 'ear of corn,' or 'stream'), the test-word used by the Gileadites under Jephthah after their victory over the Ephraimites, recorded in Judges, xii. 6. The latter could not pronounce the *sh*, and, by saying sibboleth, betrayed themselves, and were slaughtered at the ford. All those Hebrew names in the Old Testament which commence with the *sh* have now, through the inability of the Septuagint to render this sound in Greek, become familiar to us, through the versions that flowed from it, as beginning with the simple *s*—e.g. Simon, Samaria, Solomon, Saul,

116 miles N.E. of Kirkwall, 300 N. by E. of Edinburgh, and 222 W. of Bergen in Norway (direct distance). Extending 70 miles in length, and 36 in extreme breadth, they have a total area of 551

&c. The word Shibboleth is still used to mean a test of opinions and manners.

Shiel, Loch, a fresh-water lake in the west of Scotland, on the boundary between Moidart in Inverness-shire and Ardgour in Argyllshire, 18 miles W. of Fort-William. It extends $17\frac{1}{2}$ miles south-westward, is 1 mile broad, is overhung by mountains nearly 3000 feet high, abounds in fish, and communicates with the sea by the river Shiel and salt-water Loch Moidart. Prince Charles Edward was here, a fugitive, in 1746; and Queen Victoria in 1873. At the head is Glenfinnan (q.v.).

Shield, a portion of defensive armour held in the left hand or worn on the left arm to ward off sword-strokes or missiles. The earliest known shields date from the close of the bronze age. They are circular and flat, or but slightly convex, with a central boss, under and across which the handle is fixed. The material is thin beaten bronze, strengthened by a turned-over rim round the circumference, and by the surface being embossed with concentric circles alternating with circular rows of small bosses. The Greek shield of the Homeric period was also of bronze, circular, convex, and often ornamented with devices. The Etruscan shield of bronze, of which there is a fine specimen in the British Museum, is also circular and ornamented in concentric bands of embossed work round the central boss. The Roman infantry used a light round shield about three feet in diameter, and the cavalry carried a smaller buckler also of a round form covered with hide, while the spearmen had a large oblong convex shield of wood and leather strengthened with iron, which covered the whole body. The early Germanic shields were also large, oblong, and convex, and Tacitus, in the 1st century of our era, mentions that they were painted with gay colours and devices. These are supposed to have been the precursors of the heraldic devices on the shields of the middle ages. From the downfall of the Roman empire to the 10th and 11th centuries there seems to have been considerable variety in the forms of the shields in use among European nations, though the circular shield was perhaps the most common. The shields of the Anglo-Saxon invaders of England and of the Scandinavian vikings were mostly circular. But the Norman shield of the 11th century was kite-shaped (see **BAYEUX TAPESTRY**), and the triangular form continued to prevail till the 15th century, becoming gradually shorter and more obtusely pointed, or heater-shaped. After the 14th century the small round buckler came into fashion, and retained its place till the 16th century. By this time the use of firearms had made the shield practically useless in warfare. The large shields used at tournaments and pageant shields and bucklers were often highly ornamented, some of the latter being among the most beautiful works of art of the middle ages. Round shields or *targets*, covered with hide or leather, ornamented with brass studs and bosses, were used in the Highlands of Scotland down to 1745. Many savage tribes still use shields of wood or hide of various forms. For the heraldic shields, see **HERALDRY**.

Shield, William (1748-1829), composer, was born in Durham, and early became a violinist and violist at Scarborough and London. He was appointed composer to Covent Garden (1778-97) and Master of the King's Musicians (1817-29). He wrote about forty stage pieces, also two textbooks on harmony.

Shields, North, is now part of the burgh of Tynemouth (q.v.).

Shields, South. See **SOUTH SHIELDS**.

Shigatze, or **DIGARCHI**, a town of Tibet, stands near the left bank of the Nyang-chu near its

confluence with the Brahmaputra, 140 miles W. by S. of Lhasa, at an altitude of over 12,000 feet. Near by is the great monastery of the Tashi-lunpo, the residence of the Tashi-Lama. Pop. of Shigatze, 9000. See Hedin, *Trans-Himalaya* (1909).

Shih-wei. See **MONGOLS**.

Shītes (also *Sheeahs*; 'sectaries,' from the Arab. *shāh*, 'a party'), the name given by orthodox Muslims or Sunnites to Ali's followers, who call themselves *al-adeliyyah*, 'the right people.' They were the champions of Ali's right to be Mohammed's successor as being his cousin and son-in-law (see **KHALIF, ALI**); and after Ali's death they took the side of his sons Hassan (Hasan), Hussein (Hosain), and Mohammed ibn al-Hanafīyyah. The Persians, believers in the divine right and even in the divine nature of kings, took this side. All Shītes allegorise the Koran; but the ultra-Shītes, founded by Abdallāh ibn Sabā, a converted Jew of Yemen, differed from the moderate Shītes or Zaidites in believing in the transmigration of souls, and in calling Ali and his legitimate successors incarnations of God. By Shīte help the Abbāsides in 750 wrested the khalīfate from the Omīyades. Yet, unsound as the Abbāsides were, and decided as Persian ascendancy was for 100 years, the Shītes gained little. They were the strength of 'the veiled prophet' (see **MOKANNA**) in 770-779 and of Bālek 817-837. Their disaffection was one chief reason for the introduction of Turks into the khalīf's service (830-840). In 765 the death of Jaafar the Veracious, the sixth Shīte Imām, developed the Ismaīlī sect of the Shītes. Those followed the eldest son Ismael; the majority, following Moosā the second son, were afterwards named *Twelvers*, the series of their Imāms ending with the twelfth. In 'Iraq in 887 arose the Karmathian branch of the Ismaīlīs. In 909 an Ismaīlī proclaimed himself in North Africa as the first Fātimide khalīf. The 6th khalīf of this line, Hākim, was declared to be God's tenth and final incarnation by Darazī, who founded the sect of the Druses. In 1090 Hassan Sabbāh, an Ismaīlī of Khorasān, as the Sheikh of the Mountains instituted the order of Assassins, who generally recognised the Fātimide khalīfate. Ismaīlīs are still found in Persia and Syria. The moderate Shīsm that has been the national religion of Persia since the native royal line of Saffīdes ascended the throne in 1499 is more Koranic than Sunnism. It has Hadīth and Sunna (see **SUNNITES**), but not those of the orthodox Muslims. It has its own modes of religious washing, and its own postures in prayer. Shītes, habitually ill-used in Arabia, absent themselves much from Mecca, and, unable to bless Abu-bekr and Omar, who are buried in Medina, go still less thither. But they do pilgrimage unhindered to the tombs of Ali and Hussein in the province of Bagdad, and to the tomb of Rīza, one of their twelve imāms, in Meshhed, and to the tombs of Shīte saints. They keep the orthodox feasts and others, among which the Moharram feast, occupying the first ten days of the month of Moharram (q.v.), and commemorating the martyrdom of Hussein, is the chief. (For the Shīte cry of *Ya Hasan! Ya Hosain*, see **HOBSON-JOBSON**.) They detest Ayesha and the founders of the four orthodox schools, and hold all khalīfs save Ali to have been usurpers. They own no khalīfate nor imāmate; these have been dormant since the death of Mohammed, their twelfth imām, in 879, but shall be revived in him when he, the Hidden Imām, reappears as the Mahdi. Shīsm, the ancient protest of Persian patriotism against Arabian ascendancy, has spread through Afghanistan into India, but toward the west has made no way. Toleration and

free thought are common in towns and among the more cultivated Persians, especially toward the north. In 1736 Nâdir Shah tried but failed to restore the Shites to orthodoxy. See KERBELA, NAJAF.

Shikarpur, an important trading town in the north of Sind, stands 18 miles W. of the Indus, on the railway leading to Quetta and Pishin. Before the opening of this railway it was a place of very considerable commercial importance, owing to its situation on one of the principal routes between India and Khorasan—viz. that by the Bolan Pass. It occupies a very low site, the adjacent country being often inundated, but the soil is extremely fertile, and yields heavy crops of grain and fruits. Carpets, coarse cottons, furniture, baskets, &c., are made in the town. Pop. (1921) 55,303.

Shikarry. See SHEKARRY.

Shilka. See AMUR.

Shillelagh, the cudgel carried by the conventional Irishman, with which he is supposed to delight to play upon the heads of his friends on occasion. The name is borrowed from the once famous oak-forest of Shillelagh in the south-west corner of County Wicklow, which in Rufus' day furnished 'cobwebless beams' for the roof of Westminster Hall. The railway station of Shillelagh, 16½ miles SW. of Aughrim, is the terminus of a branch-line.

Shilleto, RICHARD, the greatest Greek scholar of his day in England, was born in 1809, educated at Shrewsbury and Trinity College, Cambridge, and took the second place in the classical tripos in 1832. Shortly after graduating he married, and thus made himself ineligible for an ordinary fellowship. For some five and thirty years his best energies were given to 'coaching' or private tuition, and it was only in 1867 that he was elected Fellow of St Peter's College, and so obtained leisure to realise the great ambition of his life. This was an edition of Thucydides, of which he only lived to publish the first book, dying on 24th September 1876. He edited Demosthenes' *De Falsa Legatione* (1844).

Shillibeer, GEORGE (1797-1866). See OMNIBUSES.

Shilling (O.E. *scylling*), a coin whose name is most probably derived from a root *skil*, 'to divide,' apparently because it was deeply marked with an indented cross, so as to allow of its being easily broken in four. The old Saxon coin of this name was worth about 5d. The shilling in our sense was first coined by Henry VII. in 1504; milled shillings were first coined by Charles II. in 1662. The silver shilling is nominally worth the twentieth part of a pound sterling. But the silver of which shillings are made contains 11 oz. 2 dwt. pure silver to 18 dwt. alloy; and a pound by weight of this compound is coined into 66 shillings; so that each shilling contains 80·727 grains fine silver, and its value as bullion is very much less than its nominal value. The shillings in the old coinages of various north European countries had usually a much smaller value—e.g. the Danish copper *scilling* and the silver *schilling* of Hamburg were each worth less than 1d.

Shilluk, a Nilotic people inhabiting both banks (especially the left) of the White Nile in Egyptian Sudan. They are negroes with a strong Hamitic admixture. See W. Hofmayr, *Die Schilluk* (Mödling-bei-Wien 1925).

Shiloh, a town of the tribe of Ephraim, the first permanent resting-place of the Tabernacle (q.v.), the home of Eli and Samuel, and long the religious centre of Israel. The site is well ascertained—a ruinous village hidden among the hills 20 miles north of Jerusalem.

Shiloh, one of the most desperate battles of the American civil war, takes its name from a log meeting-house, 2 miles from Pittsburgh Landing, which is on the Tennessee River, 8 miles above Savannah. Here, on Sunday 6th April 1862, the Confederates (40,000) under General A. S. Johnston attacked and surprised the Union army (33,000) under General Grant. The battle raged from dawn to sunset, the Federal troops being steadily driven back; but the effort to utterly crush Grant failed, and the next day he won back all the ground he had lost, and the Confederates retreated. On the 6th Johnston was killed while heading the charge of a brigade. The Southerners had 1728 killed, 8012 wounded, and 957 missing; the Northerners, 1754 killed, 8408 wounded, and 2885 missing.

Shimonoseki, a town of Japan (formerly called Akamagasaki), at the south-west extremity of the main island and the western entrance to the Inland Sea, was declared a seaport open to foreign traders in 1890. The batteries and a part of the town itself were destroyed during a bombardment by a combined English, French, Dutch, and American fleet in 1864. In 1895 a treaty of peace was concluded here between China and Japan. Pop. 72,000.

Shin, Loch. See SUTHERLAND.

Shingles (probably derived from Lat. *cingulum*, 'a belt') is the popular name for the variety of *Herpes* (q.v.) which is known as *Herpes zoster*.

Shingles, flat pieces of wood used in roofing like slates or tiles. Such roofs are much used in newly-settled countries where timber is plentiful. The wood is chosen from among the kinds which split readily and straightly, and is usually some kind of fir. It is cut into blocks, the longitudinal faces of which are of the size intended for the shingles, which are then, in Germany, for instance, regularly split off in thicknesses of about a quarter of an inch, but in America are sawn out, somewhat thicker at one end than the other. In the United States shingles, usually some 6 inches wide by 18 long, are in common use, and their manufacture, especially in the Pacific states, has reached enormous proportions. Shaved—i.e. hand-made—shingles of Washington cedar fetch a somewhat better price than the sawn ones. Shingles are laid with one-third of their length (the thick end) to the weather.

Shintôism. See JAPAN.

Shinty, or CAMANACHD, an outdoor winter field game played with ball and stick. It is the national game of the Scottish Highlands, and *camanachd* is the Gaelic name. The field of play is rectangular (not more than 200 yards by 100 yards, nor less than 140 yards by 70 yards), and at each end is set a goal (12 feet wide and 10 feet high) known as a 'hail.' Two teams of twelve a side oppose each other, and the object of play is for one side to drive the ball through the hail of the other. The ball, 7½ inches to 8 inches in circumference, and 2½ ounces to 3½ ounces in weight, is of cork encased in woisted and with an outer covering of leather. The stick (Gaelic *caman*) curves upwards at the striking end, which is triangular in section with the sole as base. Any side of the stick may be used in hitting, play being thus both left-handed and right-handed. There is no restriction as to the height to which the stick may be raised in the course of a stroke. The players are arranged in opposing pairs as in Lacrosse (q.v.) and there is no off-side rule, though, to prevent the gaining of unfair scoring advantage, no player may enter the semicircular area ('10 yards' area) surrounding the enemy hail unless the ball be within that area. Hails may be scored from any

point of the field, either from within or from without the 10 yards' area. Shinty is of the family to which Irish hurlley and Welsh bandy belong, and from that family Hockey (q.v.) derives, but as will be seen with important differences. The game is almost certainly one of the oldest still played in Britain. James IV. practised the sport. Formerly prescribed rules were lacking and games took the form of battles between parishes, sometimes between clans. Inspired by bagpipe music rivals also contended for prizes, as a keg of whisky shared in the end by both sides. After 1887, by the drawing up of rules, order was given to the game, and in 1893 was formed the Camanach Association by which the game has since been controlled and whose cup (first won in 1896) is the great trophy of the year. The present rules of play date from 1896. The game is entirely amateur in character.

Shipbuilding and Shipping. From crossing a river or lake on a floating log or raft, the first steps towards shipbuilding made by prehistoric man, were probably Canoes (q.v.) and Coracles (q.v.). The earliest Egyptian drawings show boats constructed of planks, and having sails as well as numerous oars. From ancient sculptures, the ships of Greeks and Romans appear to have been open, at least in the middle portion; built with keel, ribs, and planking; and strengthened crosswise by numerous benches on which the rowers sat. Ships continued to be of small draught, for they were beached every winter. The Romans built their vessels of pine, cedar, and other light woods; but their ships of war were of oak at the bows, clamped strongly with iron or brass, and having *rostra* or beaks, for use as rams (see *TRIREMES*).]

The hardy Norsemen had tempestuous seas and Atlantic swells to fight with, so their ships differed much from the stately galleys of the empire. A viking war-ship, unearthed in 1880 from a sepulchral mound at Sandefjord in Norway, and now preserved at Oslo, is clinker-built, 78 feet long, 17 wide amidships, and 5½ deep, drawing less than 4 feet of water. She had 32 oars, and one mast, 40 feet high, which probably carried a single square sail. The introduction of galleys by Alfred, pulled by forty and sixty oars, kept the viking war-ships in check; but these galleys were only fit for shore-service. Cnut undertook his final invasion with ships of moderate size, the average complement of each consisting of eighty men. The 'large ships' in which Richard Cœur de Lion in 1190 conveyed his forces to the Crusades were of small dimensions, but depended chiefly on sails for propulsion, not on rowers. The voyage to the Mediterranean was of itself the source of enlarged experience to the sailors, and led to the improvement and increase of British shipping. (The mediæval galley of the Mediterranean is described under Galley, q.v.). Columbus made his first voyage to the New World in the *Santa Maria*, a vessel of 90 feet keel and 29 feet wide, with two small undecked caravels. Henry V. during the early part of the 15th century ordered the construction of several large ships, the wonders of their time. One is recorded to have been about 165 feet extreme length, 112 feet length of keel, and 46 feet beam. Henry VII., and still more Henry VIII., did much to encourage ship-construction, both for war and commerce, the latter building the *Great Harry* (see *NAVY*, Vol. VII. p. 415). The year 1511 saw the construction in Scotland of the *Great Michael*, 'ane varie monstrous great ship,' 240 feet in length, said to have cost about £20,000 Scots.

At this period in the history of shipbuilding the main principles of wood construction were established; and subsequent development in size,

down to the beginning of iron shipbuilding, was mainly characterised by modifications in individual parts or arrangements. Scarcely any advance in the size of ships was made during the reign of Elizabeth, although this was pre-eminently the period of daring navigation. Much, however, was done by her successor to develop both the royal navy and the mercantile marine. He appointed commissions of inquiry into naval affairs; granted a new charter to the East India Company; and endeavoured to raise the standard of knowledge and practice amongst shipbuilders by granting a charter in 1612 to the Shipwrights' Company, and endowing it with jurisdiction over all shipbuilders in the kingdom. The first president of this body was Phineas Pett, master-shipwright of Woolwich Dockyard. To this eminent shipwright, and to his son Peter, and Sir Anthony Deane, naval architecture owed much during the 17th century. But this period of progress was followed by a century of almost utter stagnation in the application of science to shipbuilding. Skill and thoroughness in ship-carpentry as a craft were not wanting; but there was no adequate application of scientific principles to the evolution and improvement of naval architecture. The best scientific talent during this period, and well into the 19th century, was to be found in other countries—France, Spain, Sweden, and Denmark. The British ships produced—particularly ships of war, but also merchant-ships—were, for speed, size, and sea-behaviour, far surpassed by the ships of the countries named. System had become so stereotyped that glaring imperfections—such as the lack of longitudinal and transverse strength—were perpetuated. At length came a shipbuilder who had courage to break away from established practice, and introduce improved methods of construction. Sir Robert Seppings began his career as an apprentice shipwright in the dockyards, and rose to be surveyor of the navy, which position he held till 1832. To counteract longitudinal weakness

he associated with the transverse ribs, or frames, inner ties or riders arranged diagonally (see the section of a wood ship shown by fig. 1). A further modification was the introduction of fillings between the frames up to some distance above the bilges. These fillings, occupying the whole space between the ribs, were of great value as safeguards in the event of damage to the outside planking, and affording additional strength.

A third important change was in the mode of attaching the deck-beams to the frames at the sides of the ship. This bold shipwright also suggested and ultimately effected the reduction of the long

Fig. 1.—Section of a Wooden Vessel.

'beak-heads' and lofty square sterns which had for centuries characterised British war-ships. With Seppings' improvements the way was made clear for increase in the size and power of ships, and the results were exemplified in those three-deckers, long the pride and glory of the navy, and in the staunch and elegant merchantmen known on every sea. The *Thermopylae*, built in

made great reputations and earned for their owners large fortunes about the middle of the 19th century, but steam appliances for managing the sails, anchor, &c., and for dealing with cargo in port, were no inconsiderable part of their equipment. In vessels like *La France* and *Maria Rickmers*, intended for long voyages, the need for such appliances was almost imperative. The incapacity

of sailing-vessels to make progress in a calm is one of their greatest drawbacks, so many of the larger vessels were fitted with auxiliary steam-engines for propulsion. The *Maria Rickmers* had triple-expansion engines of 600 indicated-horse-power, capable of propelling her, fully loaded in calm weather, about 7 knots. They were situated near the stern, and a feathering screw-propeller was used, adjusted by gearing from the engine-room, through

the hollow shafting. The disposition of the blades could be altered, so that they offered the least resistance to the vessel's progress while proceeding under sail alone.

The advent of the internal combustion engine has given the auxiliary sailing-vessel another chance of existence. A new *La France* was built, with oil engines for auxiliary propulsion. In 1921, the largest German auxiliary sailing ship, *Magdalene Vinnen*, was built by Krupp's. She is 329 feet length, 48.2 feet breadth, and has four masts. The gross tonnage is 3476, and the deadweight carrying capacity is 5200 tons. This vessel has four-cycle

Fig. 2.—Four-masted Vessel.

1868, and *Cutty Sark*, in 1869, are among the best known of many famous clipper-ships engaged in the China and Australian trades. (These, however, were composite-built vessels.)

Name.	Gross Tonnage	Length.	Breadth.	Depth.
<i>Thermopylae</i>	991	212 ft.	36 ft.	21 ft.
<i>Cutty Sark</i>	963	212.5 ft.	36 ft.	21 ft.

At the present day wood shipbuilding is mainly a matter of historic interest. It is of very small importance in British shipyards; though at a few ports a little wood shipbuilding is still carried on. Even in Canada and the United States, very little new shipping consists of wood.

Wood has been supplanted by iron, and latterly steel, in the construction of ships, and a corresponding change has taken place in the means for their propulsion. Steamships, and now oil-engined vessels, have made a wonderful transformation, and 'unbought wind' is now seldom used in speeding ships across the ocean. But before this, the size of steel sailing-ships and the extent of their rig had enormously increased. Full-rigged vessels in earlier times had only three masts, but four, and even five masts latterly became not uncommon. Fig. 2 shows a four-masted vessel, with rigging, spars, and sails. The illustration of *La France* (fig. 3), a five-master of 3784 tons, built in 1891, gives evidence of the increased size of hull and the great spread and intricacy of rigging in the colossal vessels of these times. Another and still larger vessel, the *Maria Rickmers*, of 3822 tons, built at Port-Glasgow in 1892, had 56,500 square feet of sail area. Not only were these sailing-vessels much larger than the famous China clippers, which

Fig. 3.—*La France*.

(From a Photograph by Messrs Adamson & Son, Rothsay.)

Diesel engines, of 550 h.p., by Krupp's. The largest British-built auxiliary sailing vessel is the *Kobenhavn*. She was built at Leith for the East Asiatic Co., of Copenhagen, by Ramage & Ferguson, Ltd., in 1921. Her dimensions are 369 feet length, 49.3 feet breadth, and her tonnage is 3901 gross, deadweight carrying capacity being 5300 tons. She has

five masts, and a sail area of 56,000 square feet. The engines are four-cycle Diesel, of 650 b.h.p., by Burmeister and Wain. But even the auxiliary sailing vessel, unless for some particular purpose, cannot compete with the steam or oil-engined vessel, for commercial purposes.

When the steam-engine came into use its suitability for ship propulsion occurred to many minds. The Spaniards claim that Blasco de Gary as early as 1543 attempted to propel a vessel by steam in the harbour of Barcelona. Denis Papin (q.v., 1647-1712) on 27th September 1707 employed a steam-engine to drive a model boat, with paddle-wheels, on the river Fulda, from Cassel to Münden. Jonathan Hulls in England patented in 1736 and described in 1737 a form of paddle-steamer resembling in many essential features vessels still in use. Other inventors proposed more or less feasible schemes for applying to ship-propulsion the crude forms of the steam-engine then known.

The real beginnings of practical steam-navigation, however, are to be found in the period 1780-90; and almost simultaneously, and probably with little knowledge of what was being done elsewhere, the pioneers of progress set to work in Britain, France, and America. The Marquis de Jouffroy (q.v., 1751-1832) produced a paddle-steamboat at Lyons, which, on being tried for speed there on 15th July 1783, attained most encouraging success; but, ruined by the Revolution, he failed to bring his invention into practical use. About 1785 two American inventors—James Rumsey (c. 1743-92) and John Fitch (q.v.; 1743-98)—were independently engaged in steamship experiments. Rumsey in 1786 succeeded in driving a boat at the rate of 4 miles an hour, by jet-propulsion—i.e. steam-pumps forced a jet of water through the stern. Rumsey died in London just prior to trials being made on the Thames with another boat from his plans. Fitch began his experiments with paddle-wheels in 1785; but more successfully in 1787-88 with a series of paddles which had a motion resembling that of the Indian's paddle in canoe-propulsion. In April 1790 another of Fitch's boats made 7 miles an hour, and afterwards plied as a passenger-boat on the Delaware. Fitch disputed with Rumsey and others, the right to be considered the inventor of steam-navigation; but losing all hope of making headway in America, he went to France in 1793. Again in 1796 he was back in America experimenting with a little screw steamboat on a pond in New York. This led to no practical result, and Fitch, disappointed and broken down, retired to Kentucky.

For a number of years experiments with boats driven by paddle-wheels, worked by manual power, had been made by Patrick Miller (1731-1815), a retired Edinburgh banker, on a loch in his estate of Dalswinton, Dumfriesshire. On the suggestion of James Taylor, a tutor to his sons, Miller was led to think of applying steam as the motive-power—though the original idea is also claimed as his. Taylor introduced to him William Symington, a mechanic at Wanlockhead, who had already invented an engine for road locomotion. During the summer and autumn of 1788 the skill and ingenuity of Symington were exercised in constructing an engine after the pattern of his road-engine, for a boat 25 feet long by 7 feet broad, having twin-hulls with paddle-wheels between. On 14th October 1788, this small craft was propelled through the waters of the loch at the rate of 5 miles per hour, in presence of Robert Burns, Lord Brougham (then a boy), Nasmyth the painter, and other friends of Miller. A year later (October 1789) a larger and more powerful vessel was built, and engined for Miller at Carron Ironworks, and tried on the Forth and Clyde Canal, the speed attained

being about 7 miles per hour. Miller, as Carlyle tells us, 'spent his life and his estate in that adventure, and died quasi-bankrupt and broken-hearted.' Symington's pecuniary circumstances did not permit him to experiment further on his own account, and it was not until twelve years later that he had the opportunity of following up previous efforts with one still more successful. Meantime in America others were at work besides Fitch, amongst whom were Samuel Morley, Nathan Read, John Steven, Nicholas Roosevelt, Chancellor Livingston, and Robert Fulton. None of these, however, had materially advanced the cause of ship-propulsion by steam, when in 1801-2 Symington completed for Thomas, Lord Dundas of Kerse, a steam-vessel intended for towing purposes on the Forth and Clyde Canal. This was the *Charlotte Dundas*, the 'first practically successful steamboat ever built.' The engine was of Watt's double-acting type, turning a crank on the shaft of the paddle-wheel, which was situated at the stern. Early in 1802 she was launched on the canal at Grangemouth, and in March that year she towed two laden barges, each of 70 tons burden, a distance of about 20 miles in six hours against a strong headwind. After repeated trials, the proprietors of the canal were urged to adopt the new plan of towing, but, fearing injury to the banks of the canal from the wash caused by the paddles, they declined the proposal. The *Charlotte Dundas* was beached upon the canal bank, and gradually broken up; and Symington, thoroughly disheartened, turned his attention to other matters.

Amongst those who are said, on sufficiently credible authority, to have inspected the *Charlotte Dundas* were Robert Fulton (q.v., 1765-1815) and Henry Bell (q.v., 1767-1830), two enterprising spirits, afterwards destined—one in America, the other in Scotland—to achieve permanent success with steamships. Fulton went to Paris in 1797, and for some years was engaged experimenting with submarine torpedoes and torpedo boats. About 1801-2, jointly with Chancellor Livingston, then ambassador at the court of France, he built a steamboat on the Seine, the engine for which, proving too heavy for the hull, caused it to collapse and sink. Nothing daunted, Fulton recovered the machinery and placed it in a new and stronger boat, 66 feet long by 8 feet broad. On 9th August 1803 this boat was tried on the Seine, but attained only very limited speed. Fulton, returning to England in May 1804, remained for over two years; and there he ordered and saw completed by Boulton and Watt, a steam-engine which Livingston and he intended should be utilised in America. He sailed in October 1806, the engine following, and in August 1807 it was part and parcel of the *Clermont*, a vessel 133 feet long, 18 feet broad, and 9 feet deep, built to Fulton's order. Her first trip between New York and Albany, a distance of 142 miles, was made in thirty-two hours' steaming time, and the return journey occupied thirty hours. The *Clermont* was undoubtedly the first steamboat profitably employed—at least continuously—in useful service, and Fulton is accordingly entitled to the distinction of having been 'the first to make steam-navigation an everyday commercial success.'

America, with its enterprise and its great natural field for inland-navigation, was infinitely better prepared for the innovation than the old country, with its traditional achievements, conservatism, and prejudices. Yet Henry Bell's venture in 1811-12 is worthy of admiration. Henry Bell, by training a millwright, was proprietor of a hotel at Helensburgh on the Clyde. He long had convictions of the high place which the steam-engine would take

in ocean-navigation, and had knocked at the door of both the British and American governments for encouragement to prosecute his ideas. The ultimate result of his own financially unaided efforts was the renowned *Comet*, which was launched from the yard of John Wood, Port-Glasgow, in January 1812. She was 42 feet long, 11 feet broad, 5½ feet draught of water, and her engine was of 3 horsepower. She plied on the Clyde from Glasgow to Helensburgh, and thence across the river to Greenock, her speed being about 5 miles per hour. After her immediate successor, the *Elisabeth*, and other steamers had been built and were running successfully, the *Comet* was lengthened to 60 feet, and fitted with a new engine and a single pair of paddles (at first there were two paddles a side), and attained a speed of 6 miles an hour.

The building of steamships was soon fairly established, and the Clyde took the lead in their construction. While most of them were intended for home, river, or coasting trade, not a few were built for service at distant ports. Of four passenger-steamers produced in 1814, *Marjory* was the first to ply upon the Thames, having been bought by a company of London merchants soon after her launch from the yard of William Denny of Dumbarton. She passed through the Forth and Clyde Canal from Bowling to Grangemouth, and reached the Thames six days after leaving the Forth. A notable trading steamer, *Industry*, was built by Fife the same year. Engineering received a forward impetus from the energetic genius of David Napier, already a well-known marine engineer, of Glasgow. He grasped the possibilities of steam-navigation in connection with coasting and over-sea traffic. In 1818 he established regular steam-service between Glasgow and Belfast with the *Rob Roy*, built by William Denny, and fitted with engines of his own make. She was the first regular sea-going steamship in the world, and, largely owing to the success of the *Rob Roy*, steamers were built and employed in service at other ports. In 1819 he established the first line of steamers between Glasgow and Liverpool, and during the subsequent twenty years he engined the most notable steamers produced by Clyde builders. On the Thames steamers began to ply between London and Margate in 1815-16; and in 1817 James Watt, whose double-acting side-lever type of engine (see STEAM-ENGINE) had played such an essential part in the movement, crossed over to the Scheldt in a steamer named the *Caledonia*, afterwards ascending the Rhine to Coblenz.

Ocean voyages by steamers were at first performed by vessels in which sail almost as much as steam was the power relied on. In this way the Atlantic was first crossed in 1819, by the *Savannah*, a vessel 100 feet long and of about 300 tons burden, the passage from Savannah to Liverpool occupying twenty-five days. In 1824 the steam-yacht *Falcon*, of about 175 tons, proceeded from England to India, for the most part relying on sails. In 1825 the *Enterprise*, 122 feet length of keel by 27 feet beam, and of about 470 tons burden, made a passage from London to Calcutta in 113 days, ten of which were occupied by stoppages.

The successful inauguration of transatlantic steaming is due to the *Great Western*, built for the Great Western Steamship Company by I. K. Brunel, whose bold genius controlled the affairs of the company, and gave to the maritime world several of its most notable steamships. She was 212 feet long, and registered 1340 tons. Her engines, on the side-lever principle, made by Messrs Maudslay, Sons, and Field, of London, were of 440 horsepower. On Sunday, 8th April 1838, the *Great Western* left Bristol on her voyage across the Atlantic, her completion and despatch being

hastened on account of the fact that, four days earlier, a vessel named the *Sirius* (taken from the service between London and Cork) had started on the same voyage. The *Sirius* was smaller and less powerful than the *Great Western*, and both vessels arrived at New York on the same day, Monday, 23rd April—the *Sirius* in the morning and the *Great Western* in the afternoon—the passage thus taking eighteen days and fourteen days respectively. Their arrival was hailed with immense acclamation by a vast concourse of spectators. The event was a triumph in steam-navigation, regarding the possibility of which much popular unbelief and some scientific doubt had been expressed; and it virtually reduced the distance between the Old World and the New by about one-half. The return passages of the *Great Western* and *Sirius* were even more successful than their outward, for time occupied and fuel consumed, but the undertaking commercially was far from satisfactory. Other steamers followed, but, with the exception of the *Great Western*, which was kept running at a loss, they were gradually withdrawn from the service.

A historical survey of the transatlantic service affords in itself a more complete and connected epitome of steamship development in all its essential aspects than any other service that can be instanced. The profiles of typical Atlantic steamers from the *Sirius* onwards for sixty years are reproduced here through the courtesy of the proprietors of *Engineering*. In 1839 Mr Samuel Cunard (q.v.) came over to England from Halifax, determined to establish on a secure and satisfactory basis a line of transatlantic steamships. He was brought into contact with Mr George Burns of Glasgow and Mr David M'Iver of Liverpool. The necessary capital was soon raised, and the celebrated 'Cunard' Company, backed by a handsome government subsidy for prospective mail services, was the result. Their first vessels were the paddle-steamers *Britannia*, *Acadia*, *Columbia*, and *Caledonia*, all of about the same dimensions—viz. 207 feet long, 1154 tons burden, and 740 h.p. The engines were of the side-lever type, by Robert Napier of Glasgow, return-flue boilers and jet-condensers being used. The *Britannia* inaugurated the mail service by sailing from Liverpool on Friday 4th July 1840, and arriving safely at Halifax after a voyage of twelve days ten hours. Her return passage was made in ten days; and the mail service thus instituted was thenceforth carried on by these four vessels with great regularity. The average speed then attained was about 8½ knots, and by 1848, when longer and more powerful vessels were running, the average speed had been increased to 10½ knots.

The substitution of iron for wood in the construction of ships' hulls commenced with barges and light craft built for canal and inland service. Amongst the first builders of iron boats were John Wilkinson, an iron-founder at Cartmel in North Lancashire, in 1787 or earlier; Thomas Wilson, on the Monkland Canal, Scotland, in 1818; and John Laird, founder of the Birkenhead firm, in 1829. The first iron steamer was the *Aaron Manby*, built at Horsely Ironworks, Tipton, in 1820-21, and named after her designer and builder. The first iron steamer constructed on the Clyde was the *Aglaia*, in 1832; the first on the Tyne, the *Prince Albert*, was built the same year. The distrust and opposition which this great change met with, not only from the public, but from shipowners, builders, and naval authorities, hindered its development for many years. The building of the *Great Britain* for the Atlantic service during the years 1838-44 was, therefore, a characteristically bold step on the part of Brunel and the company

for whom he acted. This remarkable vessel, the marvel of her day, was a striking exemplification not only of the natural evolution of steamship dimensions, but of the revolution in construction and propulsion. She was over 274 feet in length. Her hull was constructed of iron, and she was fitted with a screw-propeller. The employment of the screw in place of paddles was resolved upon in 1839 (the engines designed for paddle-wheels had been partially made) after painstaking study of the screw as already applied to smaller vessels.

The idea of employing the principle of the screw for ship-propulsion is known to have been entertained from a period as early as the application of steam power. But the subject is so beset with many intricate and conflicting contentions that it would be futile to attempt a satisfactory statement here.

Amongst the first, however, to convince the engineering profession of the practicability of screw-propulsion, were John Ericsson (q.v., 1803-89) and Sir Francis Pettit Smith (1808-74). The former with the *Francis B. Ogden* on the Thames in 1836 obtained encouraging success, and the latter with the *Archimedes*, a vessel of much larger size, in 1839, clearly demonstrated the practicability and value of screw-propulsion. The innovation in the case of the *Great Britain* was a success. But the great misfortune which overtook her on her fourth voyage from Liverpool to New York, stranding in Dundrum Bay, Ireland, through a misreckoning, interrupted her successful career as a steamship, although she was long afterwards employed in the Australian service. This misfortune, however, helped incalculably to further shipbuilding in iron.

Fig. 4.—Comparative Sizes of Typical Atlantic Liners.

(From *Engineering*, 4th December 1891. The *Oceanic*, from drawing kindly furnished by Messrs Harland & Wolff)

The vessel, after lying aground in an awkward situation for about eleven months, was successfully floated, and found to have sustained comparatively little damage. Many shipbuilders and owners who had hesitated about employing iron, paid visits to the stranded vessel, inspected her after docking, and felt entirely convinced of the suitability of iron for ship-construction. Although for some time longer the transatlantic service continued to be conducted by wooden vessels propelled by paddle-wheels, ocean-navigation by iron steamers was now placed on a thoroughly practical basis, and the superior efficiency of the screw for overseas propulsion became accepted.

The advantages of the screw-propeller for ocean-steaming as compared with the cumbersome paddle-wheel were many. In smooth water, its efficiency was then not much greater than the paddle-wheel, but its position relatively to the body propelled, and to the water through which that body passes, made it vastly more efficient for sea-going purposes. Placed at the stern of the vessel, and fully immersed, it acts upon relatively undisturbed water. The rolling motions which so adversely affect the paddle, leave the screw almost uninfluenced and free from liability to damage. If the screw be well immersed, even the rising of the stern and dipping of the stem do not entail any

great loss of efficiency. Again, considerable variations in a ship's draught of water may take place and leave the screw efficient; whereas in the case of the paddle a small decrease or increase in the 'dip' of the floats, whether caused by draught of water or by wave-hollows, makes a very material difference.

The virtual monopoly of the Atlantic steamship service which existed for ten years in the hands of the Cunard Company was seriously assailed by opposition in 1850. There was established in that year the celebrated 'Collins' Line of paddle steamships, four in number, American built, of superior power and speed, and backed by a substantial subsidy from the United States government. The ultimate issues were greatly in favour of the Cunard Line, the Collins opposition ceasing in 1858 after the loss of two of the vessels and the refusal of further financial aid by the American government. With iron ships propelled by screws the Inman Company entered on Atlantic competition about the same time. Their first vessel was the *City of Glasgow*, followed by the *City of Manchester*, both built by Tod and M'Gregor on the Clyde. The Cunard Company in 1852 sent forth the *Arabia*, a wooden paddle-steamer of 2480 tons and 938 h.p. This was followed in 1855 by the *Persia*, the first iron vessel the company owned,

with which they maintained first place for speed. The next addition to the fleet—referred to at the time as the 'champion and model of a mercantile ocean steamship'—was the *Scotia*, built of iron, but she also had paddle-wheels. She measured 379 feet long, her gross tonnage being 4676. Her engines, by Napier, indicated at sea as much as 4200 h.p. Although her early performances surpassed those of any previous vessel, she was the last of the paddle-steamers built for the Atlantic by the Cunard Company. In the same year which gave her birth the government sanctioned the use of the screw-propeller in the mail steamers of the company, and the screw-steamer *China* was the result. This vessel was followed during the next two years by four others, whose performances finally established the fact that the screw-steamer in point of efficiency and economy, especially with the improvements which had concurrently taken place in the marine-engine, far surpassed the paddle-steamer for deep-sea traffic.

With the triumph of iron construction and screw-propulsion development in size and power proceeded swiftly. Steam-navigation grew and flourished amazingly, and the employment of steamers on the longest of voyages and at high rates of speed was now thoroughly established. Additional companies were formed, and new steamships produced, for services having the widest ramifications.

The first mercantile steamship company to develop the trade of Britain with India by way of the Isthmus of Suez was the Peninsular Company, afterwards the renowned Peninsular and Oriental Company, their first services dating from 1837. The Pacific Steam-Navigation Company was established in 1847, and it was in vessels built for this company in 1856, engined by John Elder, that the compound principle, destined to prepare the way for the marvellous improvement gradually effected in the marine steam-engine, received its first satisfactory credentials. The subsequent general adoption of the surface-condenser and the cylindrical multitubular boiler enabled higher pressures of steam to be safely and economically produced and used.

The year 1858 witnessed the completion of the *Great Eastern* (q.v.)—Brunel, and Scott Russell's, stupendous creation—and also saw the modest beginning of the great fleet of the North German Lloyd. In 1861 the French Compagnie Transatlantique was inaugurated. About 1877 the Orient Steam-Navigation Company instituted a fortnightly service to Australia, and in 1879 added the *Orient*, and in 1882 the *Austral*, to their fleet, both from the stocks of the Fairfield Company, Glasgow. The *Orient* on trial attained 17 knots, and afterwards made the passage from Plymouth to Adelaide *via* the Suez Canal in 35 days 16 hours; and the same voyage *via* the Cape in 34 days 1 hour, steaming time. In a steamer built for the Australian service in 1881 by Napier & Sons—the *Aberdeen*, for G. Thomson & Co.—the merits of the triple-expansion engine were first decisively shown. The machinery of this vessel was from the designs of A. C. Kirk, of Napier's. The boiler pressure was 125 lb. per square inch, and expansions took place in three cylinders. On her first voyage from Plymouth to Melbourne, which occupied 42 days, her average i.h.p. was about 1800 and consumption of fuel less than 34 tons per day, a rate of 1.69 lb. per i.h.p. per hour. In 1883 the New Zealand Shipping Company instituted direct steamship service to New Zealand. In vessels employed in this service, a further extension of the principle of higher pressures and increased expansion—quadruple—was carried out with corresponding economic results.

A hotly sustained contest for the leading place

in the race across the Atlantic began in the year 1874 with the production of the *Britannic* and *Germanic*, of the White Star fleet, by Harland and Wolff, Belfast—each a considerable advance on anything then existing. Steamship after steamship proved more or less an advance on its predecessor in length, appointment, propulsive power, and consequent shortening of the passage time. Each increase in the high-speed Atlantic steamer represented the resultant of innumerable modifications—some minor, others radical—which engineering experience and skill and the constant improvement in contributory branches of art and manufacture suggested and rendered possible. For a time the White Star line maintained first place in the matter of speed, being exceeded, however, in dimensions and tonnage by the *City of Berlin* of the Inman Line, in 1875 the longest vessel afloat next to the *Great Eastern*. The average time from Sandyhook to Queenstown in 1856 was 11 days 19 hours. Roundly stated, the *Britannic* reduced the passage to and from Queenstown and New York to 8½ days. In 1879 two fresh competitors were in the field, the *Arizona* of the Guion Line, built by the Fairfield Company, and the *Gallia* of the Cunard Company, built by J. and G. Thomson, Clydebank. During 1881 the Cunard Company added the *Servia* to their fleet, from the stocks of J. and G. Thomson; the Inman Company added the *City of Rome*, from the Barrow Company; and the Guion Company the *Alaska*, from the Fairfield yard. Then came the *Oregon* (Fairfield), for the Guion Line, in 1883; the *Aurania* (Clydebank), for the Cunard Company, in the same year; the *America* (Clydebank), for the National Line, in 1884. The *Umbra* and *Eturia* (Fairfield) were the last single-screw vessels built for the Cunard Company.

Twin-screws were soon found particularly suitable in steamers for coasting and cross-channel work, where depth of water is restricted, and in vessels of the navy, where manœuvring facility is a desideratum. In vessels of large power it was also recognised as inadvisable to transmit the total power through one line of shafting. Mishaps to the shafting or propellers of single screw steamers were too frequent. With twin-screws, each driven by a separate set of engines and shafting, ships can, in the event of a break-down to one set of machinery, still pursue their voyage by means of the other set. The twin-screws can also be used to assist the steering in case of emergency.

The *City of New York*, *City of Paris*, *Majestic*, and *Teutonic* (1889) were the first twin-screw Atlantic liners. Of the same class were the *Normannia*, *Auguste Victoria*, *Furst Bismarck*, and *La Touraine*, belonging to German and French firms. At Fairfield (1893) were built the twin-screw *Campania*, and *Lucania*, for the Cunard Company. In 1899 Harland & Wolff launched the *Oceanic*; and in 1902 the *Cedric*, both for the White Star Line and with twin-screws.

In later steamships of the largest dimensions and highest powers, triple and quadruple screw-propellers have become necessary. In 1900 the Hamburg-American twin-screw liner *Deutschland's* time was 5 days 7½ hours—an average speed of 23.38 knots. The Cunarders *Lusitania* and *Mauretania*, quadruple-screw turbine steamers launched in 1906, inaugurated a new departure. Both vessels on their trial runs of 1200 miles attained a mean speed of over 26 knots. The *Lusitania* on 10th July 1908 completed the passage from Queenstown to New York in 4 days 19 hours and 36 minutes, the average speed being 25.01 knots. But the *Mauretania* holds the blue ribbon of the Atlantic, having on 6th October 1924 completed the voyage from New York to Plymouth in

4 days, 21 hours, 51 minutes, an average speed of 25.68 knots, although the crossing was rough.

These huge vessels have been followed by even larger ones, such as the *Olympic*, built in 1911; *Berengaria* (German *Imperator*), built in 1912;

Fig. 5.—Comparative Sizes of Typical Steamships.

Aquitania, built in 1914; *Leviathan* (German *Vaterland*), built in 1914; *Majestic* (German *Bismarck*), built in 1921; and others not quite so large. The ill-fated *Titanic*, built in 1912, was 46,329 tons. A table giving a few particulars of representative vessels is appended.

The introduction of the steam-turbine was a great step forward in marine propulsion (see STEAM-TURBINE). In 1901-2 the passenger turbine steamers *King Edward* and *Queen Alexandra* were run on the Clyde, with an average speed of 20 knots. The Allan liners *Victorian* and *Virginian*, and the Cunard Company's *Carmania* (1905), followed, and the turbine soon became established for high powers. The Admiralty, after experiments on the cruiser *Amethyst*, adopted it for the *Dreadnought* (1906). (See NAVY.)

The latest development in steam propulsion is a very high pressure watertube boiler, in conjunction with Parson's geared turbines. A vessel with this type of machinery, *King George V.*, was built by Denny in 1926.

In recent years oil fuel has been largely used for marine steam boilers. By adopting oil fuel in place of coal, a number of steamships have attained an appreciable increase in speed.

The internal combustion engine has brought about an enormous change in ship propulsion within the last few years, and the Diesel engine is now acknowledged to be the most suitable for certain classes of vessels. Not only in cargo vessels but in passenger vessels this type of engine is being adopted. The first large motor vessel of the 'liner' type is the *Aorangi*, built in 1924 at Fairfield for the Union Steamship Co. of New Zealand. There are four propellers, and the machinery consists of four sets of 'Sulzer' two-stroke single-acting engines, each having six cylinders, giving a total of 13,000 h.p., and a sea speed of 17 knots. A speed of 18.23 knots was attained on the measured mile trial. She is running successfully on the Pacific. The *Gripsholm*, 17,300 gross tonnage, built by Armstrong in 1925, developed on her first voyage across the Atlantic a maximum speed of 16.95 knots for 24 hours. She has two propellers driven by Burmeister and Wain engines of the double-acting, four-stroke type, each having six cylinders. In the same year Harland and Wolff launched two passenger liners, *Asturias* and *Alcantara*, for the Royal Mail Steam Packet Company. These vessels are 22,000 gross tonnage. They have twin screws, and engines of the Burmeister and Wain double-acting type, each having eight cylinders. At the Ansaldo Yard in Italy the largest motor vessel in the world—*Augustus*, 32,000 gross tonnage—was launched in 1926. She will have four engines of the M.A.N. double-acting type, each having six cylinders, developing in all 25,000 h.p., and a speed of 21½ knots is anticipated. Geared Diesel engines for marine propulsion have been used with success in Germany.

The employment of electrical energy for propulsive power has already met with considerable success, and it may be assumed that electricity will play a great part in propelling the 'ship of the future.' The greatest progress in the steam Turbo-electric system has taken place in America, and a passenger vessel of 22,000 gross tonnage is building for the International Mercantile Marine of America; 18,000 shaft horsepower is to be developed, and a speed of 18 knots expected.

Mild steel was first used as a building material in France, but soon attracted the attention of British naval authorities; and about 1875-76 home manufacturers supplied the steel requisite for the construction of the cruisers *Iris* and *Mercury*. In 1879 the Allan Line entrusted to William Denny and Bros. the building of the *Buenos Ayrean* (the largest vessel of their fleet up to that time), the hull of which was of steel with steel rivets. Almost from the first, mild steel found favour with the shipyard workers, being a material capable of much easier manipulation than iron; but its high cost and the exacting tests necessarily imposed restricted its use for some years. Improvements in manufacture and enlarged facilities for production gradually reduced its cost and established its reliability. Steel has many advantages. It is light—strength for strength—compared with iron. There is economy in labour through steel lending itself more than iron to being worked while in the cold state. It may be readily and safely flanged and joggled, thus dispensing with many bars, butt straps, &c., and it can be supplied in plates of greatly increased size. The change from wood to iron effected a saving of 30 to 40 per cent. in the weight of a ship's hull. The employment of steel made a further economy in weight of almost 15 per cent. Roughly, therefore, the steel ship of to-day is 50 per cent. lighter

than a wooden ship of former times of similar dimensions and tonnage. Finally, the greater safety of steel ships, and the diminished risk of heavy damage requiring repair, in the event of getting aground, commended steel to shipowners and marine insurance societies. Through the superior ductility of the material, steel ships have again and again come comparatively scathless out of ordeals which would have proved serious to ships built of iron.

A high tensile steel has been successfully used for many years, especially in naval vessels.

Recently a special quality steel, having a higher limit of elasticity than ordinary mild steel, has been introduced, and is approved by Lloyd's Register of Shipping.

Fouling and corrosion in service is a disadvantage attaching to steel as well as iron ships. The marine growth, which takes place more or less rapidly on iron and steel ships, especially in warm or tropical seas, has been a serious matter for the navigator and the shipowner. A few months in tropical waters may produce such an amount of fouling that the speed of the ship is considerably

reduced. Copper-sheathing formed from a very early date an essential item in the proper fitment of a wooden vessel for sea. Its anti-fouling properties were so advantageous that long after iron had supplanted wood generally, the 'composite' system of construction was in many cases followed. A ship built on this system resembles an iron ship, except that wood is used for the keel, stem, sternpost, and planking, thus enabling the bottom to be sheathed with copper. For a considerable period the composite system of construction found favour in ships of war and mercantile ships intended to keep the sea for long periods and to maintain their speed. The China clippers formerly employed in the tea trade, whose annual races home excited so much interest, were built on this system. There have been innumerable attempts to prevent the fouling of iron and steel ships, but in spite of countless specifics proposed, frequent docking and

careful coating of the hull with paints and anti-fouling compositions are the best methods

The employment of iron in place of wood for constructional purposes, and the simultaneous extension of the use of machinery, revolutionised the art of shipbuilding. The manipulation of this malleable material and of its still more ductile successor, mild steel, is simplicity itself compared with the elaborate hewing and fashioning of timber requisite in wood shipbuilding. Take, for example, one of the important parts of a ship's structure, the rib or frame. In a wooden vessel it was a matter of careful and skilful workmanship to saw and hew from rough logs the curved timbers, many of which had to be combined to form a single rib. In a steel ship, angles or other sections used for frames are simply heated in a furnace and then bent to the required curve. Each frame in its complete form consists

of the simplest possible combination of angles or other bars and plates. Further, the manufacturer supplies the material approximately of the dimensions in which it enters into the structure, thus reducing the work of cutting and preparation to a minimum. Machinery, too, has assisted handicraft in the shipbuilding yard. Plates and bars are

tradesmen aiding in the fittings and equipments; whereas in steel shipbuilding there is no correspondingly prominent artificer of the 'all-round' type, the work being apportioned among machine-aided ironworkers, carpenters, and joiners. Shipbuilding may, in these respects, be said to have lost dignity as an art. But there is a great

gain to steel shipbuilding as an industry, and the modern vessel as a product of science. The rate of production is accelerated tenfold compared with what it was even in the palmiest days of wood shipbuilding; and in size and perfection of equipment the mail-steamers and ironclads produced from the yards of our shipbuilding centres dwarf the achievements of former times.

Sub-division of the hull of a vessel by strong water-tight Bulkheads (q.v.) is essential, to guard against foundering through collision or grounding. Should the shell be penetrated and an inrush of water take place, the inflow is confined to the space between two bulkheads, and there is enough buoyancy in the remaining compartments to keep the vessel afloat. Many ships are now compelled to be so subdivided that if any two compartments be laid open to the sea the vessel would not sink. In most vessels commercial and other conditions restrict the degree and nature of subdivision to only such as the law demands. The principle of subdivision has been extended in another part of the hull structure, viz. throughout the bottom. The carrying of water-ballast has for very many years been rendered necessary for vessels compelled by exigencies of service to proceed to sea light, or partially loaded; and this need, associating itself with structural requirements arising from the growth in ship's dimensions, has resulted in the general adoption of double bottoms, on the 'cellular' principle. This internal feature of a ship's structure dates from before the time of the *Great Eastern*, in which, as well as in previous smaller ships built by Scott Russell, the cellular system was adopted, although not associated with water-ballast. It contributes to the security of a vessel grounding or striking sunken obstacles, because the top of the cellular bottom or 'inner shell' is water-tight. Through the courtesy of William Denny and Bros., Dumbarton, who did much to improve the cellular system, a midship section is reproduced of an early example, the steamship *Scot*. The longitudinal strength obtained by the girders and inner plating is combined with the transverse 'deep-floor' principle, and the whole util-

punched, sheared, drilled, planed, and bent by simple and suitable machines. One or two skilled workmen, assisted by several unskilled labourers, can rapidly perform operations corresponding to those which in wood necessitated the handicraft skill and prolonged efforts of many trained shipwrights. Division of labour also enters into the economy of modern shipbuilding to a much greater extent than in wood shipbuilding. The shipwright, as his name implies, really built the wood ship, other

used for carrying water-ballast.

The project for a new vessel originates generally with the shipowner, and from his experience he submits to the professional marine architect the main regulating conditions of design—e.g. the proposed dimensions, the type, the cargo to be carried, and the speed to be attained on a given draught of water. From these and other fundamental data the architect is able to prepare a suitable design and a detailed specification,

which the owner can lay before one or more builders and obtain prices for constructing the vessel. After the contractor has been selected there remains a goodly amount of designing to be done in details, and the preparation of working-drawings to guide the workmen in the shipyard.

The building of a modern vessel is usually undertaken by one firm of shipbuilders who are also marine engineers. The first step is the preparation of plans, showing by a series of curved and straight lines the form of the ship's hull, on three distinct planes: (1) the 'sheer-plan' or longitudinal elevation, showing the lines of length and height; (2) the 'half-breadth plan,' showing the lines of length and breadth; (3) the 'body-plan,' showing lines of breadth and height.

Following the design of the form is the preparation of a 'midship section' showing the transverse shape of the vessel amidships and the

helps the owner in all subsequent negotiations connected with insuring the vessel and her cargo. Elaborate classification rules and scantlings have been formulated and are issued annually by Lloyd's Register and other societies.

From the design a wood half-model, which is a small-scale representation of the hull, is prepared for various constructional purposes. On its surface are marked vertical lines from keel to upper deck representing the frames. These are spaced at equal distances apart from the stern-post to the stem. Across these, in a longitudinal direction from stern to stem, lines are drawn representing the edges of the shell-plating, arranged in 'strakes,' each strake being divided throughout by 'butts' into uniform lengths of plates. Lines representing the decks, transverse bulkheads, side-ports, and other details are also drawn thereon. From the model thus prepared, and from plans, of decks, bulkheads, keelsons, and floors, the draughtsman measures and orders the bars, plates, and butt straps. Meanwhile the vessel's lines have been 'laid off' on the mould-loft floor full size, in which process inaccuracies due to the small-scale drawing are eliminated. When the mould-loft lines are accurately 'faired,' moulds and templates of several parts of the ship's structure are prepared for the workmen in the shipyard. The most important item thus prepared is the 'scribe-board,' a stout wood flooring on which the frame curves and other details are drawn full size by sharp lines cut or 'srieved' in the smooth surface. This board is then placed convenient to the furnace and the 'bending-blocks,' massive cast-iron slabs on which the frames are bent. On these blocks the form of a frame is marked from the scribe-boards. All over the blocks are round holes, closely spaced, and into those which fall within the line of the frame curvature pins are placed with their upper ends projecting. A bar properly heated is drawn from the furnace and speedily bent by special hand appliances, and held by the pins and dogs to the form required, and it is also bevelled. Each half-frame of a ship is thus fashioned to the proper curve in little more time than it takes to describe the process.

Fig. 8.—Section of Bars.

It is allowed to cool and then taken to the scribe-board to be finally adjusted. This along with a 'reverse frame' and a 'floor' plate makes one of the ship's ribs or frames in its complete form. These three items first bolted together are then riveted together by hand or hydraulic power, the holes for the rivets having been punched by machine, partly before and partly after bending. Beams and other parts are similarly furnace and shaped. The keel has in the meantime been prepared and laid on heavy blocks of wood or moulded concrete—about 4 to 6 feet apart and 3 to 4 feet high—their tops lying in a plane inclined to the horizon about $\frac{1}{8}$ inch per foot. The completed frames are hoisted up in their places and kept in position by shores and ribbons. The stem and stern-post are also set up, and soon the work becomes general all over the vessel. The deck-beams are put up, the bulkheads, stringer-plates, and keelsons are added in due succession, and the outside shell-plates are curved, fitted, punched, temporarily fastened with bolts, and then riveted.

In vessels built on the cellular double-bottom

Fig. 7.—*Aquatania* Midship Section.
(From the Trans. of the Inst. of Nav. Archit.)

sizes, or scantlings, of the various parts which constitute the structure (see specimen midship sections, figs. 6 and 7). If the vessel is to be 'classed'—as the majority of vessels at the present day are—this 'midship section' is submitted to Lloyd's Register of Shipping or other registration society for approval. The practice of classing at Lloyd's (q.v.) is advantageous in several ways, and it

principle the order of procedure is somewhat different from the foregoing in the earlier stages. The frames are usually in three parts. One part forms the bottom of the vessel, each side of a centre longitudinal, to which it is securely attached, and ends against a wing-plate at each bilge. The two remaining parts form the sides, and are superimposed upon the wing-plates and firmly bracketed to them. In construction, therefore, a centre longitudinal plate fixed vertically, and a flat keel plate are first erected; the bottom sections of the frame are then fixed in place, and the whole system of longitudinal and deep-floor plates completed before the side portions of the frames are erected. In other respects the procedure does not materially differ from that above outlined. These methods are called transverse framing, and there are many modern modifications.

There are other methods of 'framing.' Vessels are frequently built on a longitudinal system, the *Great Eastern* being the earliest outstanding example of the kind.

The steel work entering into the structure is fastened together by rivets. Holes are punched or drilled in the plates and bars in most cases before they are put together. The holes having been made exactly to fit over each other, and the plates held closely together, a red-hot rivet is inserted

Fig. 9.

through them, as in *b*. A workman holds the head of the rivet forcibly in place with a heavy iron tool, while two riveters on the other side of the plate strike its point rapidly with their hammers until hammered down almost flush with the plating. It is then finished off as shown at *a*. The contraction of the rivet in cooling causes it to

draw and hold the two plates still more tightly together. In modern practice much of the riveting is done with hydraulic and pneumatic tools.

The outside shell of the vessel, also the bulkheads and other necessary parts, are made watertight by 'caulking'—i.e. forcing the edge of one thickness of plating against the surface of the other by blows from a hammer on a chisel-like tool. With the completion of the riveting and caulking of the shell, the laying of decks, and the concurrent advance of other features, the vessel is prepared for launching. Launching 'ways' of heavy timber are laid down parallel to the keel at some distance on each side of it, under the bilges of the vessel, and extending into the water below high-water mark. A 'cradle' is then built under the ship, the bottom of which is formed of smooth timbers, or 'sliding ways,' resting upon the fixed launching ways. Before launching, the rubbing faces of both of the ways are well greased, and gradually, by wedging, the weight of the ship is transferred from the building 'keel-blocks' and bilge-blocks to the cradle and ways. By a locking arrangement of the two ways the tendency of the ship and cradle to glide down the lubricated pathway is prevented until the proper moment. When this arrives (at high-water usually) the ceremony of naming the vessel takes place, the locking arrangement or 'dog-shore' is released, and the vessel glides down the ways with gradually increasing velocity until checked by the resistance of the water, or by chains and drag-weights on shore. As soon as the vessel is 'water-borne' the cradle floats apart in pieces, which are afterwards towed back to the shipyard. The engines and boilers have of course been under construction since the date of the order, and their erection and fitting devolve on the engineering department.

Although the vessel is now afloat much may

remain to be done. Frequently a considerable part of the deck-planking has to be laid and caulked after the machinery has been put on board, and the cabin appointments and other interior and deck fittings have to be completed; the masts have to be put on board and rigging fitted. The engines, boilers, shafting, and the various items of auxiliary and deck machinery have to be placed and properly secured on the seatings provided for them. All is at last complete: the numerous deck-fittings, the furnishing of the rooms, the fitting of electric light, the heating and refrigerating plants, the cooking appliances, the sanitary fittings and ventilation, the completion of the network of piping, the fitting of the steering gear, the placing of the compasses, the life-saving appliances, and the thousand-and-one other items which go towards the thorough equipment of the vessel for sea. When the vessel glides out of the dock of her builders and proceeds on her trial trip, and to adjust compasses, there ensues what is not infrequently a most anxious period for the builders and engineers. In vessels where high speed, together perhaps with carrying capability on a given draught of water, is the regulating condition of design, the speed trials are often most exacting. The 'measured mile'—i.e. the nautical mile of 6080 feet determined by fixed marks on a straight length of coast-line—is usually the means by which a vessel's speed is ascertained; but in addition to running the mile most high-class vessels have to undergo continuous tests over long distances. Two or more runs are made over the mile, with and against the tide, the object being to eliminate the tide's influence from the results. The time taken to each run enables the builder to compute the rate of speed per hour of which the vessel is capable.

Speed, power, and dimensions must not be gained at the expense of stability, strength, and safety, and these qualities are duly balanced in the magnificent ships traversing the Atlantic and other oceans. In the paddle and screw vessels employed in other kinds of service—such as river, lake, and cross-channel passenger work—practical skill and scientific knowledge are equally exemplified. In the purely cargo and freight-carrying vessels, while fundamentally the same conditions obtain, there are other influences and restrictions, due to the exigencies of commerce and of economic service, which affect the balance of qualities. Speed may be subordinated to economic consumption of fuel; stability may be regulated less by the ship's form and weight-distribution in the hull structure than by the amount and distribution of cargo when the ship is fully loaded. The present-day designer is concerned not so much with attaining great success in any one direction, as with fulfilling various and conflicting conditions of service at moderate outlay.

The attention of the shipping world has frequently been called to novelties in ship design and construction, but commercial and industrial caution have hitherto kept their balance, and the ultimate effect has been to illumine and make clear the safest line of advancement. That ships of certain types will continue to increase in size and speed may be taken for granted. But the future dimensions of ships depend largely on the provision of deeper entrances to the principal harbours in the world, and larger dry docks and port facilities.

With the development of propulsion by engines instead of sails, the shipbuilding industry not only flourished in the United Kingdom, but became general in countries which are favoured as repositories of natural wealth in the form of coal and ores. The other leading countries are the United

States, Germany, France, and Italy. Germany and the United States have made great strides in the race for the world's shipping trade. Germany in 1900 launched the *Deutschland*, the largest and fastest vessel of that time, and in 1914 the *Vaterland* (now *Leviathan*) the largest vessel yet built. In the United States shipbuilding began with fishing-boats. In 1640 a vessel of 300 tons was built at Salem; and soon shipbuilding was a prosperous industry in several New England ports. The revolutionary war was fatal to the industry; but from 1812 to 1850 wooden shipbuilding prospered exceedingly, and the American sailing-vessel reached perfection. The first China clipper was built by Webb at New York in 1841; and the first three-decker by the same builder in 1849. The building of whalers, once a great New England occupation, is almost extinct. The share of the United States in the introduction of steam-power has been already recorded. America is specially famous for her river and lake steamers, the first stern-wheel paddle-boat being built by Fulton and Livingston at Pittsburgh in 1811. The first great lake steamer was built at Sackett's Harbor in 1816; and the first iron boat was built in Pennsylvania for service on the Susquehanna. Shipbuilding in the United States has been handicapped on account of high costs. However, by improvements in the manufacture, Americans were able to make steel plates cheaper than any other makers; hence in 1900 an impetus was given to the industry, many large steamers were built, and new building yards were established not only on the seaboard but on the great lakes (access to the sea being by the St Lawrence). Since 1914, owing to the Great War, the building capacity of every country has been enormously increased.

Shipka, a pass in the Balkans, 50 miles NE. of Philippopolis and 87 miles SW. of Rustchuk on the Danube, was stoutly held by the Russians, in an entrenched camp, against the desperate assaults of Suleyman Pasha (21st to 26th August and 9th to 17th September) in the war of 1877.

Ship-money, an impost levied by Charles I. in 1634-37, which led to fierce opposition on the part of Hampden and the parliament. In old English days royal navies were raised by the levy-

ing of ships; and under the early Norman kings the ports and the counties on the coast were called on from time to time to provide ships and men to strengthen a naval force paid for by the kings. In 1626 Charles's expedition to Cadiz was largely made up of merchant-ships pressed into the royal service; but it was in 1634, when the Dutch and French navies were well able to dispute England's sovereignty of the sea, that Charles set himself seriously to the work of greatly strengthening the English navy. By the advice of Noy, the attorney-general, he issued writs to the port towns to furnish ships, but agreeing to provide the ships if the towns would equip and man them. In 1635 he demanded the like from maritime and inland counties also; agreeing as before to find the ships if money for manning and equipment were provided by the counties. Thus a strong fleet was raised and manned with money which was not sanctioned by any parliamentary grant; and much grumbling was the result. In 1637 Charles consulted the judges, and ten out of twelve declared that the king had a right to do what was necessary for the defence of the kingdom in times of danger. It was agreed that no tax could be levied without parliamentary sanction; but Charles maintained that ship-money was not a tax, but money paid in lieu of the performance of the duty incumbent on all Englishmen of defending their country. John Hampden refused to pay the 20s. levied on his estate in Buckinghamshire, and his case was dealt with by the Exchequer Chamber (for the issue, see HAMPDEN). The Long Parliament in 1640 and 1641 pronounced the levying of ship-money illegal; and the bill to this effect received the king's assent, 7th August 1641.

Ship of Fools: See BRANDT; also BARCLAY (ALEXANDER).

Shipton, MOTHER, a famous propheticess of popular English tradition, whose story has at any rate the weight of a considerable antiquity. S. Baker published in 1797 her prophecies, together with those of the Cheshire prophet Nixon, and here we gather the following circumstantial details. Ursula Shipton was born near Knaresborough in Yorkshire, in July 1488, was duly baptised as Ursula Southiel by the Abbot of Beverley, at twenty-four married Tony Shipton, a builder, and departed this life with much serenity at over seventy years of age. However, a book (1684) by the notorious Richard Head is the real source of most of the fables about her. Here we are told how Agatha Shipton was carried off and married by the devil, how she bore him an ugly impish child, enjoyed power and knowledge beyond the measure of mortals, and left many prophecies behind her. Of these the earliest known record is a pamphlet of 1641, containing formal prophecies of the death of Lord Percy and of Wolsey—her prophecy that Wolsey should never reach York was long current, is given by Baker, and was claimed as fulfilled by the fact that Wolsey was arrested at Cawood, a few days before his formal installation as Archbishop of York. In W. Lilly's *Collection of Ancient and Moderne Prophecies* (1645) occurs 'Shipton's prophecy,' and from it we see that all her prophecies were considered as already fulfilled. Again, an extant comedy on the subject dates from about 1660. A prophecy in doggerel verse under her name was put into circulation about 1862 by Charles Hindley, on his own confession (*Notes and Queries*, April 26, 1873). These wretched lines concluded with a prophecy that the world should come to an end in 1881, which caused great anxiety amongst a few very ignorant persons in corners of England. See William H. Harrison's *Mother Shipton Investigated* (1881), in which all the facts available are

excellently set forth. He points out, moreover, the striking likeness between the traditional Mother Shipton represented on the chap-books and the conventional Punch.

Ship-worm. See TEREDO.

Shipwrecks. See WRECKS.

Shiraz, a city of Persia and capital of the province of Fars, much celebrated in Persian poetry for its climate, its wine and roses, and its beautiful gardens, is situated in a broad plain, 115 miles ENE. of Bushire and 35 miles SW. of the ancient Persepolis (q.v.). It is enclosed by ruined walls, and previous to the earthquakes contained many splendid mosques, bazaars, caravanserais, and other public buildings. The place has now a mean and ruined appearance, and is greatly neglected. The wine of Shiraz, which is very strong and resembles Tokay, is, however, still famous throughout the East. Rose-water is prepared in large quantities. Inlaid articles in wood and metal, glass, and woollens are made here. The city was founded in the 8th century, and from its beautiful situation and charming climate became a favourite resort of the Persian princes. In 1812 a destructive earthquake laid a large portion of it in ruins, and another in 1824, which cost the lives of 4000 of the inhabitants, completed the wreck of its prosperity. It was, however, rebuilt, and numbered 40,000 people, when a third and more terrible visitation, in April 1853, laid almost the whole town again in ruins, and caused the death of 10,000 people. It has since been partially rebuilt in a somewhat inferior style, and its pop. is now estimated at 50,000. The tombs of the poets Hafiz and Sâdi, both natives of the town, are in the neighbourhood.

Shire. See COUNTY.

Shiré, a river of East Africa, which, after a southerly course of 370 miles, joins the Zambezi. Until the hydrographic changes at the beginning of this century, the Shiré flowed out of Lake Nyasa, which now fails to discharge. Consequently, the upper channel of the river has become choked with sand and vegetation, but it has been proposed to dredge it, making the Shiré navigable for lake steamers as far as Matope. It was discovered by Livingstone during the Zambezi expedition (1858-63). Navigation is obstructed by cataracts (Murchison Falls, &c.) for 35 miles, in which the Shiré falls 1200 feet, and elsewhere by increasing shallowness. The river passes through the heart of the Shiré Highlands, where live most of the European inhabitants of Nyasaland. It is proposed to extend the railway from Blantyre through this region to the south-western arm of Lake Nyasa. See NYASA.

Shirley, JAMES, dramatist, was born in London, 18th September 1596, and went at twelve to Merchant Taylors' School, whence he passed in 1612 to St John's College, Oxford. Wood tells us that Laud esteemed him highly, but deterred him from seeking holy orders because of the large mole on his left cheek. He migrated, however, to Catharine Hall, Cambridge, took his B.A. in 1617, was promised in 1618 and obtained in 1621 the mastership of St Albans grammar-school. In 1624 he was one of the proctors for St Albans in convocation, though Wood says he was already Roman Catholic. Finding his mastership 'uneasy to him,' says Wood, 'he retired to the metropolis, lived in Gray's Inn, and set up for a play-maker.' He worked hard in his vocation, being a diligent student of his great predecessors, and Shakespeare alone has bequeathed us a larger number of regular five-act plays—there are as many as thirty-three printed in the edition of Gifford and Dyce. In 1636 or 1637 he went to Ireland, probably under the protection of Lord Kildare, but soon returned to London,

where the suppression of stage-plays in 1642 ended his livelihood. For some time he attended on the Earl of Newcastle, then returned to London again to earn his bread by teaching. He contributed the address 'To the Reader' to the first folio of Beaumont and Fletcher (1647). The Restoration revived his plays, but brought him no better fortunes; and Wood tells us that he and his second wife died on the same day, distracted by the Great Fire, and were buried in the same grave, October 29, 1666.

For his plots Shirley drew upon his own inventiveness, and Dyce points out that not one, if we except that extraordinary failure, *St Patrick for Ireland*, is founded upon events of British history. Beaumont and Fletcher were his models, even more than Ben Jonson, his 'acknowledged master,' but it must be owned he has but little of the grand Elizabethan manner. Most of his plays are tragicomedies, and his best work is ever the tragic and pathetic portions. He is chaste by comparison with his contemporaries, and his plays breathe throughout a pensive and tender beauty that touches a sympathetic reader with a charm of its own. Bright and playful fancy, sweet and flowing dialogue, honest emotion and unwrought pathos—these are the threads out of which his magic robe is woven.

His chief plays were *Love Tricks*, a bright but ill-constructed comedy, though Pepys calls it a 'silly play' (1625); *The Maid's Revenge*, a poor tragedy (1626); *The Brothers*, a comedy (1626); *The Witty Fair One*, an excellent comedy (1628); *The Wedding*, a charming and indeed exquisite comedy (1628); *The Grateful Servant*, a fine tragi-comedy, prefaced by eleven copies of verses by various friends, including Massinger (1629); *The Tractor*, his finest and also his strongest tragedy (1631); *The Changes*, or *Love in a Maze*, a comedy (1632); *The Bird in a Cage*, a comedy (1632, printed next year with a sarcastic dedication to Prynne, then suffering his cruel punishment); *Hyde Park*, a bright comedy, branded by Pepys as 'a very moderate play' (1632); *The Young Admiral*, specially commended by the Master of the Revels as free from oaths (1633); *The Gamester*, an admirable comedy, revived by Garrick in 1758 (1633); *The Example*, an excellent comedy, Sir Solitary Plot a happy imitation of Ben Jonson's characters of humour (1634); *The Opportunity*, an amusing though improbable comedy (1634); *The Lady of Pleasure*, the most brilliant of his comedies (1635); *The Imposture*, a tragi-comedy (1640); and *The Cardinal*, to the author himself 'the best of his flock,' a tragedy coloured by Webster's *Duchess of Malfi* (1641). In 1646 he printed a volume of his poems, including his masque of *The Triumph of Beauty*. As a writer of masques he is second only to Ben Jonson. Among his best was *The Triumph of Peace*, presented by the Inns of Court before the king and queen in 1638. Another, *The Contention of Ajax and Ulysses* (1659), contains the noble and solemn lyric, 'The glories of our blood and state are shadows, not substantial things.' Almost as good is the ode, 'Victorious man of earth,' in *Cupid and Death* (1655), or that beginning 'Ye virgins that did late despair' in his dull play, *The Imposture*. The only complete edition is by Gifford and Dyce (6 vols. 1833). There is a selection, with *The Triumph of Peace*, by Gosse (1888). See biographical and critical studies by Schipper (1911), Forsythe (1915), and (for sources) Nason (N.Y. 1915).

Shirwa, a lake of south-east Africa, 45 miles SE. of Lake Nyasa; length, 40 miles; breadth, 15 to 20 miles; and 1970 feet above sea-level. On the west, between the lake and the river Shiré, Mount Zomba rises to 7000 feet. It was proved by O'Neill in 1884 to have no connection with the river Lujenda, a right-hand tributary of the Rovuma.

Shishak (in hieroglyphs, *Shashank*, the *Susak* or *Susakim* of the Septuagint, the *Shishak* of the Hebrew version, the *Sesonchosis* or *Sesonchis* of Manetho), the name of several monarchs of the 22d or Bubastite Egyptian dynasty (see EGYPT).

Shishak I's name is found in the portico built by the Bnbastite dynasty at the great temple of Karnak, and on several statues of the goddess Sekhmet, which probably came from Luxor. Jeho-boam fled to Shishak from the pursuit of Solomon, who wished to kill him, and on Solomon's death quitted Egypt, and contended with Rehoboam for the possession of the crown. This struggle caused the division of the kingdom of David into two states, those of Israel and Judah. In the fifth year of Rehoboam Shishak marched to Jerusalem with an army of 12,000 chariots, 60,000 cavalry, and an innumerable number of infantry, composed of Troglodytes (?), Libyans, and Ethiopians. He took the city, the treasures of the temple, and all the gold bucklers which Solomon had made. His conquests are recorded on a wall of the temple of Karnak. The god Amon is represented presenting to him lines of prisoners, inscribed with various names of places, amongst which are the Field of Abiam, Beth-shean, Megiddo, Aijalon, Mahanaim, and numerous other towns ostensibly taken by him.

Shittim-wood, the name in the Old Testament for a common and durable wood, believed to be that of some kind of acacia—probably *Acacia Seyal*.

Shoa, a country of Africa, lying to the south of Abyssinia proper, and watered by the Blue Nile and the Hawash, but usually accounted one of the three divisions of the Abyssinian state. Area, approximately 26,000 sq. m. In physical characteristics it closely resembles the rest of Abyssinia (q.v.). The highest point in the Guraghe Mountains reaches 12,790 feet. The people, who are partly Abyssinians and partly Gallas, number about 1½ million. The present capital of Shoa and of Abyssinia is Addis Ababa (60,000); another important place is the former capital, Ankobar (q.v.). This country was conquered by King Theodore of Abyssinia shortly after his accession (1885). On the death of Theodore's successor (John II.) in 1889 the king of Shoa, Menelek, was made king of all Abyssinia; and Shoa naturally became more fully incorporated with the rest of Menelek's dominions.

Shock. It is well known that some forms of injury, as, for example, a blow on the pit of the stomach, may occasion death without leaving any visible trace of their operation in the body; and, indeed, life may occasionally be destroyed even by sudden and powerful mental emotions. In such cases as these death is said to result from *shock*, the actual cause of death being the sudden arrest of the heart's action, consequent on the violent disturbance given to the nervous system. The effects of shock may be manifested in all degrees from the transient feeling of faintness (see FAINTING) or sickness produced by a sudden emotion, or an unexpected and unpleasant sight, &c., to death. In cases of moderate severity the condition known as *collapse* is induced, in which the patient lies in a state of utter prostration, and apparently on the verge of dissolution. The face, and even the lips, are pale and bloodless; the skin is cold and clammy, and drops of sweat are often seen on the forehead. There is great languor and extreme muscular debility, and the sphincter muscles sometimes relax, so that there is involuntary discharge of the contents of the bowels and the bladder. The pulse is quick, and so feeble as often to be almost imperceptible, the blood-pressure in the arteries is extremely low, and the respiratory movements are short and weak, or panting and gasping. The patient is in some cases bewildered and incoherent, in others drowsy, and sometimes almost insensible. In less severe cases nausea and vomiting, with hiccup, are not unfrequent symptoms; and in the case of children convulsions are often present.

When a person recovers from a state of collapse he passes into a condition termed *reaction*, which often lasts for several hours. The first symptoms of this favourable change are improvements in the state of the pulse and the respiratory actions, recovery of the power of swallowing, an increased temperature, and an inclination to move from the supine position to one side. A slight degree of feverishness then often ensues, after which the skin becomes moist, the patient falls asleep, and awakes convalescent. As a general rule, the longer the symptoms of reaction are delayed the greater is the danger, and if several hours pass without any sign of the commencement of reaction there is little hope of recovery.

The principal causes of shock in its severe forms are sudden and severe or extensive injuries, whether due to accident or operation, particularly if they involve any of the viscera, joints, or other organs abundantly supplied with nerves. Pain alone, when intense and protracted, has proved fatal in this way; and it appears in a case related by Sir A. Cooper that sudden relief from great agony was attended by the same untoward result. Certain poisons operate in this manner, depressing the system so suddenly and severely as to produce a state of collapse; tobacco, for example; and drastic purgatives have in some cases induced a similar condition.

The effects of shock are aggravated by loss of blood; and hæmorrhage alone, if sudden and profuse, will produce collapse. General debility and old age favour the influence of the shock, and much depends upon the idiosyncrasy of the patient; an injury which will produce no apparent effect on one man often producing a serious and persistent impression on another.

The following are the most important points in regard to treatment: The patient should be kept in a horizontal position, with the head on the same level as the body, and he should not be raised till decided symptoms of reaction appear. The best stimulants are brandy, given in the form of hot brandy and water, and pituitrin, which raises the blood pressure. At the same time heat should be applied to the pit of the stomach and the extremities, by means of hot flannel, hot-water tins, or, in their absence, bottles containing hot water, and other appliances. The administration of alkaline drinks in large quantity is also important. In severe cases of bleeding, transfusion of blood if available or the infusion into the veins of alkaline fluid or of gum solution is frequently carried out with benefit.

Shoddy (a provincial word, 'that which is shed') formerly meant only the waste arising from the manufacture of wool, but it has acquired a wider and much more important signification. Clippings of woollen and worsted stuffs and rags of any kind of fabric made of wool are now carefully utilised. Cuttings of new flannels, worsted cloths, and knitted textiles receive the name of *new shoddy*, and when articles made of these are worn out they are termed *old shoddy*. On the other hand tailors' clippings of milled cloths are called *new mungo*, while the material of old clothes and rags of this woollen cloth is styled *old mungo*. Both shoddy and mungo, which were formerly, to a large extent at least, waste materials, are now 'ground up' as it is termed—i.e. they are put into a machine with a revolving cylinder armed with iron spikes and having toothed rollers moving in an opposite direction. This *willy* or *devil*, as it is called, reduces the rags or clippings to short wool, which, when cleaned, oiled, and mixed with some fresh wool, is remanufactured into many different kinds of cheap fabrics, such as rugs, druggets, friezes, flannels, inferior milled cloths, &c. These, though service-

able while they last, are of course not so durable as when made of new wool. See RAGS, and WOOL.

Shoebill. See BALANICEPS.

Shoeburyness, on the coast of Essex, and at the mouth of the Thames, faces the Nore, 3 miles E. of Southend and 45 of London. Its dreary marshland, purchased by government in 1842-55, has since been the seat of a school of gunnery, with artillery barracks, batteries, targets, and other appliances for experimenting on cannon. Pop. of urban district, 6500. See GUNNERY.

Shoes. See BOOTS AND SHOES, HORSESHOEING.

Shola, or SOLA, the white pith of the leguminous plant *Eschynomene aspera*, a native of India. With this substance, which is exceedingly light, the natives of India make a great variety of useful articles, especially hats, which being very light and cool are in great request. Helmets made of shola are much used by the British in India.

Sholapur, a town of British India, presidency of Bombay, 150 miles by rail SE. of Poona, with important silk and cotton manufactures. An old fort and ruined walls (in part) still exist. Population (1921) 119,581.—The district has an area of 4556 sq. m. and a pop. (1921) of 742,010.

Shooter's Hill, an eminence (446 feet) in Kent, near Greenwich and Woolwich, which commands a splendid view of London.

Shooting. See GUN, GAME-LAWS, POACHING, GROUSE, DEER-FORESTS, BATTLE, PIGEON, &c.

Shop Acts, a series of acts (1892-1911) consolidated in 1912 and amended in 1913, requiring that on one day a week shop assistants be not employed after 1.30 P.M.; that persons under 18 be not employed more than 74 hours (including meal times) in any week; that shops (with certain exceptions) be closed once a week not later than 1 P.M.; that seats be provided for female assistants; besides providing for meal-hours and for the fixing of closing hours by local authorities. The Shops (Early Closing) Act 1920, amended 1921, requires that (with certain exceptions) shops be closed not later than 9 on Saturdays, and 8 on other nights.

Shore. See SEASHORE.

Shore, JANE, the famous mistress of Edward IV., was born in London, and was well brought up, and married at an early age to William Shore, an honest citizen, traditionally a goldsmith. After her intrigue with the king began her husband abandoned her, but she lived till Edward's death in the greatest luxury, enjoying great power through his favour, yet 'never abusing it,' as More tells us, 'to any man's hurt, but to many a man's comfort and relief.' Her beauty was more that of expression than of feature, and her cheeks somewhat pale, yet her face was fair beyond others, and 'there was nothing in her body that you would have changed, but if you had wished her somewhat higher.' But her greatest charm was her bright and playful wit. After the king's death she lived under the protection of Hastings, and on his death, it is said, of the Marquis of Dorset; but King Richard III., out of a pretended zeal for virtue and to make his brother's life odious, plundered her house of more than two thousand marks, and caused the Bishop of London to make her walk in open penance, taper in hand, dressed only in her kirtle. More tells us that Richard had first tried to charge her with bewitching him, literally rather than in the sense in which she had done his brother, and the reader will remember the use that Shakespeare has made of this in his tragedy of *Richard III.* Jane Shore survived her penance more than forty years, dying in the 18th year of Henry VIII. The additional horrors that she died in a ditch since

called Shoreditch, and that a man was hanged for succouring her contrary to Richard's command, are completely unhistorical, however positive their ballad authority.

Percy printed from the Pepys collection 'The woeful lamentation of Jane Shore,' in wretched doggerel, ascribed to Thomas Deloney. Thomas Churchyard also wrote a poor ballad on the story, inserted in the *Mirror for Magistrates*, and Drayton has in his *England's Heroical Epistles* one from her to her royal lover. Deloney's ballad is printed also in the *Collection of Old Ballads* (1723), with a miserable burlesque song on the same subject. See Mark Noble, in Brayley's *Graphic Illustrations* (1834); and Sir Thomas More's *History of Richard III.* Rowe's drama dates from 1714.

Shorea, a genus of Dipterocarpaceæ (q.v.), about a hundred species of trees ranging from India to the Philippines. From this genus come the woods known as Mercanti and Sál (q.v.), Borneo tallow, and some kinds of Dammar (q.v.).

Shoreditch, a metropolitan and parliamentary borough of London, with two members till 1918, thereafter one; pop. (1921) 104,308. See TOWER HAMLETS, LONDON.

Shoreham, New, a seaport of Sussex, at the mouth of the Adur, 6 miles W. of Brighton. It arose when the harbour of Old Shoreham, now a mile inland, became silted up; it has a tidal harbour, whose piers were erected in 1819. Charles II. embarked here after Worcester for Normandy. The suspension bridge and the Norman and Early English parish church may be noticed. The parliamentary borough of New Shoreham, including from 1770 the Rape of Bramber (177 sq. m. and 42,442 inhabitants in 1881), and returning two members, was merged in the county in 1885. Old Shoreham also has a Norman church. Pop. of Shoreham-by-Sea urban district (1921) 7270.

Shorncliffe, in Kent, 2½ miles W. of Folkestone, the seat of a military camp during the Peninsular war, and since the Crimean war of a permanent one for 5000 men.

Shorthand. The problem which inventors of systems of shorthand have attempted to solve is thus formulated by Peter Bales (c. 1547-1610), a writing-master and stenographer—'to write as fast as a man speaketh treatably.' 'This,' he says, 'may in appearance seem difficult; but it is in effect very easy, containing a many commodities under a few principles, the shortness whereof is attained by memory, and swiftness by practice, and sweetness by industry.' Although three hundred years have elapsed since this assertion was made, it has not yet been realised to the extent anticipated.

The so-called shorthand of the Romans, practised by Tiro, first the slave and afterwards the freedman of Cicero, was really an abbreviated longhand. The Roman letters were shorn of their just proportions, initial letters often served for whole words, and terminations, in which Latin abounds, were either abbreviated or omitted. By systematising these mutilations Tiro constructed a system of swift writing, which served him as Cicero's amanuensis in good stead, and doubtless we owe to it much of what remains to us of the writings of Cicero. Tiro's system, or a modification of it, survived far into the Middle Ages.

The history of shorthand properly so called, with an alphabet of simple signs as substitutes for the ordinary letters, dates from the reign of Elizabeth. Dr Timothy Bright (c. 1551-1615), a learned man, the author of several medical works and the compiler of an abridgement of Foxe's *Book of Acts and Monuments of the Church*, in the year 1588 published *Characterie; an Arte of Shorte, Swifte, and Secrete Writing by Character*. In this ingenious work Bright claims the invention of the art of shorthand.

His claim may justly be disputed, for his system is not shorthand in the present sense of the word. It is not based on a shorthand alphabet, but is a system of arbitrary marks for words: thus /

abound, \ about, | accept, | accuse, | advance, &c.

Two years after the appearance of this work Peter Bales published *The Writing Schoolmaster*. This system also was composed of arbitrary characters. In the year 1602, a little above threescore years before Wilkins published his celebrated *Essay towards a Real Character and a Philosophical Language* (1668), appeared *The Art of Stenography, or Short Writing, by Spelling Character, invented by John Willis, Bachelor in Divinity*. The author intimates in the title of the work the grand distinction between it and the previous attempts that had been made in the art by describing it as 'spelling character,' the others having been verbal character. John Willis's alphabet is:

a b c d e f g h i j k l m n o
A n r | < L J o < > r > u \ (
p q r s t u v w x y z
/ o - | (& v) > x z

The inadequacy of this alphabet is proved by the fact that not one of its letters was used in the same sense by the inventors of systems in the following century, when shorthand began to be popular. Sixteen years after the publication of John Willis' system Edmund Willis published *An Abbreviation of Writing by Character* (1618). This system exhibits a considerable improvement in its alphabet, and 15 of its letters were adopted by subsequent shorthand authors.

The next name on the roll of shorthand authors deserving of mention here is that of Rich, 1654-69. His system was used by Dr Doddridge, who reprinted it for the benefit of his theological students, and strongly recommended its adoption by young persons. Mason followed in 1672-1707. The alphabet had now become much simplified. Mason's system was adopted by Thomas Gurney in 1750, and has since been known as Gurney's shorthand.

The principal shorthand authors of the 18th century who followed conventional spelling more or less, were Macaulay, 1747; Angell, 1758; Byrom, 1767; Taylor, 1786; and Mavor, 1789; and in the early part of the 19th century, Clive, 1810; Lewis, 1815; Moat, 1833; Fancutt, 1840; Bradley, 1843. In the 18th century three systems were published, by Tiffin, 1750; Lyle, 1762; and Holdsworth and Aldridge, 1768; and in the 19th century five systems, by Row, 1802; Towndrow, 1831; Pitman, 1837; De Staines, 1839; and Bell, 1857, all based on the phonetic principle. Of the orthographic systems Taylor's gained most popularity. The following is Taylor's alphabet, with the vowels of Harding's adaptation. Taylor represented all vowels alike by a dot in any position.

b c d f g h j k l m n
/ - - / \) /) - - -
p q r s t v w x y z
| - - - | \ - - -
ch sh th
(- | a - o
- - - e - u
.

The legibility of Pitman's shorthand has led to very general use. A vigorous propaganda and instruction books at low prices have almost blinded the public to the existence of other systems.

The alphabet of Pitman's phonography is:

CONSONANTS.

p b t d ch j k g
(f v th th s z sh zh
(thm) (then)
(l r (up) m n ng w y h

VOWELS.

Long. | ah, | eh, | ee, | aw, | oh, | oo.
palm pate peat pall bone pool
Short. | ä, | ë, | i, | ö, | ü, | öö
pat pet pit poll burn pull

DIPHTHONG AND TRIPHTHONG.

v | ei, | eu, | ou, | ai, | oi, | wi
pine new now ay (yes) boy wide

By adding a hook or small circle to the consonants, by halving, and by lengthening, double and treble letters are produced on the following plan:

/ / / / / / / /
p pl pr sp spr pf pn ps pns pt

Important among later systems are those of Everett, Pocknell, Sloan, Callender, A. H. Browne, Janes, Guest, and Gregg.

An average speaker may pronounce 120 words a minute; a rapid speaker 180, 200, or more. It is impracticable, therefore, for a shorthand reporter to write down every sound uttered. As a rule, a word may be recognised by its consonants alone. Many systems, therefore, adopt the device of omitting vowels except to avoid ambiguity; and in order that the vocalised and unvocalised forms of the same word should not be too unlike, the consonants are contrived to form a framework or 'outline,' to which vowel dots and dashes can be added at pleasure, very much as in the pointing of Semitic writing. Examples are shown above in Harding's and Pitman's vowel-systems; in both cases the position in relation to a consonant determines the value of the vowel-sign. Instead of this, or in supplement to it, other devices are used—as writing the word above, on, or through, the line, according to the class to which its principal vowel belongs; or, as in Pocknell's system (1881), modifying the form of the consonant to indicate a preceding or following vowel. Many systems attempt, but not very consistently, to indicate similarity of sound by similarity of shape. Thus, most of the dental consonants in Pitman's have vertical signs. Voiced and voiceless pairs of consonants may have the same form, written thick and thin (Pitman), long and short (Pocknell), and so on. There has been a tendency in later shorthands to depart from geometrical forms in favour of something more resembling ordinary script. To this class belong Gregg's (1888), Callender's (1889), Sweet's (1892). By including vowels in the word-outline, as is common in script systems, it becomes necessary to omit the end of the word; but, indeed, for reporting purposes, shorthand systems in general find much conventional contraction necessary.

The best-known French systems are those of Prévost and Duployé. Germany has lately adopted for official use the 'Deutsche Einheits Kurzschrift,' based on Gabelsberger and Stolze.

See Isaac Pitman's *History of Shorthand* (new ed. 1913), which describes the ancient systems and 250 English systems; Thomas Anderson's *History of Shorthand* (1883), including the Continental and leading English systems, and his *Shorthand Systems* (1884); and works by Dr Westby-Gibson (1882), J. E. Rockwell, J. W. Zeibig (Dresden, 1878), and H. Moser (Leip. 1889 *et seq.*).

Shorthouse, JOSEPH HENRY, was born at Birmingham in 1834, was educated at private schools, and settled as a manufacturer in his native city. In 1881 the extraordinary popularity of his romance, *John Inglesant* (previously printed for private circulation), carried his name over England. The book was written in fine, delicate English, and revealed a subtle and sympathetic insight into old-world phases of the spiritual mind, but was invertebrate in structure, its second half at any rate anything rather than a novel. It showed, or rather concealed, a consummate skill in adapting and incorporating sentences, sometimes whole pages, from 17th-century books. It was followed by *The Little Schoolmaster Mark: a Spiritual Romance* (1883-84); *Sir Percival: a Story of the Past and the Present* (1886); *A Teacher of the Violin* (1888); *The Countess Eve* (1888); and *Blanche, Lady Falaise* (1891); but none of these stories awoke the same interest as the *magnum opus*. Shorthouse, who (while continuing to manufacture sulphuric acid) wrote also an exquisite introduction to George Herbert's *Temple*, an essay on *The Platonism of Wordsworth*, and a preface to a translation from Molinos, died 4th March 1903. See his *Life, Letters, and Literary Remains* by his wife (1905).

Short-sightedness. See EYE.

Shoshone Falls (pron. *Shoshonee'*), on the Snake (q.v.) River, in southern Idaho, about 950 feet wide, and with a clear leap of 210 feet (that of Niagara is under 170 feet). The river runs in a deep gorge between walls of volcanic rock, 1000 feet high at the foot of the falls, and the head of the falls is in the form of a semicircle. Four miles higher up are the Little Shoshone Falls, two nearly equal cataracts divided by a great rock, and falling 182 feet.

Shoshones, a family of American Indians, also known as Snakes, living, since 1805 at least, to the west of the Rocky Mountains; they are now on three reservations, two in Idaho, one in Wyoming—and scattered through Nevada, Utah, and north-western Idaho. Though most are inoffensive, some of the bands are fierce and warlike, and hostilities ceased only in 1867, after an expedition had destroyed a great part of their braves and stores.

Shoshong, once capital of Khama, chief of the Bamangwato in the Bechuanaland Protectorate, near the telegraph and the railway to Mashonaland, was in 1892 superseded by Palapwe or Palapye, 60 miles to the NE. Shoshong, now deserted by most of its population, was long the largest native town in South Africa, and a great trade centre for ostrich-feathers, ivory, and skins.

Shot is the term applied to all solid projectiles, and more generally to any projectile without a bursting-charge. Although shell-fire from mortars had been used at least as early as 1543, and shell-fire from guns had been tried at various times—notably at the siege of Gibraltar in 1779—the use of shell in guns was not general until, at earliest, the second decade of the 19th century, owing to the lack of a reliable fuse. Consequently the greater

part of artillery warfare on land, and the whole of that at sea (with the rare exceptions when 'bomb' vessels carrying mortars were used in the sieges of sea fortresses), was carried on, up to the date named, with shot of varying kinds—by plain round shot and case shot on land; and by plain round-shot (which were often fired red hot), bar-shot, chain-shot, grape-shot, case-shot, and bags of nails or scraps of old iron, at sea. Bar-shot (two round-shot joined by a bar) and chain-shot (two round-shot joined by a chain) were specially used for attack on masts, spars, and rigging. A grape-shot consisted of a number of small round-shot grouped in layers round a spindle and separated by plates, in order to make a convenient package for loading. It broke up on firing, giving a small shower of balls. Of all these shot, only case-shot is still used. It consists of an iron cylinder full of bullets. The cylinder breaks up on firing and lets the bullets loose. It is used for repelling attack at close quarters. Solid elongated armour-piercing shot has been used for rifled guns, but has been generally abandoned, and the only elongated shot of this kind now used is made of cast-iron, and used for practice. Small shot for sporting purposes is made of lead hardened with antimony or arsenic. The lead is melted and poured through colanders, with holes of varying size, from a great height into water.

Shotts, or SHATS. See ALGERIA; SAHARA.

Shoulder-joint, an enarthrodial or ball-and-socket joint. The bones entering into its formation are the humerus or arm-bone (see ARM) and the scapula or shoulder-blade. The former has already been described; the latter is a flat triangular bone which is indirectly attached to the trunk by articulation with the clavicle. When the arm hangs by the side the scapula covers the ribs posteriorly from the second to the seventh or eighth inclusive. It presents a posterior surface or *dorsum*, an anterior surface or *venter*, three borders, three angles, and certain outstanding processes.

The figure represents a posterior view of the scapula. It is divided into two unequal parts, the supra-spinous fossa (1) and the infra-spinous fossa (2), by the spine (10), a crest of bone commencing at a smooth triangular surface (11) on the internal border, and running across to-

Fig. 1.—Posterior View of the Left Scapula:

The parts designated by the figures 1, 2, 4, 6, 8, 10, 11, 12 are sufficiently described in the text; 3 is the superior border; 5, the external or axillary border; 7, the inferior angle; 9, the internal or vertebral border; 13, one of the nutrient foramina; 14, the coracoid process.

towards the upper part of the neck of the scapula (8), after which it alters its direction, and projects forwards so as to form a lofty arch, known as the acromion process (12), which overhangs the glenoid cavity (6), or receptacle for the head of the humerus. The acromion obviously serves to protect the shoulder-joint, as well as to give great leverage to the deltoid muscle which raises the arm. From

the upper part of the neck (8) there proceeds a curved projection termed the coracoid process; it is about 2 inches long, and gives attachments to several muscles. The upper border of the scapula presents a notch (4), which in the recent state is bridged over by a ligament, and gives passage to the supra-scapular nerve.

The large globular head of the humerus is received into the shallow glenoid cavity of the scapula, an arrangement by which extreme freedom of movement is obtained, while the apparent insecurity of the joint is guarded against by the strong ligaments and tendons which surround it, and above by the arched vault formed by the under surface of the acromion process. As in movable joints generally, the articular surfaces are covered with cartilage, and there is a synovial membrane which lines the interior of the joint. The most important connecting medium between the two bones is the capsular ligament.

The shoulder-joint exhibits the following varieties of motion: (1) flexion, to a great extent; (2) extension, in a much more limited degree; (3) adduction, in an oblique direction, forwards and inwards; (4) abduction very freely; (5) circumduction; and (6) rotation slightly.

The morbid affections of the shoulder-joint may be divided into those arising from disease and those dependent on an accident. The most common diseases are acute and chronic inflammation of the joint, which often terminate in its ankylosis or immobility. The principal accidents are fractures and dislocations. There may be fracture (1) of the acromion process, or (2) of the coracoid process, or (3) of the neck of the scapula, or (4) of the superior extremity of the humerus; or two or more of these accidents may be associated. Again, the head of the humerus may be dislocated from the glenoid cavity as the result of accident in three different directions—viz. (1) downwards and inwards into the axilla, which is by far the most common form; (2) forwards and inwards; and (3) backwards on the infra-spinous fossa, or the dorsum of the scapula. The first of these varieties is of very common occurrence, and everybody should know how to recognise, and even (in an emergency) to treat it. The bones are in the position shown in the figure; the arm is lengthened; a hollow may be felt under the acromion, where the head of the bone ought to be; the shoulder is flattened; the elbow sticks out from the side, and cannot be made to touch the ribs; and the head of the bone can be felt if the limb be raised, although such an attempt causes great pain and weakness. The methods of treating such a case are discussed at DISLOCATION. The scapula may also be fractured in any of its parts as the result of direct violence, and its inferior angle may slip from its natural position.

Fig. 2.—Dislocation of the Shoulder-joint downwards:

- 1, the clavicle, 2, the acromion process; 3, the coracoid process; 4, the glenoid cavity; 5, the head of the humerus lying in the axilla.

Shovel, SIR CLOUDESLEY, a brave but ill-fated admiral, was born of poor parents, about 1650, most probably at Cley, a Norfolk fishing-village. Here he was apprenticed to a shoemaker, but he ran away to sea, and soon rose by his remarkable ability and courage through the grades of cabin-boy and seaman to the quarter-deck. He served as lieutenant under Sir John Narborough in the Mediterranean (1674), burned four pirate ships under the walls of Tripoli, commanded a ship at the battle in Bantty Bay (1689), and was soon after knighted for his conduct. In 1690 he rose to be rear-admiral of the blue, and took an active part in the battle off Beachy Head; two years later, as rear-admiral of the red, he supported Admiral Russell heroically at La Hogue, and himself burned twenty of the enemy's ships. He was sent to Vigo in 1702 to bring home the spoils of Rooke, next served under that hero in the Mediterranean, and led his van at Malaga. In January 1705 he was made rear-admiral of England. That year he took part with Peterborough in the capture of Barcelona, but failed in his attack on Toulon in 1707. On the voyage home his ship, the *Association*, struck a rock off the Scilly Isles, on the foggy night of the 22d October 1707, and went down with 800 men on board. Three other vessels of his squadron perished with a loss of over 2000. Sir Cloudesley Shovel's body was washed up next day, and buried in Westminster Abbey.

Shoveler (*Rhynchaspis* or *Spatula*), a genus of birds of the duck family, Anatidæ, having the hind-toe small, free, and unlobed; and remarkable for the expansion of the end of the mandibles in adult birds, particularly of the upper mandible.

The Common Shoveler (*Rhynchaspis clypeata*), male and female.

The lamellæ of the mandibles are long and very delicate. The legs are placed near the centre of the body, so that these birds walk much more easily than many of the ducks. The Common Shoveler (*R. clypeata*) is smaller than the wild duck, but rather larger than the widgeon. The shoveler is a visitant to the British Isles, especially during cold weather. A few remain all the year. It is widely distributed over North Africa, Europe, Asia, and North America. It is reported as having been found in Australia. Its nest is made of fine grass, with a lining of down, on dry ground on the borders of rushy lakes. The eggs, from eight to fourteen in number, are of a pale greenish buff colour. Its food consists of grasses, worms, slugs, snails, insects, and small crustaceans. Its flesh is well flavoured and very highly esteemed. The bird is often called Broad-bill.

Showers of Fishes occasionally fall in different parts of the world, exciting great aston-

ishment. Instances of this kind have occurred in Britain. On one occasion a shower of small three-spined sticklebacks fell near Merthyr-Tydvil in Wales, sprinkling the ground and housetops over a large area. If caught up by a whirlwind from any of the brackish ponds near the sea, in which this species of fish abounds, they must have been conveyed through the air a distance of almost thirty miles. Another similar instance occurred at Torrens, in the Isle of Mull, in which herrings were found strewn on a hill five hundred yards from the sea, and one hundred feet above it. Such downfalls are more common in tropical countries. In India a shower of fishes varying from a pound and a half to three pounds in weight has been reported. Sometimes the fishes are living, more frequently they are dead, and sometimes dry or putrefying. They are always of kinds abundant in the sea or fresh waters of the neighbourhood. The occurrence of the phenomenon is readily explained by the partial vacuum and strong up-draught produced in the centre of a whirling column of air like that of a Tornado (q.v.). Such a whirling column in passing over the surface of a lake or river or of the sea may suck up a considerable quantity of water along with any living creatures that may be in it. This may be carried for a considerable distance, and is discharged as a waterspout or cloudburst when the rotational energy of the whirl is expended. Showers of frogs (when authenticated) are a similar phenomenon. Showers of dead flies have also been reported. The analogous showers of 'sulphur' or of 'blood' are produced by wind-borne pollen from pine-trees, or minute organisms of fungoid nature and bright red colour. In the latter cases the organic particles probably play the part of dust in causing the rain-drops to form. See BLOOD-RAIN.

Shrapnel, LIEUTENANT-GENERAL HENRY (1761-1842), invented the Shell (q.v.) named after him.

Shreveport, a city of Louisiana, on the west bank of Red River (here spanned by an iron bridge of 1200 feet), and 328 miles by rail NW. of New Orleans, with which it has also regular steamboat connection. It contains oil refineries, iron-works, machine-shops, and has a large export trade in cotton. The cattle trade is also important, and there is some lumbering. Pop. 44,000.

Shrew (*Soricidae*), a family of insectivorous mammals closely resembling, in general form and appearance, the true mice and dormice, but in reality widely differing from and not to be confused with those rodents. The shrews have the head small, muzzle long and pointed, eyes small but well developed, external ears usually small; body mouse-like, covered with hair; limbs short, nearly equal in size, the feet not adapted for digging; tail nearly naked and scaly. The teeth vary in number from twenty-eight to thirty-two; the formula $i. \frac{1}{2} c. \frac{1}{2} p. \frac{1}{2} m. \frac{3}{2}$ shows the numbers of teeth so far as they are constant, *v* meaning that the incisors and premolars in the upper jaw vary in different species. Along the sides of the body, or at the root of the tail, are peculiar glands, which secrete a fluid of a very strong odour. The shrews are very widely distributed, being found over North America and the whole of the eastern hemisphere except Australia. The Oriental region has twenty-eight species, the Nearctic twenty-four, the Ethiopian eleven, and the Palearctic ten. The classification of the shrews is a matter of extreme difficulty. The family is said to consist of one genus, eleven sub-genera, and about sixty-five species.

The Common Shrew (*Sorex vulgaris*), found in the British Isles and over the whole continent of Europe, has a body about $2\frac{1}{2}$ inches long, the fur being generally reddish gray above and grayish below, and a tail about $1\frac{1}{2}$ inch long, four-sided with the angles rounded off, and not tapering. It abounds in dry fields, gardens, and hedge banks, feeding chiefly on insects, worms, and slugs. It burrows and makes long runs just under the surface of the ground. It is very pugnacious, and two shrews rarely meet without one of them being killed and eaten. Its natural enemies are weasels and owls. It is saved from some by an unpalatable secretion from a row of glands along each side of the body. Great numbers of shrews are often

The Common Shrew (*Sorex vulgaris*).

found dead in autumn, and it is believed by some naturalists that the normal length of life is little over a year. The shrew breeds in spring; the female brings forth five to seven young in a nest of soft dry herbage in a hole in the ground. Though harmless and inoffensive, the shrew has long been regarded with dread and aversion (see White's *Natural History of Selborne*, Letter xxviii.). The Lesser Shrew (*S. pygmaeus*), another British species, closely allied to the common shrew, but with a proportionately longer tail and white on the under parts of the body, is the smallest British mammal. The Water Shrew (*Crossopus fodiens*), larger than the common shrew, is not known to occur in Ireland, but is found in Great Britain and over the whole continent of Europe as far north as the shores of the Baltic. Though not absolutely confined to the water-side, it prefers to live there, where it forms its dwelling as a burrow in a soft bank. It feeds chiefly on aquatic insects, molluscs, and crustaceans. The Garden Shrew (*Crocidura aranea*) is common over almost the whole of Europe, but does not occur in Sweden or in the British Isles. The Tuscan Shrew (*C. etrusca*), found in the south of Europe, from France to the Black Sea, and also in the north of Africa, has a body only about an inch and a half long and a tail about an inch, and is the smallest living mammal. The Rat-tailed Shrew (*C. myosura*), known in India as the Musk-shrew or Musk-rat, is about 6 inches long, and has a strong musky odour. The Musk-rat of Ceylon (*Sorex kandianus* or *serpentarius*), a smaller form, is found in Southern India and Ceylon. Two very interesting species have been brought from Tibet—the Tibetan Water Shrew, with sucking discs on the under surfaces of its feet; and the Tailless Shrew (*Anurosorex squamipes*), with a body like a mole, ears entirely concealed, eyes almost imperceptible, and feet short and scaly.

Shrew Mole (*Scalops*), a genus of insectivorous mammals of the family Talpidae, very closely allied to the Moles (see MOLE). The tail is short and naked; the muzzle is long and slender, the nostrils looking forwards and upwards on the oblique slope at the end of the snout; the eyes are very small and are hidden in the fur. The teeth are peculiar in form; their number is represented

by the formula i. $\frac{1}{2}$, c. $\frac{1}{2}$, p. $\frac{1}{2}$, m. $\frac{1}{2}$. The feet resemble those of the common mole, but the toes of the hind-feet are webbed. All the species are American. The Common Shrew Mole, or simply Mole (*S. aquaticus*), is found everywhere in the United States east of the Mississippi. The Prairie Mole or Silvery Shrew Mole (*S. argentatus*), about 7 inches long, is found on the western prairies as far eastwards as Ohio and Michigan. The Texan Shrew Mole (*S. latimanus*), larger in size and possessing broader fore-feet than any other species, is found in Texas and Mexico. Two other shrew moles have been placed in a separate genus: one, Brewer's Shrew Mole (*Scapanus breweri*), closely resembling the common mole externally, but agreeing in its dentition and habits with the star-nosed mole, inhabits the eastern United States; the other, the Oregon Shrew Mole (*Scapanus townsendi*), is found plentifully on the banks of rivers on the Pacific coast.

Shrewsbury, the county town of Shropshire, on the Severn, 36 miles SSW. of Crewe, 42 W. by N. of Birmingham, and 163 NW. of London. The river here makes a serpentine curve and is spanned by the English Bridge (rebuilt 1774), the Welsh Bridge (rebuilt 1795), the iron bow and girder Kingsland Bridge (1882), which lead to the suburbs of Abbey-Foregate, Coleham, Frankwell, Castle Foregate, and Kingsland; and the Greyfriars iron foot-bridge (1879). With its steep, narrow streets, and its wealth of black and white half-timbered houses, Shrewsbury is picturesque as very few English towns. Of its castle, built by Roger de Montgomery, little Norman work remains. The present castle, built by Edward I., was in 1926 bought from Lord Barnard by the Shropshire Horticultural Society, given to the town, and restored as a council chamber. Holy Cross or Abbey Church belonged to a Benedictine abbey (1083). Of the other Anglican churches the chief is St Mary's, Norman to Perpendicular in style, with some fine stained glass and an octagonal spire (200 feet high). Noteworthy also are the Roman Catholic church (1856), by Pugin; the council-house (1501-60), where Charles I. stayed in 1642, and James II. in 1687; the old market-house (1595); the 'Raven' Hotel, where Fairclough in 1705 wrote the *Recruiting Officer*; the 'Quarry,' a pretty park of 25 acres, with its lime-tree avenue (1719); a Doric column (1816) to Lord Hill, 134 feet high; and a bronze statue (1860) by Marochetti of Clive. The county museum and a free library now occupy the old buildings (1630) of the grammar-school, which was transferred to a fine new site in 1882. Founded by Edward VI. in 1551, though not actually opened till 1562, and augmented by Queen Elizabeth in 1571, this school was recognised as one of the seven great public schools in the Public Schools Act of 1868, and owes its greatness largely to the exertions of two successive headmasters, Dr Samuel Butler (1798-1836), afterwards Bishop of Lichfield, and Dr Kennedy (1836-66). Among its alumni have been Sir Philip Sidney, Fulke Greville, Wycherley, Judge Jeffreys, Charles Darwin, Samuel Butler (of *Erewhon*), a grandson of the headmaster), Stanley Weyman, and such famous scholars as F. A. Paley, H. A. J. Munro, and R. Shilleto; a statue of Darwin, in front of it, was unveiled 1897. In 1926 the proposal was rejected to form a new bishopric out of parts of the existing bishoprics of Lichfield and Hereford. Glass-painting, malting, iron-founding, and the making of farm implements are industries; and 'Shrewsbury cakes' have long been held in esteem. Chartered by Richard I., the borough returned two members from Edward I.'s reign till 1885, one till 1918, when it was merged in the county. Pop. (1851) 19,681; (1891)

26,967; (1921) 31,013. The Cymric *Pengwern* ('alder hill'), after its capture in 778 from the king of Powys by Offa of Mercia, changed its name to *Scrobbsbyrig* ('town in the wood'), from which the modern name is derived. Thenceforward it has figured often in history, having been repeatedly besieged—e.g. by Llewellyn (1215), and the parliamentarians (1644). In the battle of Shrewsbury, fought at Battlefield, 3 miles NE., on 21st July 1403, Henry IV. (q.v.) routed Hotspur and his confederates. For the earls of Shrewsbury, see TALBOT, and SHEFFIELD.

See works by T. Phillips (1779), Owen and Blakeway, Pidgeon, W. Phillips, Fisher (1899), and the 'Victoria History' of Shropshire (1908).

Shrike (*Lanius*), a genus of passerine birds having the bill short and compressed, the upper mandible curved and with a prominent tooth, the base of the bill covered with hairs directed forwards, wings of moderate length, and very powerful feet. They are found in all parts of the world except in South America. They are called Butcher-birds from the habit, common to many species, of impaling their prey upon thorns. The food consists chiefly of insects, but often also of mice, frogs, lizards, and small birds. The Great Gray Shrike

Great Gray Shrike (*Lanius excubitor*).

(*L. excubitor*) visits the British Islands in autumn and winter, but has not been known to breed. It is one of the largest species, its length being 9 to 10 inches. The back is of a light gray colour, wing and tail feathers black tipped with white, bill and legs brownish black. The Lesser Gray Shrike (*L. minor*) has also been seen in England; but the commonest British species is the Red-backed Shrike (*L. collurio*), which breeds in wooded districts in England and Wales, and occasionally in the south-east of Scotland. The nest is made of twigs and roots, neatly lined with wool and hair. Only one brood is reared, and the birds usually migrate in August. The males of this, and of some other species, have considerable power of song. In Australia the shrikes are represented by the nearly allied Thickheads (*Pachycephala*), which abound in the forests throughout that continent and Oceania.

Shrimp (*Crangon*), a genus of crustaceans, of the order Decapoda, allied to lobsters, crayfish, and prawns. The form is elongated, tapering, and arched as if hunchbacked. The beak is very short, affording a ready distinction from prawns. The forceps are comparatively small. The whole structure is very delicate, almost translucent; and the colours are such that the shrimp may readily escape observation, whether resting on a sandy bottom or swimming through the water. For the change in colour on boiling, see PIGMENTS OF ANIMALS.

The quick darting movements, like short leaps betray them to any one who looks attentively into a pool left by the retiring tide on a sandy shore. When alarmed they bury themselves in the sand by a peculiar movement of their fanlike tail. The Common Shrimp (*C. vulgaris*) is very abundant

Common Shrimp (*Crangon vulgaris*).

on British and other European coasts wherever the shore is sandy. It is about 2 inches long, of a greenish-gray colour, dotted with brown. It is in great esteem as an article of food, and is generally taken by a net in the form of a wide-mouthed bag, stretched by means of a short cross-beam at the end of a pole, and pushed along by the shrimp wading to the knees. Sometimes a net of larger size is dragged along by two boats. The Skeleton-shrimp or Spectre-shrimp is a small crustacean of the family Caprellidæ (e.g. *Caprella linearis*). The Brine-shrimp (q.v.) is the subject of a separate article. The so-called Fresh-water Shrimp is treated at GAMMARUS.

Shrine, a case or reliquary for containing the Relics (q.v.) of saints and martyrs.

Shropshire, or **SALOP**, a West Midland county of England, on the Welsh border, bounded by the counties of Cheshire, Stafford, Worcester, Hereford, Radnor, Montgomery, and Denbigh. It measures 50 miles by 41, and has an area of 861,800 acres or 1347 sq. m. The Severn, entering from Montgomeryshire, winds 55 miles across the interior, dividing Shropshire into two pretty equal portions, and being joined here by the Tern, whilst a lower tributary, the Teme, traces much of the southern boundary. Ellesmere (116 acres) is the largest of several lakes. The northern and eastern portion, to the left of the Severn, is level with the exception of the isolated Wrekin (1320 feet), and is occupied by the New Red Sandstone. The southwestern portion, belonging to the Old Red and earlier formation, is rugged and mountainous, and in the Cleve Hills attains 1805 feet. Coalbrookdale till exhausted was its chief coalfield. The mineral wealth also includes iron, lead, zinc, limestone, and freestone. The soil is variable, but generally fertile and well cultivated. Much attention is paid to live-stock. The county is divided into 14 hundreds. It contains the municipal boroughs of Shrewsbury (the county town), Bishop's Castle, Bridgnorth, Ludlow, Oswestry, and Wenlock. It returns four members for the Oswestry, Shrewsbury, Wiekln, and Ludlow divisions. Clive was a native; and historic scenes or antiquities, other than those noticed in the articles on the different towns, are Acton-Burnell, Boscobel, Wroxeter, Watling Street, and Offa's Dyke. Pop. (1801) 169,248; (1841) 225,320; (1871) 248,111; (1891) 236,339; (1901) 239,321; (1921) 242,959.

See works by Hulbert (1837), Lloyd (1844), Eytton (1853-60), Anderson (1864), Mrs Acton (1868), Walcott (1879), Miss G. Jackson (Dialect, 1879-81), Miss C. Burne (Folklore, 1883-85), A. J. C. Hare (1899), and Watts (1919), and the 'Victoria History.'

Shrovetide, 'shriving-time,' 'absolution-time,' the name given to the days immediately preceding

Ash-Wednesday, which, as indeed the whole period after Septuagesima Sunday appears to have been, were anciently days of preparation for the penitential time of Lent. In the modern discipline of the Roman Catholic Church a trace of this is still preserved, as in many countries the time of the confession, which precedes the paschal or Easter communion, commences from Shrovetide. These days were sometimes called Fasting-tide, Fast-mass, Fasten-e'en, or Fastern's-e'en, names still retained in some parts of Great Britain, as *Fastnacht* is the regular German name. The name of Shrovetide was retained in England after the Reformation, although the practice of shriving was abandoned. The duty of confession having been fulfilled, the faithful, upon the eve of entering upon the Lent, were indulged with permission to give themselves up to amusements and to festive celebrations, of which the counterpart is still seen in the continental carnival. In England the pastimes of football, cock-fighting and throwing at cocks, bull-baiting, &c. were long recognised usages of Shrovetide; and the festive banquets of the day are still represented by the pancakes and fritters from which Pancake Tuesday took its name, and by the 'collops' which gave its title to Collop Monday. Shrovetide cakes and ale, the last surviving relic of Shrove Tuesday celebrations, were discontinued by Brasenose College in 1887. The *Mardi Gras* of the French, with its merry-makings, is Shrove Tuesday. It is a popular festival at New Orleans.

Shrub. See RUM. For Shrubs, see TREES.

Shuckford, SAMUEL, Rector of All-Hallows, London (died 14th July 1754), is remembered for his *Sacred and Prophane History* (4 vols. 1727), intended as a continuation of the work of Prideaux (q.v.).

Shumla, or SCHUMNA, a city of Bulgaria, by rail 56 miles W. by N. of Varna and 80 S.E. of Rustchuk, is of exceptional strategic importance. Its strong detached forts and fortified camp were to have been demolished according to the Berlin treaty, though the clause stipulating this was not carried out. The treaty of Bukarest (1913) again provided that they should be demolished. Shumla is a straggling place, and has numerous mosques and churches, the splendid mausoleum of Hassan Pasha (18th century), an arsenal, barracks, and a military hospital. It manufactures slippers, clothing, copper wares, and silks. Pop. 24,000. The fortified works were attacked in vain by the Russians in 1774, in 1810, and in 1828, but were abandoned to them in 1878.

Shusha, a town of Azerbaijan, 65 miles SSW. of Elisavetpol, occupies a strong position on a mountain, which is accessible only on one side, and is, moreover, defended by a citadel. Pop. 40,000, who make celebrated carpets and coarse silk goods, and trade in horses that are held in great repute.

Shuster, a decayed city of Persia, stands on the Karun, at the point where that river emerges from the hills, 250 miles W. by S. of Ispahan. It is protected by a citadel. It has been identified by some with the ancient city of Susa, but the site of that city is Sus, 40 miles WNW. of Shuster. Pop. 18,000.

Shute, JOHN. See BARRINGTON.

Shwan-pan, the Chinese Abacus (q.v.).

Siah-posh ('black-clothed'), a name given by their Moslem neighbours to the pagan Kafirs of Kafiristan (q.v.).

Sialagogues are substances which increase the secretion of saliva. They may do so by stimulating the secretory nerves of the salivary glands reflexly through the sensory nerves of the mouth, stomach, eye, or nose. Thus, sweet or slightly irritating

substances in the mouth provoke a secretion of saliva, while the sight or smell of savoury eatables 'makes the teeth water.' These are known as topical sialagogues, and include such substances as mustard, ginger, pellitory-root, dilute acids, &c. Dilute acids and pellitory-root are the only ones which are much used in medicine to increase the flow of saliva and keep the mouth moist; a small piece of the latter is chewed from time to time. Sialagogues also act after absorption into the blood by a direct stimulating action on the secretory nerves. Jaborandi and mercurial compounds are well-known examples of this class. The former, or its alkaloid, pilocarpine, may cause the secretion of a pint or more of saliva within a short time after administration. This class is known as remote or direct sialagogues.

Sialkot, a town in the Punjab, near the left bank of the Chenab, 72 miles N. by E. of Lahore, is a rapidly growing, clean, and well-built town, with large manufactures of paper and a native cloth. There are an old fort, gallantly held by a few Europeans in 1857, but now converted into public offices, several shrines sacred to the Sikhs and the Mohammedans, the Punjab military prison, a public garden, and a Christian mission college and schools. Pop. (1881) 45,760; (1921) 70,619, including the cantonment, a mile to the north.—The district has an area of 1796 sq. m. and a pop. of (1921) 937,823.

Siam (native names, *Sayam*, *Muang-Thai*, 'the Land of the Free'), a kingdom of Asia, bounded on the west and partly on the north by Burma, partly on the north and on the east by French Indo-China, and on the south by Cambodia, the Gulf of Siam, and the British Malay States. Its extreme length extends some 1100 miles from about 5° N. to 20° N. lat., and its extreme breadth some 510 miles from about 96° E. to 106° E. long. The frontiers have been the subject of much negotiation, but the area of the present kingdom is 200,148 sq. m. In 1854 Pallegoix estimated the population at 6,000,000, but according to the census of 1919-20 (the first complete census having been made in 1909) the population amounted to 9,207,355, of whom Siamese and Laos each numbered over a third, with half a million Chinese, and numbers of Malays, Cambodians, Burmese, &c., and various hill-tribes. In the capital, Bangkok (630,000), there are large numbers of foreign Asiatics and about 2000 Europeans and Americans. Other towns of importance are Chiang-mai (30,000), Phuket (30,000), and Ayuthia (12,000), the former capital.

The general aspect of the country is that of a plain sloping south and east from the enormous range of limestone resting on sandstone, which extends along the west and broadens out at the north. About three-quarters of the total area is forest, jungle, marsh, or generally uncultivated and uninhabited. The kingdom can be divided into four parts. Northern Siam is cut north and south by forested mountain-ranges, anything up to 5000 feet, with peaks of which Doi-Intanon (8450) is the highest, and is watered by the four rivers, the Meping, Mewang, Meyom, and Menam, which form two streams and then unite at Paknampoh. This united river, about 140 miles in length, and known as the Menam, flows through Central Siam, a vast fertile plain, and enters the sea at Bangkok. In this district are concentrated about nine-tenths of the population. Eastern Siam, surrounded on three sides by French Indo-China, is unproductive and inhospitable, while Southern Siam, in the Malay Peninsula, is much the most beautiful part of the kingdom. The rivers form the principal trade-routes, and in and around Bangkok there is

an intricate network of canals. The united Menam is navigable for steam-launches and other deep-draft vessels. The Pasak is a tributary of the Menam, while the Meklong and the Bangpakong rivers enter the Gulf of Siam direct. The Nam-Mun flows into the Mekhong (q.v.), which for part of its course forms the eastern frontier of Siam, but is never wholly in Siamese territory. Navigation on the Mekhong for vessels of any size is impeded by rapids, and, commercially speaking, this magnificent river is of little importance.

The Gulf of Siam, an arm of the China Sea, is bounded on the N. and W. by Siam, and on the E. by Cambodia and Cochinchina. At its entrance it is 250 miles wide, and it extends nearly 400 miles inland.

Central and Southern Siam, tempered by sea-breezes, are comparatively healthy for the tropics. In the former the maximum and minimum temperatures are about 100° and 55° F., while in the latter the extremes are not nearly so great. In Northern and Eastern Siam, however, intense heat during the day is followed by extreme coolness at night. The annual rainfall ranges from nearly 100 inches in the south to 60 inches in the north, the wet season varying in different parts of the country. The flora (almost entirely tropical) and the fauna resemble those of Burma (q.v.) in the north and of Malaya (see MALACCA) in the south. The famous white elephants are not now regarded with any special veneration.

Agriculture and fishing are the two main industries of Siam. Rice is easily the most important product, forming at once the staple food of the people and the principal article of export: about 6½ million acres are under cultivation, but the methods of ploughing, &c., are mostly still very primitive. Coconuts, pepper, tobacco, and cotton are grown, and betel-nut palms are found in most districts, but, generally speaking, the natural resources of the country are not nearly utilised to their fullest extent. Irrigation is practised everywhere, often in ways that are both primitive and inadequate. In 1924 the first big government irrigation scheme—the Prasak South Canal project in the province of Ayuthia—was completed at a cost of about 1½ million sterling, and other similar projects are under consideration. The number of live-stock, bullocks and buffaloes, &c., is very considerable.

Sea and inland fishing are both very productive, large quantities of 'pla tu,' a kind of pilchard, carp, eel, &c., being caught with nets, traps, rods, and other devices. There is not much hunting, but tame elephants are employed for travelling and for labour, especially in the teak forests in the north, which are among the most valuable in the world. The teak-cutting is mostly in British hands, and the logs are floated down the rivers to Bangkok. Rosewood, boxwood, ebony, and sapan are also found, but are not exploited to any extent. The chief mineral resource is tin, which is mined in Southern Siam, the annual output amounting to between 7000 and 8000 tons. There are a few gold and precious stone workings, and wolfram is also extracted. There are many important rice-mills, especially in the region of Bangkok, but the Siamese are not really a manufacturing people.

Most of the trade passes through Bangkok. The principal imports are cotton goods, food stuffs, metal manufactures, cotton yarn, and tobacco, while more than two-thirds of the exports are accounted for by rice, teak being also very important. It is calculated that in a good year as much as 1½ million tons of rice are available for export, some of it being the best in the world.

A British official occupies the post of financial adviser. The foreign banks in Bangkok have

not yet secured the confidence of the Siamese peasant.

There are about 1550 miles of railway, the main routes extending from Bangkok to Korat in the east, to Chiang-mai in the north, and to the Malayan frontier in the south, in direct communication with Singapore. Various extensions are under construction, but still about three-quarters of the produce of the country is carried by water to the markets. Good roads are found in the neighbourhood of the capital and in Southern Siam.

There is universal liability to military service from the age of twenty-one, but there are many exemptions, and only a final selection is made. The service is for two years with the colours, and for twenty-two years in the three reserves, with maximum services in the latter of a few weeks per annum. The peace and war footings number 30,000 and 100,000 of all ranks respectively. There is a small navy.

The prevailing religion is Buddhism, but there are a few Mohammedans and Confucianists. It is incumbent on every sincere Buddhist to become a lay-monk for a minimum period of three months, but there are supposed to be some 120,000 regular Buddhist priests in Siam, over 8000 monasteries (*wats*), and over 15,000 temples. Some of the Brahmin customs are observed in modified forms, and there is a considerable amount of 'spirit' worship. There are many monastic and local schools, government primary and secondary schools, as well as royal academies, technical colleges, private and foreign mission schools, &c. The university at Bangkok was opened in 1917. Owing to the absence of technical books in the vernacular, English was chosen as the official language for scientific study.

The monarchy is absolute and hereditary in the male line, though formerly the sovereign chose his successor. In 1892 ten chief departments of state were created; now the cabinet, nominated by the king, consists of twelve members, many of whom belong to the royal house, and the more important departments have European advisers. There is also a legislative council, a kind of privy council. The kingdom (outside Bangkok, which is controlled by a lord prefect) is divided into seventeen districts or *monitions*, administered by lord-lieutenants with complete control, deriving their authority direct from the king. Titles are not hereditary, but are usually conferred together with some office of state. Extra-territorial jurisdiction for nationals of some countries is being gradually superseded as the codification of Siamese law slowly proceeds.

The north and east are occupied by Laos or Shans (q.v.), who are tattooed, and differ somewhat in speech from the Siamese; they are, however, descended from the same stock, and the two branches are even now in course of slow assimilation. The character of the Siamese is essentially rustic, peaceful, and indolent. They are very social, patriotic but vain, and fond of bright dresses and jewellery. Their intercourse with each other is conducted with a ceremonious attention to distinction of rank. They are a small, well-proportioned race, with olive-coloured skin, black hair, and are usually beardless. They shave the heads of their children, with the exception of a tuft on the crown, which is cut off with great ceremony at the age of puberty, whereupon the hair is then allowed to grow in the usual fashion. The national dress both for men and women consists of a bright-coloured *panung*—a cotton or silk cloth arranged somewhat in the form of Turkish trousers, and reaching to the knee. Princes and well-to-do people wear in addition a white jacket, often with gold or silver buttons, shoes, and white stockings,

while the women are distinguished by a gaudy scarf thrown across the bosom. The Lao women wear the *sin*, a kind of skirt, but European costume is being adopted in the towns and among the upper classes. The houses of the common people are built of wood or bamboo, thatched with the leaf of the attap palm, and are raised a few feet from the ground on piles. Both sides of the river at Bangkok (q.v.) are lined for several miles with houses floating on wooden pontoons or on bundles of bamboo. Furniture there is none, unless a mosquito-net, a mat or two, and cooking and betel utensils be reckoned furniture. Bangkok, however, is now rapidly becoming an orderly and well-laid-out masonry-built city. The food of the mass of the people consists simply of rice, curry stuff, fish, and fruit. Large quantities of tea are consumed in Chinese fashion without sugar or milk. A spirituous liquor is distilled from rice, but drunkenness is rare. Betel-nut chewing and tobacco-smoking are universal. Betel-nut discolours the teeth, and this process is often aided by the use of various materials to render them quite black and polished. The characteristic vice of the Siamese is gambling, which was carried on in the licensed government gambling-houses, now abolished. At the new-year holidays (in April), and on two or three other public holidays, the people are allowed as a privilege to gamble at home or in the streets.

Marriages are negotiated by elderly women, who find out if the birthdays of the intended bride and bridegroom are suitable—for the Siamese are superstitious in this respect—and arrange the amount of property or money the parents on each side are willing to give to set up the young couple in life. The marriage ceremonies, which are in reality purely domestic, last two or three days, and all friends are entertained liberally during this time. Priests are sometimes engaged to recite prayers, the bride and bridegroom are sprinkled with consecrated water, and on a favourable astrological day—generally the third—the marriage-bed is prepared by an old couple, friends of the family who have in their time been blessed with a large and prosperous family. Among the poorer classes there is little ceremony. The main feature of the contract is that the swain hands over to his mother-in-law a certain sum of money, which is termed 'ka nam nom,' or price of the mother's milk. Polygamy is fairly general amongst the wealthy and noble classes, but only the first wife wedded according to the solemn betrothal holds the rank of legitimate spouse. Systems of medicine are still very curious, and patients are accustomed to take medicines compounded of the most startling ingredients and in enormous quantities. It is a painful custom of obstetrics that after the birth of a child the mother lies thirty days roasting before a hot fire. The number of days is diminished with the number of children. The dead, after being kept for a period varying from two or three days for a poor man to nine or twelve months for a king, are cremated with much ceremony and at great expense.

Twentieth-century progress has been both rapid and thorough, especially under Rama VI. Slavery no longer exists; the old forced labour has been replaced by a poll-tax, not excessively heavy; corruption and waste in the public services are being resolutely attacked; while the position of women has been considerably improved. Western institutions, such as that of the Boy Scouts, and games, especially football, are very popular. The court has given the lead to all improvements, but many of the country districts are still very backward. A prominent feature of past Siamese history has been the important position taken by the foreigner. Mostly all the middlemen in business, the small capitalists, the artisans, and hand-workers

are Chinese, while British, Americans, French, Danes, Belgians, and Germans have assisted (and, in some cases, still are assisting) in the government and development of the country.

History—The Siamese and the Laos are members of the Tai family, which originally belonged to Tibet. Expelled finally from China in the 13th century, they poured into the Indo-Chinese plain, driving the Annamese and Cambodians before them. Authentic Siamese history, however, does not begin till the year 1350, when Ayuthia (q.v.) was founded. Cambodia was conquered and made tributary in 1532. The period from 1659 to 1688 was rendered illustrious by the career of Constance Falcon (or Phaulkon), a Greek of Cephalonia, who attained the dignity of prime-minister. He was the king's favourite, and induced that monarch to send an embassy to Louis XIV. Ayuthia remained the capital till 1768, when after a siege of two years it was taken and burned by the Burmese. The invaders were finally driven from the country by a general named Phaya Tak, son of a Chinese by a Siamese mother, who made Bangkok the capital, and afterwards ascended the throne. The present dynasty was founded in 1782 by another successful general, Phaya Chakkri.

Portuguese traders in the 16th century were followed by the Dutch in the 17th, but the first treaty between Britain and Siam was only signed in 1826. After Sir John Bowring's successful mission in 1855 a consul was appointed, and other nations followed the British example. Numerous frontier disputes with France at the beginning of the 20th century were amicably settled, not altogether to the advantage of Siam. Extra-territorial jurisdiction was abandoned by Britain in 1909 and by the United States in 1922. Under the enlightened rule of Rama V. (1868-1910) and Rama VI. (1910-25), Siam has made enormous progress in the face of many difficulties, financial and other, while the declaration of war against Germany in 1917 greatly strengthened her position and prestige.

Art and Literature.—The Siamese practise bronze-casting, silver-work, and all kinds of lacquer-work. Owing to the influx of foreign productions at the end of the 19th century, the native arts rather declined, but there are signs of a revival. Owing to the damp climate and the luxuriance of the vegetation, few ancient and deserted buildings have survived, and the only modern buildings of any import are the temples and palaces, whose gilded minarets, multiple roofs, and quaint pagodas draw forth the admiration of the stranger on his arrival at Bangkok. As a nation the Siamese are musical, interested in poetry, and are extremely fond of the native plays, which are highly conventionalised and include much dancing. The Western drama is coming into favour. Siamese literature is comprised in some volumes of mythology, history, laws, astrology, &c., of no particular value. The sacred books are written in Pali. The Siamese alphabet consists of forty-four characters and thirty vowel-signs. The language is monosyllabic and has five tones, which render its acquisition difficult to Europeans. The vocabulary is enlarged, either by joining two or more Siamese syllables or by borrowing from foreign languages. Etiquette is strictly observed in the various forms of address between superiors and inferiors, and the court language for the use of royalty is entirely different from that of the common people. The Lao language is more a dialect of the Siamese than a separate tongue.

There are general descriptions of the kingdom of Siam by La Loubère (1691), Kaempfer (Eng. trans. 1727; new ed. 1906), Pallegoix (1854), and Bowring (in Eng. 1857); books of travel by Mouhot (1864) and Coit (1867)

in English, by Bastian (1867) in German, and by Paire (1892-1902) in French; for history see Fournereau, *Le Siam ancien* (1895-1908), Geimi, *Siam's Intercourse with China* (1906), and the work by W. A. R. Wood (1926); for religion, Alabaster, *The Wheel of the Law* (1871); for general information, Warrington Smyth, *Five Years in Siam* (1898), books by Campbell (1902) and Carter (1904), P. A. Thompson, *Lotus Land* (1906, for Southern Siam), R. le May, *An Asian Arcady: the Land and Peoples of Northern Siam* (1926), and the work by W. A. Graham, which is indispensable (3d ed. 1924); see also Raynal, *European Trade with the East*, (1777), Crawford, *Journal of Embassy* (1828), Leon-owens, *English Governors at the Siamese Court* (1870), Gormi, *The Tonsure Ceremony* (1893), Clifford, *Further India* (1904), and Jottrand, *Au Siam* (1905); there is a Bibliography of Siam collected by Satow (1885), and grammars and dictionaries by Pallegoix (1850), M'Farland and Frankfurter (1900).

Siamese Twins, a name given to two children, Eng and Chang, born of Chinese parents in Siam, in 1811, having their bodies united by a band of flesh, stretching from the end of one breast-bone to the same place in the opposite twin. A union of the bodies of twins by various parts is not an unusual occurrence (see MONSTROSITY). The Siamese twins, purchased of their mother at Mek-long, were brought to America by Mr Hunter in 1829, and to England afterwards. After realising a competence by the exhibition of themselves in the various countries of Europe, the Siamese twins settled in one of the southern states of America, where they were married to two sisters, and had offspring. Ruined by the civil war in America, the Siamese twins again made the tour of Europe, and exhibited themselves in London again in 1869. They died 17th January 1874, the one surviving the other two hours and a half only, and then dying from the effect of the shock on a heart already weak.

Sibbald, Sir Robert, Scottish naturalist and antiquary, was born of Fifeshire ancestry at Edinburgh, 15th April 1641. Educated at Edinburgh, Leyden, and Paris, he settled in 1662 as a physician in Edinburgh, devoted much time to botany and zoology, and aided Sir Andrew Balfour in establishing a botanic garden. He was knighted in 1682 and appointed Geographer-royal for Scotland, in 1686 was for a short time a convert to Roman Catholicism, and died about 1722. He published many pamphlets on medical subjects, natural history, Scottish history, and antiquities.

His writings include *Scotia Illustrata, sive Prodromus Historiæ Naturalis* (1684); *Collection of Several Treatises in Folio Concerning Scotland, as it was of Old, and also in Later Times* (1707); *A History of Fife and Kinross* (1710); and his *Autobiography* (1833).

Sibbes, Richard, Puritan divine, was born the son of an honest wheelwright at Tostock (not Sudbury), Suffolk, in 1577. He was put to Bury school, and afterwards, by the exertions of some friends who saw his promise, was sent to St John's College, Cambridge, as sub-sizar. He graduated B.A. in 1599, was elected Fellow two years after, and was Trinity Lecturer from 1610 till 1615, when he was deprived, as also of his fellowship. But he was at once appointed preacher of Gray's Inn, where he laboured till 1626, when, after declining Usher's offer of the provostship of Trinity College, Dublin, he was made Master of Catharine Hall, Cambridge. He was under the suspicion of Laud, but contrived to escape the penalties inflicted by his courts, and in 1633 was appointed by the king Vicar of Trinity Church. He died 5th July 1635. For his heavenly-mindedness he has been called, and not inappropriately, the English Leighton. Among his many books may be named the *Bruised Reed*, which converted Baxter at fifteen; the *Soul's Conflict*, which Izaak

Walton bequeathed to his son, as he did the former to his daughter; *Bowels Opened; The Returning Backslider*, &c. There is a complete edition in Nichol's Puitan Divines, with a Life by the Rev. A. B. Grosart (7 vols. 1862-64).

Sibelius, JAN, Finnish composer, born at Tavastehus in 1865, studied music at Helsingfors Conservatoire (where he became a professor in 1893), and also in Berlin and Vienna (1889-91). He visited England several times and America in 1914. His principal compositions comprise a series of orchestral works—*The Swan of Tuonela*, *Lemminkäinen*, *Pohjola's Daughter*, &c.—inspired by the Finnish national epic *Kalevala*, the suites *Karelia* and *Pelleas et Mélisande*, the tone-poems *Finlandia* and *The Bard*, some chamber music and seven symphonies, of which the last four (1912, 1915, 1923, and 1925) represent the high-water mark of his achievements. Sibelius frequently employs the idiom of the Finnish national music without directly using any folk-song material, but his vivid imagination and his profound grasp of technical resources combine to make his output of the greatest importance. His music is both wild and austere.

Siberia (*Sibir*), originally the name of a Tatar fort on the Irtysh, has now come to be applied to the huge stretch of country in northern Asia, under the rule of the Soviet Republics of Russia; it is bounded on the west by the Urals (though, politically, the 'Ural Region' includes some of the western slopes), on the north by the Arctic Ocean, on the east by the seas of Behring, Okhotsk, and Japan, and on the south by Manchuria, Mongolia, and the Kirghiz or Cossack Republic. The area of this region is calculated at 4,831,882 sq. miles, i.e. considerably larger than that of the whole of Europe.

Physical Features.—(See ASIA.) Large parts of this territory are still but very imperfectly mapped, especially in the wildernesses of the north and north-east—a few surveys along the chief rivers and lines of communication being the only sources of information. The great plateau of eastern Asia enters Siberia to the east of Lake Baikal, where it attains a height of from 3000 to 4000 feet and a width of nearly 1800 miles, and stretches therefrom, with a gradually decreasing height and width, towards the north-eastern extremity of Asia at the Behring Strait. It is fringed on its south-western border by the Great Altai and Sayan mountains, which separate Siberia from North-west Mongolia, the Barguzin and the South Muya ridges, and a series of yet unexplored and unnamed ridges stretching farther north in the same direction; while along its south-eastern border it has the Stanovoi Mountains, which rise as a high wall on the coast of the Sea of Okhotsk, and are continued farther south by the Great Khingan. The border-ridges of the lofty plateau are the highest in Siberia, and their peaks attain heights of from 7000 to nearly 11,000 feet, but very few of them penetrate into the region of perpetual snow. Mountains remaining snow-clad all the year round and giving origin to glaciers are met with only in the Altai (q.v.), at the Munku-Sardyk which rises to a height of 10,700 feet amongst the Sayan Mountains to the south-west of Lake Baikal, and in the highlands of the far north-east. In the remainder of Siberia, owing to the dryness of climate, and also perhaps to a warm current flowing in the upper strata of the atmosphere, the perpetual snow-line stands at a great height not attained by peaks 7000 to 9000 feet high. A broad belt of alpine tracts fringes the plateau along its north-western border, assuming a more and more gloomy aspect in proportion as they advance farther north. The whole of this belt is

thickly clothed with forests, the summits only of the higher peaks (4500 to 7000 feet) rising beyond the limits of tree-vegetation. The auriferous regions of the Altai, Upper Yenisei, Barguzin, and Olekma are situated in this alpine belt. A belt, nearly 500 miles wide, of high plains 1700 to 2500 feet above the sea-level spreads all along the base of the alpine belt, their outer limit being, roughly speaking, a line running from Tomsk towards the north-east. They are very fertile in the south, but of course become less and less suitable for agriculture as they advance into higher latitudes. The whole of West Siberia, between these high plains and the shores of the Arctic Ocean, is an immense lowland which has barely a few hundred feet of altitude and most of which must have emerged from the sea at a quite recent post-glacial epoch. The southern part of these lowlands—the prairies of Ishim, Upper Tobol, and Baraba—is extremely fertile. The soil is a thick layer of black earth, which also penetrates into the lower valleys of the Altai, and the traveller finds there to his astonishment a territory, nearly as large as Great Britain, entirely covered with a luxurious grass-vegetation, with masses of deciduous forest, which has been well called the granary of Siberia. About one-third of the population of Siberia is gathered on these prairies, which are more thoroughly Russian than many parts of European Russia itself.

Farther north, and especially in the space between the Ob and the Irtysh, the country assumes a quite different character; there begin the *urmans*, or immense marshes which cover nearly 100,000 sq. m., entirely clothed with thickets and meagre forests, and quite impracticable in the summer. Even the bear does not venture to cross the marshes when they are not frozen. Agricultural settlements may be found in this region on the banks only of the rivers, while some Ostiaks, Voguls, and Samoyedes find scanty means of existence in hunting and fishing. Farther north still begin the *tundras*, which extend along the Arctic seaboard as far as Kamchatka, and cover an aggregate area of some 450,000 sq. m.—more than twice the area of France. The climate of the tundras is really terrible; the average temperatures of December and January are 15 and 35 degrees below the zero of the Fahrenheit scale; the soil is frozen to a great depth, and only thaws on its surface during the short summer. The trees disappear, only a few species venturing to struggle against the cold by spreading as low bushes or by rising but a couple of inches above the ground. The want of drainage adds to the difficulties which vegetation has to cope with, and only a few flowering plants enliven occasional small patches of better protected and dryer soil. Of the plateau which fills vast tracts in East Siberia the upper terrace, 3000 to 4000 feet high, is quite unsuitable for agriculture, in consequence of its altitude, cold climate, and want of drainage; in fact, the whole of the Vitim plateau and its continuation towards Kamchatka is quite uninhabited. But its lower terrace, which is 2500 to 3000 feet above the sea and is separated from the upper by the Yablonovoi ridge, offers, especially in Trans-Baikal, great facilities for agriculture and cattle-breeding, and is peopled by both Buriats and Russians; while the smaller chains of mountains which intersect it are the seat of rich goldfields, and owing to their richness in copper, iron, and silver will certainly become some day an important centre for mining industry. The Great Khingan, which is continued farther north by the Stanovoi Khibet and is pierced by the Amur about Kumara, is the south-eastern border-ridge of the great plateau, and it also is fringed on its outer side by an alpine

belt of several chains of mountains running parallel to the border of the plateau. Owing to this character, the Stanovoi and the Great Khingan are a most important geographical boundary; properly speaking they separate Siberia from a region which is Manchurian in its physical features. As soon as the traveller has crossed this ridge (which hardly rises as a range of hills above the level of the plateau) and has descended a couple of thousand feet down a very steep slope leading to the basin of the Amur, he sees a complete change of scenery. The oak, the walnut-tree which he has not seen since he left the Urals, the vine, and a variety of bushes and trees belonging to the Manchurian and the Japanese floras suddenly make their appearance. When he has emerged from the alpine belt he finds again the same prairies which he has crossed on the Siberian slope of the plateau, and the climate of these prairies remains as continental and the winters almost as cold as in Siberia proper; but the general character of the flora and fauna is totally changed. In fact it is European no more; the species differ from their European congeners, new genera appear, and even the European species offer notable differences from the types familiar in Europe.

Another belt of high plains, 1500 to 2000 feet high, follows. These prairies, watered by the Zeya and its tributaries, and covered with a very fertile soil and excellent oak forests, are the richest part of the Amur territory. The picturesque Little Khingan or Bureya Mountains separate the prairies of the Middle Amur from the lowlands of its lower course. The whole of the latter is only now emerging from the Lacustrine period; immense lakes enclosed within quite flat shores intermingle with swamps; and when the autumn rains, due to the monsoons of the China Sea, swell the waters of the Amur and the Sungari, making of the former a stream several miles wide and covering all its low islands, the whole region becomes an immense swamp. Various small tribes of Manchurian origin (Golds, Mangoons, &c.) lead a half-aquatic existence on the banks of the Lower Amur and its tributaries, while the Russian settlements are reduced to a number of villages built on the river for maintaining communication along its banks. It is on the border of this region that the capital of the Amur territory, Khabarovsk, stands at the junction of the Amur with the Usuri. The rocky and inhospitable mountains of Sikhota-alin, intersected by equally low and swampy valleys, fill the remaining space towards the sea-coast—the mountains rising over the sea as a stone wall, almost entirely devoid of indentations. From Khabarovsk the valley of the Usuri leads southwards to Lake Khangka and to the fertile tracts on the frontier of Korea, which surround the Gulf of Peter the Great. In that gulf Russia has at Vladivostok a splendid harbour, reminding one by its general aspect of the Golden Horn of Constantinople. The fact that the port is frozen over during great part of the year detracts from its value as a naval station, but, by the loss of Port Arthur in the open China Sea (in the Russo-Japanese war, 1905), the peculiar value of Vladivostok (q. v.) to Russia was greatly enhanced. See the separate articles SAKHALIN, KAMCHATKA.

Communications.—The rivers of Siberia are of an immense importance for the life of the country. They all take their origin on the plateau, and, after having pierced the surrounding mountains, enter the plains, where they describe great curves and receive numbers of large tributaries before entering the sea. All of them have moreover this feature in common, that each of them is formed by the junction of a pair of great rivers: such are the Ob and the Irtysh, the Yenisei and the Tunguska, the

Lena and the Vitim, the Shilka and the Aigun which form the Amur. The three former enter the Arctic Ocean, and successful efforts have been made by explorers and traders, such as Wiggins, Webster, and Nansen (1913), to establish a regular communication between Europe and the mouths of the Siberian rivers, *via* the Kara Sea, which is free from ice for a few weeks every year. But for the interior communication the rivers are of still greater importance. It was by their means that the early Cossacks were able to overrun the country in so short a time. The Irtysh and the Ob are navigable as far as Sennopalatinsk in the Kirghiz Steppes, and Barnaul in the Altai Mountains; the Yenisei as far as Minusinsk, within 300 miles of the Mongolian frontier; the Lena as far as Verkholsensk, 200 miles N. of Irkutsk; and the Amur as far as Sryetensk in Trans-Baikal. Except for the railway connecting the Kama, a great tributary of the Volga, with the town Tiumen, more or less complete water communication can be maintained between Europe and Lake Baikal—there is a canal connecting the Ob and the Yenisei—but not across the plateau separating the lake from the Amur watershed. The rivers are free from ice only for a few months every year, while the lack of a direct outlet to the Caspian (and thence to the Mediterranean) is a decided disadvantage for Siberia. The Behring Strait was discovered in 1648 by the Cossack Dezhnev, but the scientific discovery of the passage between Asia and America belongs to Bering or Behring (1680-1741); Nordenskiöld was the first, in 1878-79, to accomplish the circumnavigation of Asia.

Overland communication is maintained by means of post-stations between all the chief towns—the great highway from Russia to the Pacific passing through Tiumen, Omsk, Tomsk, Krasnoyarsk, Irkutsk, Chita, Blagovestschensk, and Khabarovsk, the capitals of all the old southern provinces. Communication remains, however, difficult along the Shilka and the Amur, where long distances have to be traversed on horseback, especially when ice is drifting on the river before it is frozen, or when it is about to thaw. Two lines of railway enter Siberia from the west—the line from Perm to Tiumen, and the line from Ufa in the Bashkir Republic to Cheliabinsk, which joins at Samara the railway-net of European Russia. The trans-Siberian railway is a continuation of the latter, and was commenced in 1891. It establishes direct communication with the eastern seas, through Omsk (where it is joined by the line from Tiumen), Novo-Sibersk (where there is a branch to Sennopalatinsk in the Kirghiz Steppes; further east there is a small branch to Tomsk), Krasnoyarsk, Irkutsk, round Lake Baikal to Chita and Kaidalovo in Trans-Baikal, whence there are two lines to Vladivostok; one, by concession from China in 1896, through Manchuria, sending off a branch at Kharbin to Mukden and Port Arthur, and the other wholly in Siberia by Khabarovsk (finished in 1916). The complete line *via* Manchuria was opened for through traffic in 1904, the distance from Leningrad to Vladivostok by this route being 5672 miles, and was supposed to have cost some 87 millions sterling.

Climate.—It is a mistake to generalise about the climate of a huge territory such as Siberia from the sensational tales of the old penal settlements situated within or near the Arctic Circle (in Yenisei and Kamchatka), and though the winter is cold, the summer is warm. Beyond 60° N. the July average temperature varies from 60° to 40° F., and in moderate latitudes from 60° to 70° F., temperatures of 100° F. being occasionally recorded. The hot summer and a cloudless, bright sky favour vegetation, and melons are grown in the open air

on the steppes of Minusinsk and Irkutsk, and barley which has been sown in May about Yakutsk (62° 2' N. lat.) ripens by the end of August. The great wheat belt in central Siberia has the same latitudes as London and Paris. But the summer is short, as a rule, and cold weather sets in very rapidly. Night frosts are usual in September, and in November all rivers are frozen; even the Baikal becomes a highway for sledges in January. In November, even in South Siberia, the mercury of the thermometer is occasionally frozen, and in December and January it remains frozen for weeks. The spring begins in April or May, according to the latitude, and is very pleasant, though it still freezes hard at night; but in the second half of May, when all fruit-trees are in full blossom, there is a sudden return of cold which prevents apples and pears from being grown in Siberia. The average January temperature varies from 10° to -30° F., while in northern Yakutsk the climate gets rapidly worse. In the far north, indeed, the cold is really terrible, and Verkhoyansk, although its latitude is only 67° 34' N., is the cold pole of the eastern part of the northern hemisphere. Temperatures between -75° and -90° F. have actually been measured at Yakutsk and Verkhoyansk. Man certainly could not stand such low temperatures, were it not for the dryness of the atmosphere and the absence of wind during the great frosts, which render them more supportable than might be supposed. Not so with the snowstorms, which are frequent by the end of the winter, and are most dangerous to both man and cattle.

Population.—Since the revolution Siberia has formed part of Russia (q.v.) proper, itself the principal member of the Soviet Union; but different regions and republics, with varying scales of autonomy, have been created in Siberia. The following figures for areas and populations are those estimated for 1925:

Province.	Area in sq. miles.	Pop (estimate 1925).
Altai.....	49,044	1,642,317
Far-Eastern Region (comprising northern Sakhalin, Amur, Kamchatka, Trans-Baikal, and the Maritime Government).....	1,147,132	1,568,924
Irkutsk.....	326,090	665,084
Mongolo-Buryat Republic.....	20,965	432,371
Novo-Sibirsk.....	55,568	1,340,866
Omsk.....	96,544	1,649,958
Oyat Territory.....	36,506	83,500
Tomsk.....	158,625	1,125,173
Ural Region (including Perm in Europe, and Tobolsk in Asia).....	640,140	6,389,316
Yakutsk Republic.....	1,454,643	255,337
Yenisei.....	986,228	1,261,911
	4,978,085	16,414,757

The population is thus very unequally distributed. At the beginning of the 19th century the total population amounted to less than 1,000,000, but in 1897 it had attained to 5,727,090. The estimate of the Central Statistical Committee gave the figure as 10,377,900 in 1915. The increase of population since then is to a considerable extent accounted for by the inclusion in the Ural Region of the old government of Perm (mostly in the western slopes of the Urals), with some 4,000,000 inhabitants. The chief towns of Siberia are Omsk (143,000), Irkutsk (103,920), Vladivostok (99,000), Tomsk (89,887), Barnaul (81,504), Chita (79,000), Novo-Sibirsk (67,989), Blagovestschensk (63,000), Nikolsk-Ussuriski (62,000), Krasnoyarsk (59,000), and Khabarovsk (51,000), but on the whole the life is rural rather than urban. It has been estimated that about 92 per cent. of the population are Russians, 4½ per cent. Tatars, while the remainder belong to various stocks; some remnants of the indigenous population, nearly exterminated by the Mongols and later by the Russians, still linger in

the north of Yenisei and Tobolsk; various stems of Turkish origin, including the Yakuts, inhabit the slopes of the Altai and Sayan mountains; the Mongolian race is chiefly represented by the Buriats round Lake Baikal, and by the Tunguses in southern Yakutsk; there are some Manchurian, and in the far north-east the Hyperboreans, akin to the Eskimos. The condition of the aborigines is altogether precarious; their hunting and grazing grounds are constantly being invaded, and they themselves become an easy prey to traders, who plunge them into perpetual debt by means of loans of food, gunpowder, &c. The numbers of most of them are declining, which is to be regretted, because their children, when they have received education, often prove to be useful workers in various branches of science and art. The Tatars live a nomadic life, mostly in the provinces of Siberia west of Yenisei, and also in the steppes of Kirghiz, but have exchanged the pursuit of war for that of agriculture. The Russian colonisation has been made in five different ways—by Cossack and other military expeditions, by villages deported *en masse*, and by convicts and prisoners exiled by the tsarist government; and by traders and by peasants immigrating in large numbers of their own free-will. The convicts were sent to the north of Kamchatka, where there were mines, or to the north of Yenisei, but contributed little that was permanent to the civilising of the country; many died on the long pedestrian journey from Russia, or in the forests in attempts to escape from the settlements. The political exiles were given a certain amount of freedom, and, usually having a certain amount of education, were able to benefit the country to a considerable extent. During the last half of the 19th century over a million exiles were transported to Siberia. The Russian in Siberia is, on the whole, of an independent spirit, but almost devoid of poetical gifts, though successful, as a rule, in exact sciences. The chemist Mendeléeff, the historian Schapoff, and the zoologist Polyakoff were of Siberian extraction.

Agriculture, Industry.—Agriculture and cattle-breeding are the chief occupations. Wheat, and also corn, oats, barley, are grown fairly extensively in the south of the Ural Region, Tomsk, Irkutsk, and the Far-Eastern Region, while potatoes and beets are not so common. Sheep and cattle graze over the slopes of Eastern Siberia and North Manchuria, there is some horse-breeding, while the facilities afforded by the Siberian railway gave an extraordinary impetus to dairy-farming, especially in the west. Over the Kirghiz Steppes, cotton, tobacco, and fruit are grown, but irrigation is here badly required. Hunting continues to be profitable, notwithstanding the reckless extermination of wild animals and burning of forests which have been going on for three hundred years. Practically everywhere within the Arctic Circle furs can be obtained, the most important of which are ermine, sable, squirrel, and fox, and great annual fairs determine the price for the coming year. Fishing, especially salmon, herring, and sturgeon, is extensively carried on on Lake Baikal, the Amur, the Ob, and other rivers, and in the eastern seas. The timber wealth of Siberia is enormous, especially over the north and in the Far-Eastern Region, but of the 810,000,000 acres estimated to be covered with forest (cedar, fir, spruce, linden, birch, ash, oak, maple) about two-thirds are still practically unknown and unexplored. Industry is in its childhood, owing to the wants of the simplest technical knowledge. On the whole, the Russians in Siberia do not carry on the domestic industries so characteristic of middle Russia. Siberia is very rich in minerals. Coal is to be found more or less all over the country, but the best comes from the Urals, Irkutsk (north

of Lake Baikal), Amur, and Sakhalin. There are valuable gold mines in the Far-Eastern Region, and some silver, lead, and copper mines, which are also found in the Altai. Various minerals, including nearly the whole world's supply of platinum, come from the Urals. A considerable amount of water-power is available in central Siberia, but only a tithe of the natural wealth of the country has been exploited. Lack of capital, unfavourable climate, and uncertain political conditions have been serious drawbacks.

Religion.—A great variety of religions are met with in Siberia. The Russians belong chiefly to the Greek Orthodox faith, or rather to some of the nonconformist sects, the very making of Siberia being partly due to the emigration of dissenters persecuted by government in their mother-country, as well as to the runaway serfs, and at a later epoch, to the desire of avoiding military service. Most Turkish tribes profess the Mohammedan faith, the Buriats are Buddhists, and most of the indigenous tribes are Shamanists. Christianity is making but very slow and nominal progress.

Education stands at a very low level. A university was opened at Tomsk (1838), after much opposition on behalf of the government, but with only two faculties, medicine and physics. There is also a university at Irkutsk. In the chief towns there are gymnasia in which some education on classical lines is given, but primary and technical education is in great neglect. The technical societies of Irkutsk and Tomsk, the geographical societies at Omsk and at Irkutsk, and the natural science and anthropological museums of Irkutsk, Minusinsk, and Yeniseisk are worthy of mention.

History.—The earliest history of Siberia is still imperfectly known, and the numberless tumuli scattered over its surface only begin to be scientifically explored. See ART. Early inhabitants apparently of a stock different from the Ural-Altaians, are described by Radloff as Yeniseians. They were superseded in the 3d century A.D. by the Ugro-Samoyeds, whose bronze ornaments buried in the tumuli testify to a high pitch of artistic skill. They were subdued in the 11th century by Turkish invaders, who themselves were conquered, two centuries later, by the Mongols. The latter swept away the previous civilisation. The Russians, who vaguely knew Siberia from the 11th century through the Novgorodian merchants, began the conquest of the territory in 1580, when a band of Cossack robbers under Yermak subdued the Tatars on the Tobol River. New and new bands of Cossacks, traders, and hunters, supported by the Moscow government, and followed by dissenters flying from religious persecution and peasants escaping from serfdom, poured into Siberia during the next two centuries. The Cossacks took possession of the country, followed the courses of the Yenisei, Lena, and other rivers northward, and then reached the coasts of the Sea of Okhotsk within the first eighty years after Yermak's expedition. In 1643-50, under Poyarkov and Khabarov, they also took possession of the Amur, but were compelled by the Chinese to abandon their settlements and forts (1689). The estuary of the Amur was discovered in 1849, and a military post established at the mouth of the river in 1851. The left bank of the Amur and the right bank of the Usuri were annexed in 1853-57, chiefly through the exertions of Muraviev-Amurski; a chain of villages was built along both rivers, and the 'accomplished fact' was recognised by China in 1857 and 1860. The deportation of political and criminal prisoners, begun by the tsars in the middle of the 17th century, was officially organised during the 19th; and with the adoption in 1872 of Vladivostok as a naval base, and with the construction of the

Trans-Siberian railway (finished in 1904), Russia definitely adopted an aggressive policy in the Far East. In 1898 Port Arthur was leased from the Chinese to secure an ice-free port in the China Sea. After the Boxer rising large stretches of Manchuria were occupied, but the Treaty of Portsmouth (1905) after the Russo-Japanese War (see JAPAN, *History*) put an end meanwhile to Russian hopes and aspirations. There is little doubt, however, that in the decade before the Great War, Russia was concentrating more troops in Siberia than mere peaceful occupation would seem to warrant. By the Kiakhta Convention concluded in 1915 between Russia and China, Outer Mongolia was declared an autonomous state under Chinese suzerainty. Many disturbances resulted from the Russian revolution. Mongolian chiefs, Bolshevik leaders, 'white' generals and adventurers generally, collected armed bands and assumed an independence of their own. The situation was complicated by the landing in 1918 of Japanese troops, ostensibly to keep order, and of Americans; the latter left the country in 1920, but the former seized all the Russian littoral south of Korea, including northern Sakhalin, and only evacuated Siberia after the Washington Conference (1922).

For general description see books on Siberia by H. de Windt (1891), Stadling (1901), Turner (1906), Price (1912), Wright and Digby (1913), Channing (1923). See also Radloff, *Aus Sibirien*, and other works; Kennan, *Siberia and the Exile System* (4th ed. 1897), and other works; J. Y. Simpson, *Side-Lights on Siberia* (1898); Wright, *Asiatic Russia* (1903); Koulomzine, *Le Trans-Sibérien* (1904); Deutsch, *Sixteen Years in Siberia* (trans. 1905); Czaplicka, *Aboriginal Siberia* (1915); Pavolsky, *Russia in the Far East* (1921); works in German by Wiedenfeld (1916), Danckworff (1921), Schultz (1923); the Journals of Nordenskiöld (1881) and Nansen (1914); Ossendowski, *Man and Mystery in Asia* (1924).

Sibi, a pass, town, and district, in British Beluchistan, on the Afghan frontier. The town, which is 88 miles SE. of Quetta and has a station on the Sind and Pishin Valley Railway, is the residence of a British political agent. The inhabitants of the district, mostly Pathans and Beluchis, number about 119,000 (1921).

Sibyl, the name given in antiquity to certain inspired prophetesses, whether Apollo's mistresses or daughters, or merely his priestesses. The name is explained by Lactantius on authority of Varro as made up of the Doric *sos* = *theos* and *bylē* = *boulē*; Maas tries to connect it with the Eastern *Saba* or *Sabae*; Bang makes bold to connect it with the *Volva* and *Voluspā* of the Old Norse Sagas. Their number is differently given; some writers—Ælian and Pausanias, for example—mention only four, the Erythraean, the Samian, the Egyptian, and the Sardinian; Aristophanes and Plato use the word in the singular number only; but in general ten are reckoned, as by Varro—the Babylonian, the Libyan, the Delphian, the Cimmerian, the Erythraean, the Samian, the Cumæan, the Trojan or Hellespontine, the Phrygian, and the Tiburtine. Of these by far the most celebrated is the Cumæan, identified by Aristotle with the Erythraean, and personally known by the names of Herophile, Demo, Phemonoë, Deiphobe, Demophile, and Amalthæa. She figures prominently in the 6th book of Virgil's *Æneid*, as the conductor of the poet into the realm of the shades. Livy records the legend that she came from the east, appeared before King Tarquin, and offered him nine books for sale. The price demanded appeared so exorbitant that the king refused to purchase them. She then went away, destroyed three, and returning, asked as much for the remaining six as for the nine. This was again refused, whereupon she destroyed other three, and

The crops are guarded, and the losses of tenants from predatory animals, &c., certified, by mounted guards in the pay and uniform of the chief proprietors. Conditions of life are more primitive, and the spread of civilisation has been far slower (especially in the interior) than in many parts of Italy; but there is a very great difference between the north and east coasts and the rest of the island, which is more backward. But everywhere, except in the larger towns, and in such well-known resorts as Taormina, where adequate provision is made, facilities for the foreign traveller are lacking. As a whole, the Sicilian is manly and independent, good-humoured and obliging, prudent and steady in his habits. Under proper direction he will work hard and cheerfully, and his patience and resignation to his lot are truly Oriental: 'come Dio vuole' is but the 'kismet' spirit localised; but he can be treacherous and vindictive. The Mafia (q.v.) has only died with the new régime, until the advent of which the vendetta was preferred to more legal methods of punishment, so that criminal statistics still compared unfavourably with those for the rest of Italy. Emigration, especially to the United States, had assumed considerable proportions (141,880 in 1913) but has now been greatly reduced by their new immigration law. In religion the people are devout, and superstitious to a degree. Many of the popular festivals are of interest. Education is free and compulsory, but the law is not very strictly enforced, and illiteracy abounds. In 1895 there were 3500 elementary schools in the island, 13 normal schools, 67 'licei,' &c., 46 technical schools, besides government technical institutes, industrial schools, schools of mercantile marine, a military college at Palermo, a government conservatoire at Palermo, schools of agriculture and universities at Catania, Messina, and Palermo. The island is divided into seven provinces (see ITALY), and its chief towns are Palermo (pop. in 1921, 393,612; Messina (176,405); and Catania (252,448).

History.—The earliest inhabitants of Sicily of whom we know anything were the Sicani, belonging to the neolithic period. The Siculi, who followed them, do not appear to have been a distinct race, and probably both were branches of the same North-African stock. Professor Orsi, director of the museum at Syracuse, and of the administration of antiquities of the island, has divided the remains associated with the Siculi (fortified villages and cemeteries) into three periods, (a) down to 1500 B.C. (the eneolithic period); (b) 1500–1000 B.C. (the period of Aëgean importation); (c) 1000–500 B.C. (the period of increased Greek importation).

We hear of yet another early stock mainly in the north-western corner, the Elymtoi, whose towns of Segesta and Eryx showed a considerable progress in civilisation. The Phœnicians from an early period began to make settlements—Motya, Solous, and Panormus—on the north and north-west coasts, for the purposes of commerce; but the real civilisers of Sicily were the colonies of immigrant Greeks, both Dorian and Ionian, who founded a number of flourishing cities on the east and south coasts, such as Naxos (735 B.C.), Syracuse (734), Leontini and Catania (728), Megara Hyblæa (726), Gela (688), Himera (648), Zancle or Messina (date uncertain), Selinus (c. 628), Agrigentum (582).

These Greek settlers became known as Sikeliots, in distinction to the native Siculi, with whom, however, they gradually became assimilated. Their cities were long independent, and flourished first under oligarchical constitutions, then under the short-lived rule of a succession of more or less enlightened tyrants like Phalaris and Theron of Agrigentum, and Gelon, who in 485 transferred the seat of his power from Gela to Syracuse, thereafter the first city of the island. The inevitable struggle with Carthage soon began, and its first stage was closed for seventy years by the great victory of Himera (480), won over Hamilcar on the same day as Salamis, by the united power of Gelon and Theron. The long Peloponnesian war and the intrigues of the mother-cities in Greece drew Sicily into the current of Greek history, but the fatal Athenian expedition to Syracuse (415–413) under Nicias (q.v.) ended for ever the Athenian dream of a wider empire in the west. Next followed a Phœnician invasion under Hannibal, grandson of the Hamilcar who perished at Himera. His course of conquest was facilitated by internal jealousies, and he took in turn Selinus, Himera, and Agrigentum, leaving behind him nothing but smoking ruins. The strong fortress of Lilybæum was founded by the Phœnicians in 396, on the mainland, opposite the island town of Motya, taken and destroyed by Dionysius of Syracuse in the preceding year, whose vigorous reign (405–367) put a check to Carthaginian conquest. He fought Carthage in four wars, and carried his conquests into Southern Italy. After the tyranny of Dionysius and his son followed Dion and Timoleon, next the splendid but fatal reign of Agathocles (317–289). The Sicilian war of Pyrrhus of Epirus (278–276) was but the prelude to the long struggle between Rome and Carthage, the first stage of which was the war for Sicily. First Carthaginian Sicily in 241, then the whole island in 210 passed into a Roman province, on the death of Hieron, for fifty years a steadfast ally of Rome. The chief events in Sicily's Roman history were the two insurrections of slaves (135–132 and 102–99), the infamous pro-prætorship of Verres (73–70), its occupation by Sextus Pompeius (42), the conquest by the Vandal Genseric (440 A.D.), his cession of the island to Theodoric, and its recovery to the eastern empire by Belisarius (535). So it remained till 827, the date of the beginning of the Saracen occupation. Syracuse itself was taken in 877; the last stronghold, Rametta, fell in 965. For nearly a hundred years the Moslem rule was not seriously disturbed, but at length George Maniaces was sent by the eastern empire to win back the island (1038). His army included many Normans, who saw with eager eyes the goodness of the land. Town after town was taken—Messana, Syracuse, all save Panormus. The recall of Maniaces brought back a return wave of Saracen conquest, but at length, after much hard fighting, the Normans conquered the whole island; Panormus (Palermo) fell in 1071; Syracuse in 1085; Rametta (Noto), the last stronghold to hold out, in 1090. Robert Guiscard, son of Tancred of Hauteville, now took the title of Duke of Apulia and Calabria; his brother Roger, that of Count of Sicily. The Norman dominions were united under his son Roger, the great Count of Sicily, who took the title at Palermo in 1130 of 'King of Sicily and Italy.' He was followed by William the Bad (1154–66) and William the Good (1166–89), on whose death childless the Sicilians chose Tancred, an illegitimate grandson of King Roger. But Tancred died in 1194, whereupon the crown fell to the German Emperor Henry VI., who had married Constance, daughter of King Roger I. Henry forced the Sicilians to acknowledge him as king, and died in 1197, leaving the kingdom as his

son Frederick, afterwards the famous Emperor Frederick II. On his death in 1250 the succession fell to his son Conrad, next to his grandson Conradin, under whom Frederick's natural son Manfred governed Sicily. The latter declared himself king at Palermo in 1258 on an unfounded report of Conradin's death. But the popes pursued him with rancorous enmity, and on the nominal and shameless fiction of over-lordship offered his crown for money to Richard of Cornwall, brother of Henry III. of England, and next to Henry's younger son Edmund. At length Pope Urban IV., a Frenchman, opened up the most unworthy chapter of Sicilian history by granting it (1264) to Charles, Count of Anjou. Manfred fell fighting heroically against the invader just north of Benevento in 1266, and Anjou entered Naples in triumph. But Peter, king of Aragon, who had married Constance, the daughter of Manfred, laid formal claim to Sicily in her right. The government of the French proved intolerable to the Sicilians, and the massacre of the Sicilian Vespers (q.v.) opened up a long struggle, which ended with the crowning of Peter's son Frederick in 1296, and his being acknowledged at the peace of 1302 king of *Trinacria* for life. But he soon felt strong enough to resume his proper title of King of Sicily, and at his death in 1337 left the crown to his son Peter.

The Angevin House continued to reign in Naples, although they still maintained their nominal claim to Sicily—hence after the union the name Kingdom of the Two Sicilies. They upheld the Guelphic party; the Aragonese in Sicily, set up against the pope, were Ghibellines. Frederick's successors reigned on in Sicily, but in 1409 Mary, queen of Sicily, married Martin, son of Martin of Aragon, and through this the island was again united to the crown of Aragon. Queen Joanna II. of Naples, successor of Ladislas, was childless by both her marriages, and had first adopted as her successor Alfonso V., king of Aragon and Sicily, then revoked this disposition to adopt Louis III. of Anjou. The two parties went to war and divided all Italy: the Duke of Milan and Sforza on the Angevin side, the pope and the Florentines on Alfonso's. On the death of Louis the queen adopted his brother René of Anjou in his place. She died in 1435, and seven years later Alfonso succeeded in taking Naples, and died in 1458 king of Aragon, Naples, and Sicily. He left Aragon and Sicily, which he had inherited, to his legitimate son John II.; Naples, which he had won, to his bastard son Ferdinand I., whose cruelty made the chief citizens invite John of Calabria, son of René, to contest the crown. He was unsuccessful, but Charles VIII. of France revived the claim as the representative of the Angevin House, entered Italy in 1494, and made his progress in triumph to Naples, whence King Alfonso II. fled. Next year Alfonso's son Ferdinand II. returned to Naples to win back his kingdom. He died in 1496, and was succeeded by his uncle Frederick, who was betrayed by his kinsman Ferdinand of Aragon making an alliance with Louis XII. of France, and compelled to retire, giving up his rights to the French king. Next year (1502) the French and Spaniards quarrelled over their ill-gotten spoil, and the war was ended by the Spaniards utterly defeating the French at Mola near Gaeta in 1504.

Ferdinand the Catholic had thus again united Naples and Sicily to the Spanish monarchy. Both himself and his successor, the Emperor Charles V., had promised not to exact any new taxes from the kingdom of Naples without consent of nobles and people; but the viceroy of Philip IV. laid on grievous burdens, which at last led to insurrections both in Naples and Palermo, crushed mercilessly by Don

John, bastard son of Philip IV. In 1700 Charles II. of Spain died childless, whereupon Louis XIV. claimed the throne for his grandson Philip, Duke of Anjou, and the Archduke Charles of Austria for himself. The long war of the Spanish succession was closed by the peace of Utrecht (1713), which gave to Charles, now the Emperor Charles VI., Milan, Naples, and Sardinia, while the Duke of Savoy received Sicily with the title of king. Philip again plunged into Italian intrigues, and captured Sardinia by a treacherous attack. But the Quadruple Alliance (England, France, the United Provinces, and Charles of Austria) enforced the treaty. Victor Amadeus of Savoy had been on the side of Spain in hopes of gaining Lombardy, and the Powers compelled him in 1720 to give up his new kingdom of Sicily to Charles VI. in exchange for Sardinia. Don Carlos, son of the queen of Spain, after a series of intrigues, made an attack on Sicily, and at length in a readjustment of the map of Italy at the treaty of Vienna (1738) was acknowledged king of the Two Sicilies. As Charles III. was called to be king of Spain in 1759 he left Naples and Sicily to his younger son, Ferdinand IV., whose queen, Caroline, a sister of Marie Antoinette, naturally hated the French Revolution, and joined the English alliance. Bonaparte took Naples in 1798. King Ferdinand was turned out, allowed to return, but again turned out in 1806, when Bonaparte made his brother Joseph king. When Joseph was made king of Spain in 1808, Joachim Murat succeeded to his crown, Ferdinand being allowed to remain king of Sicily under British protection. By the treaty of Paris Italy was restored to her old masters. Victor Emmanuel received Sardinia with Genoa; the kingdom of Naples was restored to King Ferdinand IV. of Sicily, and he formally took the title of Ferdinand I. as king of the Two Sicilies. Ferdinand II. (1830-59) ruled Naples and Sicily with dreadful tyranny, bombarded Messina and Palermo, and flung the best citizens to rot in loathsome dungeons, especially after the unsuccessful revolution of 1848. Francis II. succeeded him; he had been brought up by the Jesuits, and under his rule the country ripened fast for revolution. At length Garibaldi sailed from Genoa with his thousand heroes, landed at Marsala, 11th May 1860, took Palermo, and at Milazzo defeated the king, who in abject terror promised all manner of reforms to Cavour and Victor Emmanuel. They did nothing but wait the issue, while Garibaldi crossed to Spatavento, drove back the king's troops, defeated them at Volturmo, and entered Naples in triumph on the 7th September. The people of Sicily and Naples joined themselves by a popular vote of more than a hundred to one to the Sardinian kingdom.

The palmiest age of letters in Sicily was the reign of the first Hiero (478-467), besung by Pindar; the next, that of the elder Dionysius, himself a poet and the friend of Plato. The lyric, the comedy, and the mime were practised by Stesichorus of Himera, Epicharmus, and Sophron of Syracuse; Empedocles of Agrigento was a famous philosopher, Archimedes of Syracuse the most celebrated of ancient mathematicians; but the rarest flower that grew out of Sicilian soil was the bucolic poem which once for all attained perfection in the idylls of Theocritus and Moschus of Syracuse, and in Bion, who, though a native of Smyrna, was a Syracusan in all his sympathies and in his grave.

The modern Sicilian dialect is of course closely allied to the Neapolitan, but offers grave difficulties both in vocabulary and grammar to the student acquainted only with Tuscan. It has furnished a rich literary material to the popular imagination for six hundred years down to our own day, and yielded a harvest of genuinely popular poetry not equalled elsewhere in the world. But not in their number alone are the Sicilian folk-songs pre-eminent, but in their intrinsic poetic excellence. The love-songs especially are tender, passionate, and

sincere, and many have a penetrating pathos that haunts the memory of a reader. They have been collected by S. Salomone-Marino, Dr Pitre (q.v.), and L. Vigo, whose *Raccolta amplissima di canti popolari Sicil.* (1870-74) alone contains 6000 songs, with besides a good bibliography of books in the Sicilian dialect. Dr Pitre's great *Biblioteca delle Tradizioni pop. Siciliane* (19 vols. 1870-90) is a vast encyclopædia of folk-songs and ballads, folk-tales, legends, proverbs, customs, games, jests, riddles, &c., with grammatical introductions and glossaries. Two other works that must be named are Laura Gonzenbach's *Sizilianische Märchen* (2 vols. Leip. 1877), and S. Salomone-Marino, *Storie popolari in Poesia Siciliana* (Bolog. 1877). For the Sicilian dialect, see the works by Wentrup (Halle, 1880) and C. Avolio (Moto, 1882); the Sicilian-Italian Dictionaries of G. Biundi (Pal. 1857) and V. Mortillaro (new ed. Pal. 1879).

There are histories of Sicily in antiquity by Holm (4 vols. Leip. 1870-98) and W. Watkiss Lloyd (1872); the Moslem period, by Amari (3 vols. Florence, 1854-72); the Norman period, by Bazancourt (2 vols. Paris, 1846) and Graf v. Schaack (2 vols. Stuttg. 1889); the Bourbon period, by Amari (Paris, 1849); the Piedmontese period, by Querner (Bern, 1879). See also the works on the history of Naples by Giannone and his continuator, Colletta; Seibert, Reuchlin, Orloff, Rustow, Romano-Manebrini, La Lumia, E. A. Freeman's unfinished *History of Sicily* (vols. i.-iv. 1891-94), and his short history ('Story of the Nations' series, 1892); G. M. Trevelyan, *Gariibaldi and the Thousand* (1909), *Guida d'Italia del Touring Club Italiano, Sicilia* (1919).

Sickert, WALTER, English painter of the Impressionist school, born at Munich in 1860, studied under Whistler, and has interested himself greatly in etching and engraving. His work is represented both in British and Continental galleries, and is fairly well known in Paris. He has painted landscapes, portraits, and *genre* pictures all with success. In 1924 he was elected A.R.A.

Sickingen, FRANZ VON, born on 2d March 1481 at the castle of Ebernburg near Kreuznach, fought in 1508 against the Venetians in the service of the Emperor Maximilian, but in peace led the life of a free-lance. He could bring 20,000 followers into the field, and during 1513-19 we find him warring against Worms, the magistrates of Metz, the Landgrave Philip of Hesse, and Württemberg. He twice levied ransoms of 20,000 and 30,000 gulden, and Charles V.'s election to the imperial crown was largely due to his influence. Reuchlin was protected by him at the capture of Stuttgart, and he formed a close friendship with Ulrich von Hutten (q.v.), who from 1520 was his constant guest, and won over his rude but lofty spirit to the cause of the Reformation. His fortresses, Landstuhl and Ebernburg, became the 'asylums of righteousness'; Bucer, Aquila, and Ecolampadius found refuge within their walls. In 1521 he assisted the emperor in his French campaign; in 1522, with the nobles of the Upper Rhine, he opened a Protestant war against the archbishop of Trier. That war miscarried; and put to the ban of the empire, and besieged in his castle of Landstuhl, on 2d May 1523 he received a musket-shot, of which six days later he died. In 1839 a stately monument to him and Hutten was erected at Ebernburg.

See works cited at HUTTEN, and monographs on Sickingen by Ulmann (Leip. 1872), Bremer (Strasb. 1885), and Hull (Ludwigsh. 1887).

Sickle. See REAPING.

Sicyon, an important city of ancient Greece, stood on a triangular plateau, between the rivers Asopus and Helisson, about 2 miles S. of the Corinthian Gulf and 7 NW. of Corinth. It was celebrated in antiquity for the unusual beauty of its bronze work, which exercised an important influence on the development of Greek art in general, and was the seat of a school of painting that included Pamphilus and Apelles, both natives of Sicyon. It was also the birthplace of Aratus

(q.v.), the general of the Achæan League, and of Lysippus, the sculptor. There exist at the present day a few remains of the ancient city, as well as of the more modern buildings erected by the Roman conquerors of Greece. These have been in part excavated by the American School of Classical Studies at Athens since 1887. Foundations of a great Doric temple were discovered in 1921.

Siddhartha. See BUDDHISM.

Siddons, SARAH, the greatest tragic actress England has produced, was the daughter of Roger Kemble, a respectable manager of a small travelling theatrical company, whose circuit was in the midland and western parts of England. Sarah, who was the eldest child, was born at Becon on 5th July 1755. From her earliest childhood she was a member of her father's company, and in a playbill dated 12th February 1767 her name appears as acting the character of the Princess Elizabeth in Havard's tragedy of *Charles the First*. When only seventeen she formed an attachment to Siddons, who was a member of her father's company, and, after considerable opposition from her parents, she was married to him in Coventry on 26th November 1773. Her husband and herself joined the Cheltenham Company, and while here she was recommended to Garrick by the Earl of Ailesbury. Garrick asked the Rev. Bate Dudley to report on her abilities, and is said to have also sent King, the actor, to see her. The result was an engagement at Drury Lane, where she made her first appearance on 29th December 1775 in the character of Portia. It has been said that the comparative failure which attended her first attempt to become a London actress was the result of pique on the part of Garrick; but there is no evidence whatever of this, and the fact seems to be simply that her powers were not matured sufficiently to enable her to produce an effect in the huge metropolitan theatre. At the end of the season she was not re-engaged, and for six years she played in the provinces, making her greatest successes in York and Bath; but her reputation grew so fast that in 1782 she was invited to return to Drury Lane. She accepted the offer, and made her reappearance on 10th October 1782 as Isabella, in Garrick's adaptation of Southerne's *Fatal Marriage*. Her success was immediate and permanent, and from this time to her retirement she was the unquestioned queen of the stage. In 1803 she followed the fortunes of her brother, John Philip Kemble, who had purchased a share in Covent Garden Theatre, and here she appeared on 27th September 1803 in her favourite character of Isabella. During the rest of her career she continued at Covent Garden, and at that theatre she took her formal farewell of the stage on 29th June 1812, when she played Lady Macbeth. She appeared occasionally after this time, but only for charitable objects or for special benefits. After her retirement from the stage Mrs Siddons gave occasional public readings from Shakespeare and Milton. She died on 8th June 1831, and was buried in Paddington Churchyard. As an actress Mrs Siddons stands unapproached, so far as can be judged from recorded criticism, in every line of tragedy—her pathos, her rage, her despair, her suffering, her grief, all being perfect in expression and convincing in naturalness. Endowed by nature with a gloriously expressive and beautiful face, a queenly figure, and a voice of richest power and flexibility, she worked assiduously to cultivate her mental and physical gifts until she reached a height of perfection which has probably never been surpassed by any player of any age or country. In comedy she was less successful. See Lives by Mrs Kennard (1886), and Mrs Parsons (1909).

Side-bones are enlargements situated on the coronet just above the quarters of a horse's hoof, resulting from the conversion into bone of the elastic lateral cartilages. They occur mostly on the forefeet in heavy draught horses with upright pasterns, causing some stiffness, but, except when they are of rapid growth, little lameness, though they are accounted amongst the defects that render a horse 'unsound.' They are treated at first by cold applied continually, until heat and tenderness are removed, when blistering or firing must be resorted to, and removal of pressure by shoeing with a 'bar shoe.'

Sidereal Clock, a clock so regulated as to indicate *sidereal time*; see DAY. The sidereal clock is a most important aid to the practical astronomer, and is one of the indispensable instruments of an observatory.

Siderite. See CHALYBITE.

Sideroxylon. See IRONWOOD.

Sidesaddle-flower is a name sometimes given to a plant of the genus *Sarracenia*. See INSECTIVOROUS PLANTS.

Sidgwick, ETHEL, novelist, was born at Rugby 20th December 1877, the niece of Archbishop Benson (q.v.). She studied music and literature at school in Oxford, and subsequently taught in England and France. Her novels, all showing a carefully cultivated literary style, are *A Promise* (1910), *Le Gentleman* (1911), *Herself* (1912), *Succession* (1913), *A Lady of Leisure* (1914), *Duke Jones* (1914), *The Accolade* (1915), *Hatchways* (1916), *Jamesie* (1917), *Madam, Restoration* (1923), *Laura* (1924). She has also written several plays for children.

Sidgwick, HENRY, writer on ethics, was born at Skipton, 31st May 1838, and educated at Rugby and Trinity College, Cambridge, being elected a Fellow in 1859. From 1875 he lectured as prelector of Moral and Political Philosophy, and in 1883 was elected Knightbridge Professor of Moral Philosophy. He first became widely known as an able writer on ethical subjects by his *Methods of Ethics* (1874), a critical examination of the principles underlying the various historic systems of moral philosophy, in which the points of resemblance between the opposing intuitional and utilitarian schools are particularly dwelt upon. The writer is on the whole fair to both sides, although his own sympathies lean to the utilitarian standpoint. The strongest feature of the book is its keen analytical power, which, however, drifts at times into the over-refinements of mere intellectual subtlety. Professor Sidgwick contributed numerous papers on ethical and economic subjects to *Mind*, the *Journal of Philology*, and other journals. He took a warm and active interest in the higher education of women, and was especially interested in the management of Newnham College at Cambridge. In 1886 he published as a separate book *Outlines of the History of Ethics*, the historical summary of the chief ethical systems and schools that he contributed to the ninth edition of the *Encyclopædia Britannica*; in 1883 *The Principles of Political Economy*, a work that maintains, with modifications, the essentials of J. S. Mill's method and results; in 1891 *The Elements of Politics*. Professor Sidgwick was president of the Psychological Research Society. He died 30th August 1900. *The Ethics of Green, Spencer, and Martineau* (1902), *Philosophy, its Scope and Relations* (1902), *European Polity* (1904), and his *Miscellaneous Essays* (1905) were afterwards published, and his life written by his widow and his brother.—His wife, whom he married in 1876, was ELEANOR MILDRED BALFOUR, born in 1845, a sister of A. J. Balfour (Lord

Balfour), and of F. M. and Gerald Balfour. She was treasurer and principal of Newnham College, honorary secretary of the Society for Psychical Research, and wrote on Mrs. Piper.

Sidi-bel-Abbès, a town of Algeria, 48 miles by rail S. of Oran; pop. 38,000 (two-thirds Europeans).

Sidlaw Hills. See FORFARSHIRE.

Sidmouth, on the south coast of Devonshire, 14 miles ESE. of Exeter, lies in a narrow valley at the mouth of the little Sid between the red sandstone cliffs of High Peak (513 feet) on the west, and Salcombe Hill (497) on the east. Its esplanade is protected by a sea wall (1838); its parish church (1259) was almost rebuilt in 1860. Sidmouth's prosperity as a port, which in Edward III.'s day sent two ships to the siege of Calais, passed away through the silting up of the harbour. The climate is mild, the rainfall the least in Devon, and the beach yields plenty of agates and chalcodones. Pop. (1921) 5669.

Sidmouth, HENRY ADDINGTON, VISCOUNT, prime-minister, was born in London, 30th May 1757, the son of Lord Chatham's physician, Dr Anthony Addington (1713-90). After twelve years at Cheam and Winchester schools, and four at Brasenose College, Oxford (1774-78), he studied law at Lincoln's Inn, married (1781), and was led by his friendship with Pitt to quit the bar for politics, in 1783 being elected M.P. for Devizes. He made an admirable Speaker from 1789 till 1801, when, upon Pitt's resignation on the Catholic relief question, he was invited by the king and urged by Pitt to form a ministry. That most third-rate administration, in which Addington was First Lord of the Treasury and Chancellor of the Exchequer, and whose one great event was the short-lived peace of Amiens (1802), came to an end in 1804. In the following January Addington was created Viscount Sidmouth; and thereafter he was thrice President of the Council, once Lord Privy-seal, and from 1812 to 1821 Home Secretary, as such being thoroughly unpopular for his coercive measures. He retired from the cabinet in 1824, and died 15th February 1844. He was a very sincere Tory. See his *Life and Correspondence* by his son-in-law, Dean Pellett (3 vols. 1847).

Sidney, or SYDNEY, ALGERNON, grand-nephew of the famous Sir Philip, was born probably at Penshurst, Kent, and in 1622, the second son of Robert, second Earl of Leicester (1595-1677). He received a careful education, and accompanied his father in 1632 on his embassy to Denmark, and in 1636 to France. In 1641-43 he commanded a troop of horse against the rebels in Ireland, of which country his father was (nominally) Lord-lieutenant. Then with his elder brother, Viscount Lisle, he returned to England, and, declaring for the parliament, was in March 1644 appointed to a troop in the Earl of Manchester's regiment. At Marston Moor he was severely wounded; in 1645 was appointed governor of Chichester, and returned by Cardiff to parliament; in 1646 attended his brother, now Lord-lieutenant, to Ireland as lieutenant-general of the horse and governor of Dublin; and in 1647, after receiving the thanks of the House of Commons for his services, was appointed governor of Dover. In 1649, though nominated one of the commissioners, he kept himself clear from any hand in the king's trial, which yet he justified on abstract grounds, speaking afterwards of the execution as 'the justest and bravest action that ever was done in England or anywhere else.' In principle a severe republican, he resented Cromwell's usurpation of power, and from the dissolution to the restoration of the Long Parliament (1653-59) lived in retirement at Penshurst. He then was nominated one

of the Council of State, and next was engaged for a twelvemonth on a political mission to Denmark and Sweden. After the Restoration he lived precariously on the Continent, flitting from place to place (Rome, Brussels, Augsburg, Montpellier, Paris, &c.); but in 1677 a pardon was procured for him from Charles II., and he returned to his native country. In 1679 he twice stood for parliament, but each time was jockeyed out of his seat in favour of the court candidate; and an attempt was made that same year to involve him in the sham Meal-tub Plot. The attempt miscarried; still, he deemed it prudent to retire for a while to France, where he bought a small property, and, to detach Louis XIV. from Charles, entered into negotiations with him through Barillon. That prior to this he had taken moneys from the French ambassador, either for himself or (more likely) for the republican cause, is admitted by Hallam and Macanlay, but disputed by A. C. Ewald, who contends that Barillon embezzled the thousand guineas that he set down to Sidney's account. Anyhow, to understand Sidney's relations with Louis, it must be borne in mind that he was hardly less hostile to William of Orange, as stadhouder, than to Charles himself, as king. Next year he was back in England, and, it is said on somewhat doubtful authority, assisted his friend, William Penn, to draw up the Pennsylvanian constitution, including the ballot, universal suffrage, the abolition of a property qualification, religious equality, prison reform, and the abolition of capital punishment except for murder and treason. In June 1683, when the Rye-house plot was announced, the chance was seized to get rid of men felt to be dangerous, and, along with Lords Russell, Essex, and Howard, Sidney was arrested and committed to the Tower. On 21st November he was tried for high-treason before the brutal Jeffreys, and, on no evidence but the traitor Lord Howard's and his own unpublished *Discourses concerning Government*, was found guilty and sentenced to die. He met his doom bravely on Tower Hill, 7th December, and was buried the next day at Penshurst. His attainder was reversed in 1689; his *Discourses* appeared first in 1698.

See Blencowe's *Sidney Papers* (1813), and the *Lives of Sidney* by S. W. Meadley (1813) and A. C. Ewald (2 vols. 1873), with other works cited at RUSSELL, SHAFESBURY, and CHARLES II.

Sidney, Sir Philip, has still about him, in spite of all that the effacing hands of time and change could do, a halo such as surrounds no other of his contemporaries. His unselfish chivalrous nature it is, bold at once and tender, his purity of life in the corrupt atmosphere of the Elizabethan court, above all, his heroic death, which make him still in a certain sense alive among us. Yet his was in fact an unadventurous life, wasted, not by his own fault, despite of strenuous endeavour; whilst by a kind of pathetic irony the fame which preserves his gracious memory has perversely failed to do justice to that true and passionate verse which in his own day placed him at the head of our poetry next in succession to Chaucer. Sidney, born 30th November 1554, at Penshurst, Kent, and named after Philip II., was son to Sir Henry, a man of high birth and noble character, married to Mary Dudley, daughter to the Duke of Northumberland (executed for treason 1553), and sister to that base and hypocritical Lord Leicester, of all Queen Elizabeth's favourites the most ill-chosen and baleful. Philip was sent first for education to Shrewsbury School (1564), thence (c. 1568) to Christ Church, Oxford—possibly to Cambridge also. He studied hard, as his writings show, and made his two best friends, Greville, afterwards Lord Brooke, and Dyer; men likeminded with himself in a certain seriousness

and manliness of character, such as was naturally formed by the atmosphere of that age—troubled, yet full of hope and energy.

From 1572 to 1575 Sidney travelled in France, Germany, and Italy, completing his education after the fashion of those days, returning well versed in the best Italian literature, but unspoiled by foreign temptations. He was not a man to verify the proverb of that day, 'A devil incarnate is the Englishman Italianate.' Few men or none were then more powerful in England than his uncle Leicester, and Sidney at once began to make his career at court, then the only portal to public life. His character was now fully formed as the model of a finished English gentleman; in Spenser's fine phrase he was the 'President of noblesse and of chivalry.' Yet as a statesman Sidney practically failed. At first a favourite of the ever-fickle queen, he accompanied her progresses; he was sent ambassador (1577) to Rudolph II., and then to William, Prince of Orange. There is a vague story that he was thought of as candidate for the uneasy Polish throne; he certainly longed to join Prince Casimir, then in arms in the Netherlands. But he was not yet (1578) fated to visit Zutphen.

Sidney's court position now became trying. Elizabeth displayed her too frequent ingratitude toward his father for his exertions as Lord Deputy in Ireland, and Philip wrote in his defence with much ability and courage. And in similar style he addressed the queen against her desired match with the miserable Duke of Anjou. Elizabeth hence frowned upon him; whilst, meanwhile, Leicester's own marriage with Lady Essex had removed him from court. Sidney also retired (1580) to his admirable sister Mary, now Lady Pembroke, at Wilton, where most, probably, of his *Arcadia* was written.

Of Sidney's life in 1581-82 we know little. He returned to court, like Spenser,

To lose good days, that might be better spent;
To waste long nights in pensive discontent.

tortured also with the hopeless love, which we shall notice further on. In 1583 he was knighted; he received a paper-grant of 3,000,000 acres in 'certain parts of America not yet discovered'; and married Frances, daughter to Sir F. Walsingham. But although he may thus have thought to strengthen his position, Sidney was doomed to yet another disappointment. The arrangement which he had settled (1585) to accompany Drake on one of his buccaneer expeditions to America was defeated by Elizabeth's weakness or caprice and Drake's jealous treachery. Indeed, when seen not through the haze of tradition, the distorting mists of partisanship, but in natural light, the popular heroes of that day often drop their halo. But this subject belongs to that unwritten section of our annals, the true history of the Elizabethan age.

It was poor amends that Sidney was ordered to accompany Leicester, chosen for her general by the queen's infatuation, to carry her half-hearted and untrustworthy support to the Netherlanders in their agony and struggle against Spain. Upon the miseries of Sidney's position in his partial charge of that thrice disgraceful expedition we need not dwell. For nearly a year he was detained in idleness; then, after one small brilliant exploit, he received a wound upon 22d September 1586 in a chivalrous conflict, rash as the English charge at Balaclava, under the walls of Zutphen. He died on the 17th October, not so much of his wound, it would appear, as of the crude surgery of his day; and was mourned by England with a unanimity and a depth of feeling never surpassed—perhaps never equalled.

By 1579 Sidney, who perhaps through Gabriel

Harvey, had become acquainted with Edmund Spenser, a year or more his senior, is thought to have formed with him and some others a little literary society, which aimed at rejecting rhyme and writing English poetry in classical metres. Of that folly Sidney soon repented; but a few letters between Spenser and Harvey upon the subject, happily preserved, are noteworthy as the sole contemporary notice of Sidney's own work in literature, which we may place between 1578 and 1582. Widely celebrated as that work was during Sidney's lifetime, yet nothing of it was published till after his death. He 'purposed no monuments of books. . . . His end was not writing, even while he wrote,' said his friend Greville. Like his immediate predecessors Wyatt, Surrey, Sackville, he was statesman or courtier first, author only in leisure hours. His writings must have been partially made known by MS. circulation; yet we may suspect that Sidney's own brilliant character, his connections, which placed him in the very foremost rank of high life, his generous patronage of men of letters, with the report of those to whom his writings were communicated, united to give him his pre-eminent contemporary reputation. This was, however, amply supported when the *Arcadia* (written for his sister, Lady Pembroke, probably 1578-80, but never finished) appeared, imperfectly in 1590, completely in 1598. This book, for perhaps about a century, retained a vast popularity, though now almost unread, and indeed unreadable. It is a pastoral romance, founded primarily upon the *Arcadia* (1504) of the Neapolitan Sannazzaro, being, like that, an intricate love-story, intermixed with poems and written in melodious but elaborate prose, and not free from the artificial 'conceits,' the Euphuism, familiar in Europe to that age. But the Portuguese Montemayor's *Diana* (1542), the old Greek romance *Theagenes and Chariclea*, with, doubtless, other traditional legends, had also their share in Sidney's story; whilst its many incidents, disguises, and intricacies supplied material for later writers. But the main value of the book perhaps lay in this, that here Englishmen found their earliest model for sweet, continuous, rhythmical prose—for the prose of art. Before the *Arcadia* we have fine single passages; no such consistent whole. The verse portions are rarely happy; they must have been among Sidney's earliest attempts; but in truth his genius required that high heat of personal passion which inspires *Astrophel* to fuse his ore into gold; although that ore (to pursue the figure) is always weighty with Sidney's seriousness, his elevated thought, his chivalry of nature. As of exceptional merit may be noticed the dialogue between Nico and Dorus, and an Epithalamium of stately dignity, which may have been suggestive to Spenser. In *Arcadia* Sidney tried numerous metres, English, Italian, classical; the latter, inevitably, with small success.

To about 1580 may be assigned Sidney's *Apology for Poetry* (afterwards named *Defence of Poesy*), in reply to an abusive Puritan pamphlet, and to a general disesteem then felt in England for that art; published 1591. In this tract, written in clear, manly English, and still well worthy of readers, Sidney defines poetry, after Aristotle, as Ideal Imitation, and for her claims her ancient place as the highest mode of literature, teaching mankind the most important truths through the medium of that pleasure which is the formal end of all fine art. In mediæval fashion, many authorities are quoted, and Sidney displays his wide range of reading. Lastly, he criticises severely and justly the crowd of contemporary versifiers—not peculiar to that age!—to whose want of power, bad taste, and trivial style he partly ascribes the then existing low estimate of poetry. And here he names the best English

poets known to him: Chaucer, Sackville, Surrey, and Spenser's just (anonymously) published *Calender*. 'Besides these, I do not remember to have seen but few (to speak boldly) printed, that have poetical sinews in them.' English drama, it will be remembered, was then in its cradle.

Sidney, like Shelley, was so great a poet that he had just right to come forward in defence of poetry. But for himself it was love, not instruction, that moved him:

Come, let me write: And to what end? To ease
A burthen'd heart;

and again, to his Love,

Only in you my song begins and endeth.

For the origin of *Astrophel and Stella* (published 1591), however, we must go back to an episode in Sidney's life. In 1575, aged twenty, he met Penelope Devereux, daughter to Lord Essex, then a child of twelve. Some intimacy followed, and Essex, on his deathbed (1576), expressed a hope that the two might in due time marry. In Sidney's nature, however, was some want of youthfulness; his heart did not respond, and it was only in 1581, when Penelope was engaged and wedded (apparently without love on her part) to Lord Rich, that Sidney awoke too late to find *Quid sit Amor*—to find also that she might have loved him. It is hence a sad drama, a miniature tragedy in lyrics, that is revealed in this long series; as Nash, the editor, said, 'The argument, cruel chastity; the prologue hope, the epilogue despair.'

These 108 sonnets and 11 songs (to which a few separately published in 1598 may be added), after, or rather with, Shakespeare's sonnets, have long seemed to us to offer the most complete and powerful picture, in this form, of passionate love, in our language.

Considering the charm that Sidney's name still exerts, the close relation of his poetry to the romance of his life, and the high place in our literature merited by its great qualities, that as poet he should have met hitherto so imperfect a recognition is little to the credit of popular taste. That high place has been amply vindicated in the admirable essay by the most exquisite of poetical critics, Charles Lamb. But that Sidney's fame falls far below his deserts is due in part to that inequality of his workmanship which he shares with other supreme writers of sonnet-sequences; with Petrarch, Shakespeare, and Wordsworth. Nor did life allow him to acquire then finished art. 'His end was not writing, even while he wrote.' Fanciful conceits, obscurity from the depth and wealth of thought, are not unfrequent; at times the style is prosaic, bare, unmelodious. But over-fancifulness was the defect of that age: obscurity is common to his great rivals, when moving in the sonnet's narrow bounds.

Sidney's Poetry and *Apology* were carefully edited, the first by the Rev. A. B. Grosart (3 vols. 1877), the second by Arber (1868) and Shuckburgh (1891); Professor Feuilleat has edited the *Complete Works* (4 vols. 1912-26), including the original version of the *Arcadia*, discovered in 1907. Dr H. Oskar Sommer published in 1891 a photographic fac-simile of the original quarto edition of *Arcadia* of 1590. Fulke Greville's *Life* (1652) was re-edited by Sir Egerton Brydges (2 vols. 1816). See also the *Life* by M. W. Wallace (1915); the *Sidney Papers*, edited by Arthur Collins (1746); the *Correspondence of Sir Philip Sidney with Hubert Langnet*, edited by Stewart A. Pears (1845); *The Sydneys of Penshurst*, by Philip Sidney (1901); and the article ZUTPHEN.

Sidon (Heb. *Sidon*), anciently a city of Phœnicia, situated on the east coast of the Mediterranean, half-way between Tyre and Beirut. It soon rose, both by its exceptional position and the enterprising character of its inhabitants, to a

leading position among the cities of Phœnicia (q.v.), so that the whole country is sometimes designated by the name of Sidon, 'the Great,' 'the Metropolis.' The extensive commerce of Sidon is well known from ancient authorities. It was always better known to the Greeks than its rival Tyre; and, when the latter declined during the Persian age, it reached its highest prosperity. An unsuccessful revolt against Artaxerxes Ochus ended in its temporary ruin (351 B.C.). Speedily rebuilt and repopled, it opened its gates to Alexander the Great (333 B.C.), and from that time forth it fell successively into the hands of Syrian, Greek, and Roman rulers. Through the middle ages little is heard of it, except that it was taken by the Crusaders. The present town of Saida has 12,000 inhabitants, of whom 8500 are Mohammedans. In the neighbourhood are numerous rock-cut burial-places of the ancient Phœnicians, in which have been found the sarcophagus of Eshmunazar, king of Sidon, and others. The town was stormed by the allies under Napier in 1840.

Sidonius Apollinaris, a 5th-century churchman and author, descended from a noble Gaulish family, held high civil offices at Rome and in 472 became bishop of Clermont. Born about 430, he died in 483. His letters (nine books) are modelled on Pliny and other classics; his poems (twenty-four books) comprise panegyrics on three emperors and two bombastic epithalamiums.

See the Abbé Chaix, *Saint Sidoine Apollinaire et son Siècle* (2 vols. Clermont, 1867-68); works by Chatelain (Paris, 1875) and Kaufmann (Göttingen, 1864); Hodgkin's *Italy and her Invaders* (vol. II. book III.; 1880). There are editions by Baret (Paris, 1879) and Lutjohann (Berlin, 1888); a translation of the Letters by O. M. Dalton (1915).

Siebenbürgen ('Seven Castles'), the German name of the former principality of Transylvania.

Siebengebirge, or 'Seven Mountains,' in Rheinland, on the right bank of the Rhine, about 20 miles above Cologne. The highest is the Ölberg (1522 feet); but the most famous is the Drachenfels (q.v.). The crags are crowned with ruins of baronial castles of the 12th century. Trachyte is quarried amongst these hills; from them the stone was obtained for the greater part of Cologne Cathedral.

Siebold, PHILIP FRANZ VON, physician and botanist, was born at Würzburg, 15th February 1796, became sanitary officer to the Dutch in Batavia, and, accompanying the Dutch embassy to Japan, did much to make Japan known to the western world. He spent 1826-30 in Japan, wrote on the country, its flora, and language, and died 18th October 1866.—His brother KARL THEODOR ERNST VON SIEBOLD, anatomist, was born 16th February 1804, and became famous as professor at Munich (1853), where he died, 7th April 1885. He wrote works on the Invertebrata (Eng. trans. 1857), on tapeworms, on parthenogenesis, on salamanders, and on the fresh-water fishes of central Europe. See Life by A. von Siebold (1896).

Siedlce, a town of Poland, 57 miles by rail E. by S. of Warsaw, in the voivodeship of Lublin; pop. 30,800.

Siege (Fr., 'a seat,' 'a sitting down'). When the assault of a fortified place would be too hazardous and costly and its reduction by blockade too slow, recourse is had to the *regular siege* or *systematic attack*. Until the advent of the high-explosive shell of great calibre in the 20th century, the art of besieging was stereotyped with all the rigidity the word stereotype implies. In the earlier days artillery was rarely powerful enough to destroy sufficiently a fortress, unless it were a small one,

for the assailant to be able to count upon capitulation from sheer demolition; so he had to contrive means for crossing the open ground with the least loss. Great engineers like Vauban, builders of fortresses, set their minds also to the attack of fortresses, and with such success that they could 'guarantee' to capture a given fortress in a given number of days. The plan was to approach below the surface of the ground, by trenches while still at a distance, by sapping when close up, and by mining when the enemy was proving obstinate. (A trench is begun by men standing on ground level, a sap by men pushing forward from the floor of an existing trench.) The first thing after the enemy had been driven into his works was to establish, on the front chosen for active attack, a long trench facing the place from which good small-arm fire could deal with sorties by the foe. This trench, the *first parallel*, being completed and the siege batteries installed, zigzag digging carried forward the attack until a second and a third parallel brought the besiegers close to the hostile works. Sapping and mining would then begin, and the ideal of the engineers was that, certain sections of trench or sap being completed daily and nightly, the attack should reach the fortress ditch by a certain date, close to where the guns had meanwhile been effecting breaches of the main revetments and ramparts. It was remarkable how often the time-table would work out to date, if the besieged failed to make any successful sorties. On the other hand, if the place were not completely invested, as at Sebastopol (1854-55) and at Delhi (1857), the attack was liable to interruption by threats on its flanks.

Interference from a hostile field army has also to be guarded against. This used to be done of old by a *line of contravallation* guarding the besiegers on the outside, *circumvallation* being the term applied to the siege-works proper. But, when armies became more mobile, it was found better to send out a *covering army* to meet the enemy's field troops at a distance. A place, properly invested and besieged, and not succoured from outside has hardly ever survived. The distinction between siege proper and a mere blockade or investment must be kept in mind. In 1870 Strasbourg, with an indifferent garrison of 20,000, was besieged actively by the Germans with 60,000 men, and won in less than two months. Metz, with 170,000 soldiers in it, was blockaded by about 200,000 Germans, and was starved out in about the same time. Paris, blockaded and partially bombarded, was also starved out. In 1912 the Turks lost Adrianople by siege, which was now taking the form of destruction by shells more than close threat of infantry. In the Great War, besieging, except on two occasions at Przemyśl in Galicia, took the form of complete pulverisation by high-explosive shells. The systematic advance of Vauban's day has given place to sheer demolition; the sapper has made way for the gunner.

The siege outfits of the Great War were incomparably more powerful than at any previous time. Guns and howitzers that equalled in power all but the very heaviest ships' artillery were brought into the field by tractors or on rails, and fired shells which, by power of explosion and accuracy of flight, rendered nugatory all existing permanent defences. It came about, in fact, that a fortress, left to anything like its normal garrison, as Liège and Namur and Maubeuge were, could not hope to survive more than a few days. The *siege parks* or main depôts for the besieger's artillery and engineers have increased in proportion to the size of armies; but the increasing facility of traction by road and rail has made it possible to keep these vast organisations out of reach of the fire of the besieged.

Most of the so-called sieges of the Great War were not sieges at all; they were merely prolonged pitched battles in which certain forts took a part. The 'siege' of Verdun by the Germans (1916) was a notable case in point. The *garrison* of the whole place was before the war intended to be less than 100,000 men. Long before the unsuccessful German attack was over, there was a field army of 400,000 French fighting among and in front of the original permanent works.

Mining used to be a marked feature of obstinate sieges. In the Great War, if the word siege be confined in application to the attack of permanent works, there was no scope for mining in sieges. But if we apply 'siege' to the systematic approach and capture of strong field works, most of the war in France and Belgium was a siege, and a large amount of mining was done, met by countermining on the part of the adversary. In older days the first mining in a siege was usually undertaken by the besieger for the purpose of blowing in the counterscarp of the fort's main ditch. See also FORTIFICATION and MINES.

Among great sieges in the world's history may be mentioned those of Troy, Tyre (572, 332 B.C.), Syracuse (396 B.C.), Saguntum (219 B.C.), Jerusalem (70 A.D.), Acre (1191, &c.), Calais (1347), Orleans (1428), Constantinople (1453), Haarlem (1572-73), Leyden (1574), Breda (1625), Rochelle (1628), Magdeburg (1631), Breisach (1638), Taunton (1644-45), Londonderry (1689), Gibraltar (1731, 1779, 1782-83), Prague (1741-44), Quebec (1759-60), Seringapatam (1799), Genoa (1800), Saragossa (1808-9), Ciudad Rodrigo (1810, 1812), New Orleans (1814), Antwerp (1832), Rome (1849), Sebastopol (1854-55), Kars (1855), Lucknow (1857), Delhi (1857), Gaeta (1860-61), Vicksburg (1863), Charleston (1863-64), Richmond (1864-65), Metz (1870), Strasburg (1870), Belfort (1870-71), Paris (1870-71), Plevna (1877), Khartum (1884), Ladysmith and Mafeking (1899-1900), Port Arthur (1904), Adrianople (1912), Maubeuge (1914), Przemyśl (1915).

In what is called the 'state of siege' civil law is suspended or made subordinate to military law. A fortress, city, or district is thus put under martial law—i.e. under the authority of the military power—either on account of the presence of an enemy, as at a siege, or because of the failure of the civil power, as in the case of domestic insurrection, or of a conquered district in military occupation. The *minor state of siege*, a modification of the more severe rule, usually suffices for domestic troubles. No such provision is made by the laws of the British Empire or of the United States, though very similar powers are exercised when martial law is proclaimed. For this no rules are made—the possibility of civil war is not presupposed; but should the civil power become inoperative it is the duty of the supreme authority to maintain order by any means (usually of course an armed force) that are available, afterwards coming to parliament for an act of indemnity to justify conduct in itself contrary to law. Perhaps an approach to the continental *minor state of siege* may be found in the restricted power to try offenders in Ireland by military tribunals created by act of parliament in 1799, 1803, and 1833.

Siegen, a town of Prussia, in Westphalia, stands on the Sieg, 47 miles E. of Cologne, manufactures leather, paper, linen, soap, iron, copper, lead, zinc, &c., having many mines in the vicinity. Siegen was the birthplace of Rubens. Pop. 31,000.

Siegfried, or SIGFRID. See NIBELUNGENLIED.

Siemens, WERNER VON, engineer and electrician, was born 13th December 1816 at Lenthe in Hanover. In 1834 he entered the Prussian artillery, and in 1844 was put in charge of the

artillery workshops at Berlin. He early showed scientific tastes, and in 1841 took out his first patent for galvanic silver and gold plating. He was of peculiar service in developing the telegraphic system in Prussia, and discovered in this connection the valuable insulating property of gutta-percha for underground and submarine cables. In 1849 he left the army, and shortly after the service of the state altogether, and devoted his energies to the construction of telegraphic and electrical apparatus of all kinds. The well-known firm of Siemens and Halske was established in 1847 in Berlin; and subsequently branches were formed elsewhere. Besides devising numerous useful forms of galvanometers and other electrical instruments of precision, Werner Siemens was one of the discoverers of the principle of the self-acting dynamo (see DYNAMO-ELECTRIC MACHINES). He also made valuable determinations of the electrical resistance of different substances, the resistance of a column of mercury, one metre long and one square millimetre in cross section at 0°C., being known as the Siemens Unit. His numerous scientific and technical papers, written for the various journals, were republished in collected form in 1881. In 1886 he gave 500,000 marks for the founding of an imperial institute of technology and physics; and in 1888 he was ennobled. He died at Berlin, 6th December 1892. See his *Personal Recollections* (translated, 1893) and his *Scientific Papers* (2 vols. 1892-95).

Siemens, SIR WILLIAM (KARL WILHELM), the younger brother of Werner Siemens, was born at Lenthe in Hanover, April 4, 1823. He was educated at the trade school at Magdeburg, and spent a year in study at Göttingen University, where he worked hard at science. In 1843 he visited England, and was successful in introducing a process for electro-gilding invented by his brother Werner and himself. In 1844 he again came to England and patented his differential governor. Thenceforward he made England his home, and became a naturalised British subject in 1859. In 1862 he was elected a Fellow of the Royal Society, and was presented with the Royal Albert Medal (1874) and with the Bessemer Medal (1875) in recognition of his researches and inventions in heat and metallurgy. He filled the president's chair in the three principal engineering and telegraphic societies of Great Britain, and in 1882 was president of the British Association. He was knighted in April 1883, and died on November 19 of the same year. As manager in England of the firm of Siemens Brothers, Sir William Siemens was actively engaged in the construction of overland and submarine telegraphs. The steamship *Faraday* was specially designed by him for cable-laying. In addition to his labours in connection with electric lighting, Sir William Siemens also successfully applied, in the construction of the Portrush Electric Tramway (opened 1883), electricity to the production of locomotion. In his regenerative furnace (1856) he utilised in an ingenious way the heat, which would otherwise have escaped with the products of combustion. The process was subsequently applied in many industrial processes, but notably by Siemens himself in the manufacture of steel (see IRON AND STEEL). Of his miscellaneous inventions and researches, the following are particularly worthy of mention: a water-meter; a thermometer or pyrometer, which measures by the change produced in the electric conductivity of metals; the bathometer, for measuring ocean depths by variations in the attraction exerted on a delicately suspended body; and the hastening of vegetable growth by use of the electric light.

See his *Life* (1889) by Pole and his *Scientific Works* (1889).

Siena, a Tuscan city 60 miles by rail S. of Florence; it is still surrounded by walls, and, owing to its situation on three hills and the number of buildings in the Gothic style which it still retains, is one of the most picturesque towns in Italy, with a predominantly mediæval aspect. The chief architectural glory of Siena is her cathedral, one of the finest examples of Gothic work in Italy. It was begun early in the 13th century; in 1339 it was intended to build a vastly larger church, of which the existing cathedral should have been only one transept. But after

Cathedral at Siena.

the plague of 1348 the idea was abandoned, and only ruined walls indicate the ambitious design. The magnificent west front with its three bays was not finished until 1380; it is partly pointed, partly round-arched, and is enriched with red, white, and black marbles, gilding, and many sculptures. A lofty square campanile stands on the south side. The art treasures of the interior embrace the wonderful octagonal pulpit by Niccolò Pisano (1268), similar to the one at Pisa; the marble mosaic floor of the cathedral, from designs by Buoninsegna and Beccafumi; the series of frescoes commemorative of the life of Pope Pius II., by Pinturicchio, in the Piccolomini Library, where also are preserved several choir-books splendidly illuminated by Siennese artists; the celebrated font, with bas-reliefs by Donatello, Della Quercia, and other sculptors, in the church of San Giovanni, situated beneath the cathedral. The churches of Sant'Agostino, the Servites, San Domenico, and some others contain pictures by Sodoma, Matteo di Giovanni, and other Siennese artists. The greatly venerated Church of St Catharine (q.v., a native of this city) stands on the site of her former dwelling-house; and not far away is the fountain of Fontebranda, celebrated by Dante. The municipal palace, in the picturesque market-place (Piazza del Campo), a magnificent edifice of brick in the Pointed Gothic style, begun in 1288 and finished in 1309, is adorned on the exterior by a lofty tower (1348), and contains numerous paintings by Siennese artists and the reliefs of the Fonte Gaia, the masterpiece of Jacopo della Quercia (1409-19)

which stood in the piazza, where it has been replaced by a modern copy. There are several noble palaces, as the Piccolomini, Tolomei, Monte de' Paschi, Loggia del Papa, some dating from the 13th century, and some now put to various public uses. The more noteworthy of the public institutions are the university, with faculties of medicine and law, founded in 1203; the state archives and the town library; and an Institute of Fine Arts (1816), sheltering in its gallery many fine pictures by masters of the Siennese school, the principal of whom are Buoninsegna, the brothers Lorenzetti, Simone di Martino, Matteo di Giovanni, Peruzzi, Sodoma (Bazzi), and Beccafumi. The city has also given birth to a host of other illustrious men, as Æneas Piccolomini (Pope Pius II.), Gigli (a scholar and a humorist), Bernardino Ochino, the two Socini (founders of Socinianism), and the architects Agnolo, Agostino, and Della Quercia. Every July (2d) and August (16th) celebrated horse-races (the Palio, so called from the banner given to the winning *contrada*, or ward of the city) are held in the market place, being the survival of still more widely celebrated popular festivals of the middle ages. The inhabitants weave silk, manufacture cloth and hats, and carry on an active trade in wine and olive-oil. Siena is the seat of an archbishop. Pop. of commune (1921) 43,879.

Siena was made a Roman colony by Augustus under the name of *Senia Julia*. After the empire was broken up the city was under the rule of a *gastaldo* under the Lombards, and of a count in the Carolingian period, whose authority gave way to that of the bishop. Later on it formed itself into a free republic, governed by consuls, and grew so much in power and prosperity that it became the head of the Ghibelline towns in Central Italy. During this period (the 12th and 13th centuries) it had a dangerous rival in Florence, but inflicted a crushing defeat upon the Florentine militia at Montapertro in 1260. A century later, however, when hard pressed by Florence, the Siennese put themselves (1399) under the protection of the Duke of Milan. Nevertheless hostilities were frequently renewed with their powerful rival during the 15th century. Between 1487 and 1512 the virtual ruler of Siena was Pandolfo Petrucci, called the Magnificent, who aimed at founding a dynasty in his native city similar to that of the Medici in Florence; but his descendants were not the men to realise his ambitions, and in 1524 the people, to escape from the dominion of the Petrucci, put themselves under the suzerainty of the Emperor Charles V. Yet soon afterwards the city revolted and called in the French to its aid; but it and its ally were defeated and Siena itself besieged (1555) and taken. The emperor then gave it to Cosimo de' Medici (1557), who annexed it to Florence, and subsequently incorporated it in Tuscany (q.v.).

See W. Heywood, *Our Lady of the Palio* (1899) and other works; L. Douglas, *History of Siena* (1902); E. G. Gardner, *Story of Siena* (1902); W. Heywood and L. Olcott, *Guide to Siena* (1903).

Sienkiewicz, HENRYK (1846-1916), Polish novelist (see POLAND), was born at Wola Okrzejska, near Żuków, in Russian Poland, and studied philosophy at Warsaw. He early devoted himself to literature, and lived for a time in America. Besides *Quo Vadis?* (1896), a study of Roman

society under the Emperor Nero, his chief works are the trilogy, *With Fire and Sword* (1884), *The Deluge* (1887), and *Pan Michael* (1889), dealing with the dramatic events in Polish 17th century history, and *The Knights of the Cross* (1900), where, in a 15th century setting, is set forth the conflict between Slav and Teuton. These historical novels of Sienkiewicz have been called 'a kind of national gospel,' in that they kept alive in the dark years after the eighteen-sixties the national pride in the past glories of Poland. His brilliant narrative and realistic presentations of history are coloured with a strong sense of humour, but are not free from crudity and melodrama. In 1905 he was awarded the Nobel Prize for Literature. For many years he worked hard in the cause of Polish independence. See Monica Gardner, *The Patriot Novelist of Poland* (1926).

Sienna. See SIENNA; also BURNT SIENNA.

Sierra, the name applied in Spain and in Spanish-speaking countries to a range of mountains. It is usually derived from the Latin *serra*, 'a saw,' but more probably comes from the Arabic *sehrak*, 'a desert place,' whence also Sahara.

Sierra, GREGORIO MARTINEZ, Spanish novelist and playwright, was born at Madrid in 1881, and early devoted himself to journalism. His first works were volumes of short stories or novels, but since 1907 he has written, besides adaptations and translations, over forty plays, of which the best known are those translated as *The Cradle Song* (1911), *Mama* (1912), *Madame Pepita* (1912), *Dawn* (1915), *The Kingdom of God* (1915), *The Romantic Young Lady* (1918). While his earlier work is more idyllic and his later work more socialistic, his style is always clear and direct, and his dramatic effects are achieved with strict economy of material. With a healthy optimism, tinged with a certain ironic humour, he shows unbounded sympathy with humanity, and his studies of women are especially true. In 1916 he undertook the management of a repertory theatre in Madrid.

Sierra Leone, a British colony—since 1888 a separate and distinct colony—on the west coast of Africa, stretching 180 miles along the coast from French Guinea in the north to Liberia in the south, with an area of 4000 sq. m. (including the Banana, Sherbro, and other islands). In 1896 a hinterland of 27,000 sq. m. was proclaimed a protectorate, and was organised after the troubles about the hut-tax in 1898 (which for a time caused some anxiety). New arrangements were made in 1913 and in 1914. Pop. of protectorate (1921) 1,456,148. The name Sierra Leone is more strictly confined to a densely wooded peninsula, 26 miles long by 12 broad, jutting out to the NW., just south of the Sierra Leone (i.e. the river Rokelle) estuary, which rises to 3000 feet in Sugar Loaf Mountain. The climate is very hot and very moist. The rains last from April to December, and the annual rainfall ranges from 144 to 170 inches. The thermometer varies between 64·5° and 100·5° F. The low-lying districts are infested with a good deal of fever and malaria; but the higher parts are comparatively healthy. Sierra Leone is often called the 'White Man's Grave,' but the title would be just as appropriate to any of the adjacent coast-regions of that part of Africa. The resources of the colony are by no means fully developed. The population, 37,039 in 1871, 75,572 in 1911, was 85,163 in 1921 (1161 Europeans). They are nearly all negroes, about one-half the descendants of liberated slaves, the others belonging to almost all the tribes of that part of Africa. But all the negroes are alike

indolent, and the soil does not yield anything like what it is capable of yielding. Coffee, cocoa, tapioca, ginger, maize, cassava, and cotton are grown; but the bulk of the exports (palm-oil and kernels, ground-nuts, kola-nuts, benni-seed, ginger, hides, india-rubber, and gums) comes from the interior. Clothing, provisions, coal, wine and spirits, and tobacco are the principal imports. The capital is Freetown (q.v.), an important port and coaling station. The colony is provided with good roads, and has a narrow gauge railway system connecting Freetown with Pendembu and Kamabai. Freetown Bay College (1828), near Freetown, was founded by the Church Missionary Society, with which the Wesleyan Missionary Society has been associated since 1918. It was affiliated in 1876 to Durham University. There are several good schools in the colony. Sierra Leone gives title to an Anglican bishop, and contains many Methodists, besides a large body of Mohammedans. The governor is assisted by a nominated executive council and a legislative council, of whom three members are elected by male voters, the rest being official or nominated, including three paramount chiefs of the protectorate.

This district was discovered and named (from the lion-like thunder on its mountain-tops, Sierra Leone, 'Lion Mountain') by the Portuguese navigator, P. de Cintra, in 1462. In 1787 a body of freed slaves were planted here as a colony; but the enterprise was not a success. Four years later a second attempt was made by the Sierra Leone Company (which included amongst its promoters men like Granville Sharp, W. Wilberforce, and Sir R. Carr Glynne). But this scheme, even though supported by the arrival of 1200 freed negro slaves from North America, was not an unqualified success, and in 1807 the company transferred their rights to the crown. Slavery survives in the protectorate.

See N. W. Thomas's *Anthropological Report* (1916), Goddard's *Handbook of Sierra Leone* (1925), Migeod's *View of Sierra Leone* (1926), and F. W. B. Thompson's *History* (1926).

Sierra Madre ('Main Chain'), a general name for the mountains that in Mexico stretch northward from about Guadalajara to Arizona, forming the western wall of the plateau, and separating Chihuahua from the maritime states of Sinaloa and Sonora. Along the eastern foothills of the range, in north-west Chihuahua, the country is very fertile. The so-called Sierra Madre Plateau, on the United States frontier, is a northern continuation of the Chihuahua plateau.—The name has often been more widely extended, however, to include the central and eastern ranges of the Cordilleras.

Sierra Morena, a mountain-range, or rather a broad mountain-ridge in the south of Spain, forming the southern edge of the great central plain of the peninsula. It separates the basin of the Guadiana on the north from that of the Guadalquivir on the south, and ranges in height from 2000 to 5500 feet. Valuable mines of lead, silver, quicksilver, sulphur, and lignite, as at Thaisis and Río Tinto, occur in certain parts of the system. It is frequently mentioned in *Don Quixote*, and is the scene of many of the incidents therein described.

Sierra Nevada (i.e. 'Snowy Range'), (1) a mountain-range of southern Spain, stretches east through the province of Granada to the frontiers of Almería, is 60 miles in length, from 20 to 30 in breadth, and covers an area of 1060 sq. m. It forms a portion of the watershed between the streams that flow into the Mediterranean and those that flow into the Atlantic. The peak of Mulhacén (11,421 feet) is the highest point of the

Spanish Peninsula. The range receives its name from the perpetual snow which covers the highest summits (down to 11,000 feet). The system is connected with other mountain-masses in Spain, to north, east, and west, and its edges are much indented by deep valleys.—(2) A range of mountains in California, forming the eastern boundary of its Great Central Valley, and extending from north-west to south-east 450 miles, until in the neighbourhood of 35° N. this and the Coast Range meet and become continuous. Among the higher peaks of the Sierra Nevada are Mount Whitney (14,501 feet high), Mount Williamson (14,384), Mount Russell (14,190), Mount Shasta (14,162), Mount Langley (14,044). Granite and metamorphic slate are the principal rocks; in some parts volcanic rocks are abundant. The sides of the range are covered with great forests. Gold embedded in quartz is found in large quantities, and silver-mines have been opened on the east side. The Southern Pacific Railroad crosses the range at an altitude of 7042 feet.—(3) *Sierra Nevada de Mérida* is the principal chain of the Andes in Venezuela, rising to over 15,300 feet.—(4) *Sierra Nevada de Santa Marta* is a system in the extreme north of the republic of Colombia, flanking the sea, and stretching westward from near Venezuela to the low swamps and marshes of the Río Magdalena (about 120 miles). The central knot consists of two tables, with from eight to ten separate summits, all capped with snow, the highest point being 16,733 feet. The leading rocks are granite, syenite, and various slates, sandstones, quartz, and older euptive rocks. The northern slopes are densely wooded with virgin tropical forests from 4000 feet downwards; the southern slopes are naked rocks above 6300 feet. The valley of the Río Cesar is especially fertile, and in the mountains the Arhuacos Indians have even coca plantations. Copper, silver, and gold are found, and coal in the Río Cesar valley.

Sieyès, EMMANUEL JOSEPH, COMTE, who, as the Abbé Sieyès, figures prominently in the French Revolution, was born, the fifth child of an honest bourgeois family, at Fréjus, 3d May 1748. He had his education from the Jesuits at Fréjus and the Doctrinaire Fathers at Draguignan, and first wished to be a military engineer, but was condemned to the clerical calling by the weakness of his health. He studied theology at Saint-Sulpice, where his originality and boldness of speculation caused no small misgiving to his masters, and completed his course at the seminary of Saint-Firmin. He became canon in the diocese of Tréguier (1775), next chancellor and vicar-general of the diocese of Chartres, and was sent by the latter to the Chambre Supérieure of the Clergy of France. Between the dissolution of the Assembly of Notables and the reunion of the Constituent Assembly he published three famous pamphlets which carried his name over the length and breadth of France: *Vues sur les Moyens d'Exécution* (1788), *Essai sur les Privilèges* (1788), and, the most famous of all, *Qu'est-ce que le Tiers-État?* (January 1789). His answer to the last question was 'Everything'; 'What has it been hitherto?' was his next question; its answer, 'Nothing.' 'What does it desire to be?'—'Something.' He was elected one of the deputies for Paris, and it was on his motion (June 10, 1789) that the tiers-état sent a final invitation to the noblesse and clergy to join them, with the intimation that if they refused they would constitute themselves into the States-general. Seven days later the National Assembly was formed, the name being due to the suggestion of Sieyès. After Mirabeau made his memorable answer to the king's messenger, the Marquis de Dreux-Brézé (June 23), Sieyès reassured the members with the characteristically quiet words, 'Gentlemen, you are to-day what you

were yesterday.' The deadly enemy of privilege, cold, inflexible, fearless in logic and trenchant in phrase, Sieyès gained great influence, and the division of France into departments for administrative purposes, declared in the last two months of 1789, was mainly his work. He took part in the memorable declaration of the Rights of Man (26th August 1789), and opposed the royal veto, during the great debate on which question Mirabeau invoked the counsel of Sieyès as that of a man 'whose silence and inaction I regard as a public calamity.' But he kept aloof from Mirabeau's alliance, opposing his policy alike in the last measure and in his refusal to the Assembly of the right of nominating the regent in the event of the king's death. He was elected to the National Convention, sat in the centre, voted for the king's death *sans phrase*, it is said (though he denied adding these words to the one word *mort*); but as the Revolution grew sank into 'philosophic silence,' his heart filled with disdain alike at its illogical excesses and the bombastic rhetoric of its leaders. Asked long afterwards what he had done during the Terror, he is said to have replied, 'J'ai vécu.' He opposed the new constitution of Year III. (1795), and declined a seat on the Directory named by the new Corps Législatif, which entered on its functions on the 27th October of that year, but had a share in the *coup d'état* of 3d September 1797 (17th Fructidor). In 1798 he went on mission to Berlin, was elected to the Directory in 1799, and now, like Barras a traitor to the Republic, he plunged into a web of dark intrigues with a view to find a soldier who would be content to be an instrument. Bonaparte returned from Egypt on October 25, 1799, and together they plotted the revolution of the 18th Brumaire (November 9, 1799), the result of which was the institution of the Consulate of Sieyès, Bonaparte, and Roger Ducos. Once more he drew upon his skill as a framer of constitutions, his final effort being a masterpiece of complexity beyond the calculating machine of Pascal, its aim to break the force of democracy by dividing it, to triumph over the passions of men by cunningly balancing them the one against the other. But he soon discovered in his new ally a master. Finding himself befooled by Bonaparte, he threw up his consulship in disgust, his last illusion shattered for ever. His fall was somewhat gilded over by the title of count, a sum of 600,000 francs, and the estate of Crosne. The presidency of the senate was offered him later, but declined. He wrapped himself in morose meditations during the Empire, filled with silent irony and scorn for that humanity which had so little realised his views. Exiled at the Restoration, he lived in Belgium for fifteen years, returned in 1830, and after a long illness in which his mind often wandered to the Terror and the sinister name of Robespierre, died at Paris, 20th June 1836.

Sigillaria (Lat. *sigillum*, 'a seal'), a genus of fossil plants ranging from the Upper Devonian to the Permian, and attaining its maximum development in the Upper Carboniferous. The *Sigillaria*, forming as they do the chief constituents of many coal-seams, particularly in the Middle and Upper Coal Measures, are regarded as one of the most important genera of Palæozoic plants. They show a characteristic arrangement of the leaf scars

which are usually in vertical series, the scars of adjacent series alternating. Two main divisions of the genus are recognised—the *Eusigillariae* which have ribbed stems, and the *Subsigillariae* in which ribbing is absent. The latter are characteristic of the Upper Coal Measures and Permian. Over one hundred species of the plant have been described.

The *Sigillariae* were among the largest trees in the forests of Palaeozoic times. Stems, in most cases nearly cylindrical, have been found with a length of nearly one hundred feet, some unbranched, others branching dichotomously. Quite frequently leaves are found attached, particularly to the upper part of the stem. The fructifications, which were for long unknown, are large cones, called *Sigillariostrobus*. The roots, known under the name of *Stigmaria*, usually start from the stem in four main branches, which divide dichotomously several times, and then extend for long distances like great cylindrical cables. They are abundant in the 'underclays' of the Coal Measures. Dr D. H. Scott has suggested that the unbranched *Sigillariae* had a habit something like that of the Australian grass-tree, the tall stem ending in a sheaf of grass-like leaves.

The affinities of the *Sigillariae* were for long matters of dispute among botanists. Dr D. H. Scott has suggested that the unbranched *Sigillariae* known to have preservation of internal structure, regarded the presence of secondary growth as a character unknown in cryptogams, and concluded 'that the *Sigillariae* and *Stigmaria* constituted a special family, entirely extinct, probably belonging to the great division of gymnosperms dicotyledons.' At that time the fructifications were unknown. Subsequent research led to the discovery of secondary growth in many cryptogams. Moreover, *Sigillariostrobus*, the cone of *Sigillaria*, has proved to be cryptogamic in character. *Sigillaria* is now accepted as belonging to the lycopodiaceous cryptogams, and as having very close affinities with the well-known genus *Lepidodendron*. See Scott's *Studies in Fossil Botany*, Part I, 1920.

Sigismund, German emperor (1411-37), the son of the Emperor Charles IV., was born on 28th June 1368. He was made king of Hungary when only nineteen, succeeding to that dignity through his wife. In 1396 at the head of a numerous army he attempted to relieve the Byzantine empire from the Turks, but was terribly defeated at Nicopolis (28th September). Some years later he conquered Bosnia and Herzegovina and reduced Serbia to his sway. In 1411 he was proclaimed king of the Romans on the death of Rupert; he was crowned emperor in 1414 and again in 1433. One of his earliest acts as emperor was to induce Pope John XXIII. to call together the Council of Constance (q.v.) for the purpose of putting an end to the Hussite and other schisms. But although he supported the party of reform, he made no effort to uphold the safe-conduct he had granted to Huss, and permitted him to be burned by his enemies. In return for this breach of faith his

succession to the throne of Bohemia, after his brother's death, was opposed by the Hussites; and they maintained their opposition so stoutly that it was 1436 before Sigismund, making concessions, could put the crown of Bohemia on his head. But in the year following he died at Znaim, on 9th December. This emperor possessed many of the qualities of a capable ruler, and made praiseworthy attempts to introduce various reforms in the administration of the empire, but his efforts seem to have been frustrated in great part by his own lack of decision and by his chronic want of money. Brandenburg, given him by his father, Charles IV., he bestowed in 1415 upon his right-hand man, Frederick of Hohenzollern (q.v.).

See a monograph by A. Main (1903). For the Polish Sigismunds, see POLAND.

Signmaringen. See HOENZOLLERN.

Signalling is a method of transmitting intelligence to a distance, great or small, by means of coloured flags, shapes, semaphore, waving one or two flags, flashes, sounds, &c. Incomparably the most powerful medium yet known for this purpose is the electric current (see TELEGRAPH, TELEPHONE). For railway signals, see RAILWAYS.

Sigillaria restored: a, *Brongniart*, who in 1839 described the first *Sigillaria*, b, *S. elegans*. (After Dawson.)

CODE FLAG & ANSWERING PENDANT

BLUE RED YELLOW WHITE BLACK

Fig. 1.

The ancients seem to have elaborated a fair system of night-signals by torches for military purposes (see BEACON); but in naval affairs the ships sailed so close together that orders could be

communicated by word of mouth, while the turning of a shield from right to left sufficed as sailing directions to the several lines. In the time of James II. a ship's signal could only be expressed by flags, in confusing number, hung in different parts of the vessel. Thanks to Sir Home Popham, Marryat, and other inventors, the system has been invented of hanging a number of flags under one another, each combination having an arbitrary conventional meaning attached to it. In 1857 the British Board of Trade devised a new set of eighteen coloured flags, and published a code under the name of *The International Code of Signals*. In 1901 this code was cancelled, and eight new flags were added to the old eighteen, thus completing the alphabet. This change involved rewriting the code-book.

In the present code, flag-signals are made by hoisting two, three, or four flags together, one below the other. In the code-book each set of hoists is printed alphabetically. The meanings of the signals are also printed alphabetically under the principal word of the signal, e.g. all 'Ice' signals are printed under the code-word 'Ice.'

To make a signal on board ship A, ship A hoists her ensign with the code flag under it; then hoists the signal where it can be best seen (not necessarily at the mast-head). The ship B, signalled to, hoists her Answering Pennant at the 'dip' when A begins signalling, and hoists it 'close up' when the signal is clearly read. Then A hauls down the signal-flags. If B cannot understand A's signal, B keeps her Answering Pennant at the 'dip,' and hoists a 'not understood' signal.

Two-flag hoists are 'Urgent' or 'Important Signals.' For general conversations, the three-flag hoists, called the 'General Vocabulary,' are most in request. Geographical signals are four-flag hoists, of which the uppermost flag is A or B. Names of ships of the British royal navy are four-flag hoists, of which the uppermost flag is G. Merchant ships' names are four-flag hoists, of which the uppermost flag is H or succeeding letter.

Various foreign maritime nations have adopted this code, and have, of course, translated it. It is obvious that, in using and interpreting signals, the signalman must be in possession of the Signal Code-book, a bulky quarto of 570 pages.

For signalling by shapes, the shapes used are a cone point up, a cone point down, a ball, and a drum.

Each letter of the alphabet is made by a combination of three of these shapes. A and U are shown in fig. 2.

The same alphabet is used for semaphore signalling, the cone point up being replaced by arm up; cone point down by arm point down; arm level for ball (all these are on the side opposite a short level arm at the bottom of the post, known as the

'indicator'); arm level, on same side as indicator, is the drum. The letters A and U on this semaphore are shown in fig. 3.

Fig. 2.

Fig. 3.

These signals, whether shapes or semaphore, are called 'Distant Signals,' but their use at sea appears to be very rare.

Another alphabet, given below, is framed for use in flag-waving with two flags, and for a corresponding semaphore.

ARM SEMAPHORE ALPHABET.

Fig. 4.

Note.—The letters A to I represent the numerals from 1 to 9 respectively; K represents zero.

Recent years have seen the general introduction at sea of light-flashing and sound-signals, especially in the form of wireless telegraphy. The Morse alphabet given below is invariably used:

Fig. 5.

In signalling, the dot is represented by a short flash or short sound, and the dash by a long flash or long sound. Signals may be made by the ordinary International Code Signal Book. The same Morse alphabet is used in flag-waving with one flag. (See below, *Army-signalling*.)

The international signals used by vessels which are in distress to summon assistance are: in the daytime, a gun or other explosive signal fired at intervals of about a minute; the International Code signal of distress indicated by NC; the distant signal, consisting of a square flag, having either above or below it a ball or anything resembling a ball; a continuous sounding with any fog-signal apparatus; and, at night, a gun or other explosive signal fired at intervals of about a minute; flames on the vessel (as from a burning tar-barrel, oil-barrel, &c.); rockets or shells, throwing stars of any colour or description, fired one at a time, at short intervals.

A steamer steaming shows green starboard light, red port light, and one mast-head white light or two, the second one aft of and higher than the forward one; and a white light astern, or a flare up astern when necessary; steam-tugs double or triple the masthead light; sailing-vessels carry a green starboard light and a red port light; steamers and sailing-ships unable to manœuvre show two red lights vertically at night, and two balls vertically in daytime; cable-laying ships show red, white, red lights vertically at night, and red ball, white diamond shape, and red ball, vertically, in daytime. Vessels fishing have special lights. See also FOG-SIGNALS.

Ships wanting a pilot hoist the Union Jack with a white border, or PT, or S, or a cone with two balls above it. At night the signal is a blue light, or a white light shown at short intervals during a minute.

The use of signals to indicate to the mariner the approach of wind storms has become common in maritime countries. The British signals are as follows: A 'cone point down' indicates the approach of a gale or strong winds from E., SE., SW., or W., veering (right-handed); and a 'cone point up' indicates the approach of a gale or strong winds from SE., E., or NE., backing (left-handed), or from NW., N., or NE., veering (right-handed). At night the cones are replaced by a triangle of lights.

See *International Code of Signals*, *The British Signal Manual*, *The Signal Letters of British Ships*, *Regulations for Preventing of Collisions at Sea*, *Monthly Notices to Mariners*; weather signals published by the various government meteorological offices.

Army-signalling.—The system of visual signalling adopted in the British army is a combination of short or long flashes by lamps at night, and the alternate appearance or obscuration of any given object by day (revolving shutters or discs, semaphores, collapsible cones, flags, or even jets of steam), and if visible symbols are not available, short and long sounds on a fog-horn, bugle, or steam-whistle may be used. By any of these means the dot and dash of the Morse alphabet,

Fig. 6.

Morse flag-signalling: from *a* to *b* and back to *a* is a dot, from *a* to *c* and back to *a* is a dash. The code

and numbers laid down in the army and navy signal-book or secret codes are sometimes used instead of spelling the words by the Morse alphabet. This prevents unauthorised persons reading the signals. The semaphore systems already described are also made use of, and are indeed quicker than the Morse system of dots and dashes, in which some of the letters require four movements. While the maintenance of these systems of visual signalling is essential for military field operations, the great extension of modern battle-fields, as well as the difficulties of communication produced by fog and by close country, where view is short, necessitates the supplementing of this means of communication by the use of field telephones and of wireless telegraphy. Thus the commander of a battery may often have to observe the effects of its fire, and order the necessary corrections, from a point where his guns are invisible to him.

The difficulties were overcome to some extent in the 19th century by the use of field telegraphy and telephony. Conditions were exceedingly unfavourable to visual signalling in Manchuria during the Russo-Japanese war and a beginning was made in wireless telegraphy. Progress, however, was slow until the years of the Great War. The need for highly organised intelligence and communication brought an elaborate system of field telephones, but the superiority of wireless communication steadily asserted itself, and wireless telegraphy and telephony became of first-rate importance. Other means of sending messages were, of course, utilised when necessary and possible, dogs and carrier-pigeons being frequently resorted to for conveying messages.

Signature. See BOOK, DEED.

Signature in Music is of two kinds. (1) The key-signature, placed on the staff after the Clef (q.v.), indicates in a group the number of sharps or flats of the Scale (q.v.) in which the composition is written. The order of the sharps or flats remains the same in which they have been introduced in the regular succession of scales. The sharpened seventh of the minor scale occurs in the music as an accidental (see ACCIDENTALS). (2) The time-signature, placed after the key-signature, indicates the rhythm of the composition, commonly by a fraction, the denominator referring to one of the divisions of a semibreve, and the numerator to the number of those divisions contained in one bar. In most classical music, however, for four crotchets in a bar, a semi-circle (in the shape of the letter C) is used—a relic from mediæval times, when the circle indicated perfect or triple time, and a semi-circle imperfect or duple time—while usually a semi-circle with a bar through it stands for two minims in the bar.

Signatures, THE DOCTRINE OF, an inveterate belief in early medicine that plants and minerals bore certain symbolical marks which indicated the diseases for which nature had intended them as special remedies. These figures, of course, were not the result of chance, but the evidence of Providence, being really the characters and figures of those stars by whom they are principally governed and endowed with particular virtues. And the doctrine brings us into the wider region of magic in its fundamental confusion between an object and its image, the word and its idea. Many names witness to a belief in this theory, as *mandrake*, *kidneywort*, *scorpion-grass*, and the *Euphrasia* or eyebright. In the case of the last, for example, the plant was supposed to be good for the eyes, because of a black pupil-like spot in its corolla; and by an analogous process of thought the yellow turmeric was thought good for jaundice, the bloodstone for stopping bleeding. Similarly white things were

regarded as refrigerant, red as hot. So in small-pox red bed-coverings were used, with the view of bringing the pustules to the surface of the body; red things were to be looked upon by the patient; burnt purple, pomegranate seeds, mulberries, and other red ingredients were dissolved in his drink. John of Gaddesden, physician to Edward II., directs his patients to be wrapped up in scarlet dresses, and claims by this means to have recovered the young prince quickly from an attack of small-pox. Wraxall, in his *Memoirs*, tells us that this was done so late as 1765 with the Emperor Francis I. when ill with smallpox. See PLANTS; and T. J. Pettigrew, *On Superstitions connected with Medicine and Surgery* (1844).

Signboards were known to both Greeks and Romans. There are allusions to them in classic writers; and specimens have been found at Pompeii and Herculaneum, sometimes painted, but oftener carved. A bush was the sign of many taverns so late as the reign of James I., and the antiquity of that sign may be inferred from the analogy of our proverb, 'Good wine needs no bush,' to the Latin 'Vino vendibili suspensâ hederâ non opus est.' During the illiterate middle ages every trade had its emblem, some of which have survived to our day, as the chemist's pestle and mortar, the pawnbroker's three balls, and the barber's pole, with in Scotland (as on the Continent) the brazen basin, which recalls Don Quixote. Besides these trade emblems, every individual trader might have his own special device: Southey's father, a Bristol linen-draper, for his chose a hare. During the 16th and 17th centuries huge painted signs came greatly into vogue. They were suspended either from projecting metal-work, from a post or an obelisk, or from a sort of miniature triumphal archway, and sometimes cost great sums—e.g. £1057 for the 'White Hart' at Scole in Norfolk, erected in 1655. These creaking and ponderous signboards proved a source of annoyance, sometimes of positive danger, as when in 1718 one in Bride's Lane, Fleet Street, dragged down a house front, and killed in its fall four persons. So in 1762-70, under act of parliament, the London signboards were either wholly removed or at least affixed to the fronts of the houses; and this example was gradually followed throughout the kingdom, though here and there signposts linger, or have been restored—even in London. A good many signboards have been painted by great artists, Holbein, Correggio, Paul Potter, Hogarth, Wilson, Morland, David Cox, 'Old' Crome, Sam Bough, and Sir J. E. Millais (some of which are still extant); and nearly every sign had its curious origin, hard though it may be to come at. Thus, there were the religious signs ('Salutation,' 'Lamb and Flag,' &c.), historical signs (as the 'Royal Oak' and 'Marquis of Granby'), heraldic (coats of arms, crests, and badges), humorous (as the 'Good Woman,' without a head), and a host of others. Not the least curious feature about old signs is the havoc played on their names by 'folk-etymologies.'

Signet, in England, one of the seals for the authentication of royal grants; for its use and for the signet office, now abolished, see SEAL. The signet in Scotland is a seal which seems to have been originally intended to authenticate royal warrants connected with the administration of justice. The principal class of solicitors in Scotland are called Writers to the Signet, from their having been originally clerks in the office of the king's secretary, it being their duty to prepare all warrants for charters or grants to be passed under either the Great Seal or Privy-seal, such warrants being called from an early period 'signatures,' because they bore the signet of the king.

Writers to the Signet and Solicitors before the Supreme Courts were long the only solicitors allowed to act as agents in the Supreme Courts. But by the Law Agents Act of 1873 any person duly admitted a law agent can practise in any court in Scotland. See SOLICITORS.

Sign-manual, ROYAL, the superscription of the sovereign, which must be adhibited to all writs which have to pass the Privy-seal or Great Seal. When attached to a grant or warrant it must be countersigned by one of the principal secretaries of state, or by the Lords of the Treasury. For certain deeds of minor importance a *cachet* or stamp of the royal signature is used.

Signorelli, LUCA, Italian painter, was born about 1441, at Cortona, being a distant relative of Vasari, the historian of Italian art. He studied under Piero della Francesca of the Umbrian school, but seems to have learned most from observation of the human form. During the first half of his life he had apparently no settled home; at all events he worked in various towns in Italy. At Loretto he painted a number of frescoes of sacred subjects, commissioned by Pope Sixtus IV.; in the Sistine Chapel the fresco called the Acts of Moses; and for Lorenzo de' Medici the picture known as the School of Pau. This last design he subsequently repeated on the wall of Pandolfo Petrucci's palace at Sienna; in a convent of that same city he painted, after 1497, eight frescoes illustrating the Life of St Benedict. But the greatest achievement associated with his name is a number of frescoes, depicting such subjects as the Fall of Antichrist, Punishment of the Wicked, the Last Days of Earth, done on the walls of a chapel of the cathedral in Orvieto. The boldness and grandeur of invention shown in these designs, and the powerful modelling of the nude forms, suggest comparisons with Michelangelo. Signorelli was one of the painters summoned to Rome by Pope Julius II. in 1508 to adorn the Vatican, and along with his colleagues was dismissed to make way for Raphael. In his native town he left many proofs of his artistic skill, and died there in 1525.

See Crowe and Cavalcaselle's *History of Painting in Italy* (1864-71), R. Vischer's *Signorelli* (Leip. 1879), and Miss Cruttwell's (1902).

Signourney, MRS LYDIA HUNTLEY (Huntley being her maiden name), American authoress, was born at Norwich, Connecticut, 1st September 1791. For five years she taught a class of ladies in Hartford; in 1815 she published *Moral Pieces in Prose and Verse*; and in 1819 she married a Hartford merchant. In 1822 she published a descriptive poem on the *Traits of the Aborigines of America*; and in 1824 a *Sketch of Connecticut Forty Years Since*. These were followed by *Pocahontas and other Poems*, *Lays of the Heart*, *Tales in Prose and Verse*, &c., and *Letters to Young Ladies* and to *Mothers*, both of which passed through many editions, in England as well as America. In 1840 she visited Europe, and on her return wrote her *Pleasant Memories of Pleasant Lands*. She compiled amusing and instructive books for the young, and was a constant contributor to magazines and other periodicals of poems, whose subjects, style, and sentiment gave her the designation of 'the American Hemans.' She died at Hartford, 10th June 1865. See her autobiographical *Letters of Life* (New York, 1866).

Sikhs, a religious sect of Northern India, which became a great military confederacy. The sect was founded by Baba Nânak (born in 1469), who rejected the institution of caste, idolatry, and

superstition, preached the existence of One spiritual God, and inculcated a higher moral life. He was followed in the headship of the sect—'Sikhs' means 'followers' or 'disciples'—by ten 'gurus' or chief-priests. The third of these excavated the sacred tank at Amritsar; and his son, Arjun Mal, built, towards the end of the 16th century, the holy temple, in the tank at Amritsar, which became the headquarters of the Sikh religion. The same guru first edited the *Adi Granth*, the sacred book of the Sikhs. As time went on the adherents of the sect, principally Jats by race, gradually becoming conscious of their numbers and their growing power, began to adopt something of a military organisation in addition to their religious discipline. This end—converting them into a powerful military community—was deliberately pursued by the guru Govind Rai (1675–1708); he adopted the appellative Singh (or Sing; better Sinh, 'lion') as a generic family-name for all members of the sect, strengthened the bonds of personal discipline, and revised the sacred book so as to bring it into harmony with the altered aims and position of the Sikhs. See INDIA.

On the downfall of the Mogul power, shortly after the middle of the 18th century, the Sikhs formed themselves into a number of tribal and territorial confederacies, some of which were virtually independent states. Their religious fanaticism was fanned by a body of devotees, who dedicated themselves to warlike pursuits; and the Sikhs greatly extended their possessions. It was, however, Ranjit Singh (q.v.), a young and warlike chieftain, who converted the Sikh confederacies into a powerful and formidable military power, by welding the separate confederacies into one organic whole and carrying his arms westwards, northwards, and southwards. On the east alone he made no conquests; he had in 1809 concluded a treaty of peace with the British, whose authority reached to the Sutlej, which was the eastern boundary of the Sikh dominions. This agreement Ranjit faithfully kept; but at his death he left an army of 124,000 men, animated by a warlike spirit and inspired by religious enthusiasm—a force that had been thoroughly organised and drilled by French officers on the European system. But there was none amongst his immediate descendants capable of taking up the sceptre he let fall, and wielding it with the same energy and skill. Amid the anarchy that followed his death, the soldiers of his armies clamoured to be led against the forces of the British; and accordingly in December 1845 they crossed the Sutlej and invaded British territory. Their advance guard was, however, routed by Sir Hugh Gough at Mudki (18th December), though not without heavy loss to the British, 'Fighting Bob' Sale being amongst the slain. The main body entrenched themselves at Ferozshah, 12 miles east of the river; but their camp was stormed, after two days' desperate fighting, by Sir Hugh Gough and Sir Henry Hardinge (governor-general) on December 21st and 22d. Another Sikh army that crossed the river was defeated and driven back by Sir Harry Smith, at Aliwal (28th January 1846); and on 10th February Gough and Hardinge totally crushed and dispersed the Sikh forces at Sohraon. The British at once captured Lahore, and on the 9th March following peace was signed between the combatant parties, the Sikhs ceding the districts between the rivers Sutlej and Ravi, and subsequently, in lieu of a money indemnity, Kashmir, the hill-country of Hazara, and some other portions of territory.

Two years later war broke out again, caused, as the first conflict was, by Sikh fanaticism: two British officers were massacred at Multan in April 1848. And although Lieutenant Herbert Edwardes

attempted to check the movement at its beginning, the war became general. Multan was taken, but the battle of Chillianwala (13th January 1849) was left undecided, in spite of very heavy losses on the British side. At Gujrat, however, on 21st February, Gough finally broke the power of the Sikhs. The Punjab was annexed to British India; and so successfully was its government organised by Dalhousie and the two Lawrences that during the Mutiny the Sikhs not only refrained from joining the rebel sepoys, but lent material assistance in quelling the outbreak. Dhuleep Singh (1837–93) who had succeeded Ranjit Singh as Maharaja of Lahore in 1843, and was deposed in 1849, became dependent on a pension from the Indian Government, lived long in England, professed Christianity, and married in succession two English ladies. He was much addicted to field sports and fell deeply in debt. In 1882 he made inadmissible claims, abjured Christianity, and started for India, but was not allowed to return, and finally lived on his pension in Paris, where he died. His son, educated at Cambridge, became an officer in the Guards and married a daughter of the Earl of Coventry.

The Sikhs constitute about 12 per cent. of the population of the Punjab; and there are connected with the Punjab seventeen protected Sikh states, of which Patiala is chief. In 1921 the Sikhs numbered, in the Punjab, 2,294,207; in the protected states, 813,000; in the rest of India, 155,000. It is an error to regard the Sikhs as a race—ethnographically they are like their neighbours, their language being Punjabi; and their religion it is alleged tends more and more to become a mere sect of Hinduism.

See J. D. Cunningham, *History of the Sikhs* (1849); Sir J. Malcolm, *Sketch of the Sikhs*, (1812); Gough and Innes, *The Sikhs and the Sikh War* (1897); Sir J. J. H. Gordon, *The Sikhs* (1904); Max A. Macauliffe's *The Sikh Religion, its Gurus, Sacred Writings, and Authors* (6 vols. 1909) contains a translation of the *Granth Sahib*, and was approved by the Sikh authorities, who strongly disapproved of Trumpf's *Adi Granth* (1867) and *Die Religion der Sikhs* (1881), as showing Christian missionary bias against their faith.

Si-kiang, a river of China, rises in Yunnan, and flows east till, just above Canton (q.v.), it turns south and pours its waters into the Chinese Sea. Canton and Hong-Kong stand on the eastern arm of its delta, and Macao on the promontory that divides it from this arm, the Canton River.

Sikkim, a protected state in the north-east of India, bordering on Tibet, Nepal, and Bhutan. Area, 2818 sq. m.; pop. (1921) 81,721, mostly Buddhist Rongs or Lepchas, akin to the Tibetans. The state lies on the southern slopes of the Himalayas, has mountains reaching to 24,000 feet and mountain-passes at 16,000 feet. The Chola pass, on the road from Tum-long into the Corumbi valley in Tibet, is 15,000 feet high. Swift torrents flow at the bottom of precipitous ravines; and valleys and lower slopes are clothed with forest. The maharaja, who resides at the village of Tumlong, is advised by a British political officer. His predecessor ceded Dárjiling to the British in 1835, having already acknowledged their 'protection' in 1816. The treaty of 1890 gave Britain exclusive control over its internal and foreign affairs. The district of Dárjiling (q.v.), which borders on Sikkim state, is often called British Sikkim.

See Strahan, *Exploration in Sikkim* (1899); Donaldson, *Lepcha Land* (1900); J. C. White, *Sikkim and Bhutan* (1909).

Sikrol, or SECREOLE. See BENARES.

Silage is the term applied to fodder which has been preserved by the process of Ensilage. Ensil-

age is a French word, tracing through the Spanish, from the Lat. *sirus*, Gr. *siros*, 'a pit,' whence the Spanish verb *ensilar*, 'to store grain in a silo or pit.' It was originally employed to denote the preservation of green forage in an air and water tight silo—the contents being tightly pressed down so as to get rid of and permanently exclude the oxygen of the air, and thereby prevent putrefactive fermentation. The practice, since its introduction into the British Isles, has been considerably extended, so that the term silage is now applied to green fodder which has been preserved by pressure in stacks as well as to that preserved in silos by pressure. The making of silage was originally advocated as it was thought it would render the farmer independent of the weather in seasons when haymaking was attended with difficulty. The practice of ensilage is of great antiquity. From time immemorial grain has been stored in underground pits in eastern countries. In the time of Pliny it was, he tells us, pursued with success in Thrace, Cappadocia, Barbary, and Spain. Varro also speaks approvingly of the process, and asserts that by it wheat could be preserved fresh for fifty years and millet for a century. In early times it was probably employed chiefly to hide stores of grain from invaders. It is now used mainly in the preserving of green food for cattle and horses. The converting of green fodder, as distinguished from ripened grain, into silage is believed to have been first practised in Germany. In 1843, in the *Transactions of the Highland and Agricultural Society of Scotland*, Professor Johnston gave a detailed description of the German system of making 'sour hay.' The practice spread through the Austro-Hungarian empire, where graves or trenches, 4 feet by 6 or 8 feet in breadth and depth, were dug and crammed with green grass or green Indian corn, the whole being covered over with a foot of earth. The distinction of first succeeding in directing general attention to the subject was earned by a Frenchman, M. Goffart, whose book, *Manuel de la Culture et de l'Ensilage des Murs et autres Fourrages verts*, published in 1877, was not only widely read in his own country, but was translated into English and published in New York in 1879. The method had already been tried to a small extent in America, and the perusal of M. Goffart's work aroused the deepest interest and led to numerous and extensive experiments. The general results were satisfactory, and soon the system found its way into Great Britain. Although several trials were made earlier, the systematic and extensive adoption of ensilage in the United Kingdom dates from 1882. In that year the successful experience of Vicomte Arthur de Chezelles, who had been pursuing the system upon a large scale in France, was made known through the press to British farmers. A host of experimentalists were instantly at work, and so keenly was public attention aroused that in 1883 the Ensilage Commission, a private but highly influential body, was formed to collect evidence and consider and make known the merits of the practice. A mass of valuable information was collected and was embodied in the official blue-books issued by the government.

The commission reported strongly in favour of the system, concluding as follows: 'After summing up the mass of evidence which has reached us, we can without hesitation affirm that it has been abundantly and conclusively proved to our satisfaction that this system of preserving green fodder crops promises great advantage to the practical farmer, and, if carried out with a reasonable amount of care and efficiency, should not only provide him with the means of insuring himself to a great extent against unfavourable seasons, and

of materially improving the quantity and quality of his dairy produce, but should also enable him to increase appreciably the number of live-stock that can be profitably kept upon any given acreage, whether of pasture or arable land, and proportionately the amount of manure available to fertilise it.'

From 1883 the progress of the movement in Great Britain was rapid. The British agricultural returns first included statistics as to ensilage in 1884. In that year 610 silos were reported as existing in Great Britain. In the next three years the number increased to 2694. By 1887 it was proved by repeated experiments in England that silage might be made in stacks as well as in silos, and for a few years the stack system was in fairly general use. The practice of ensilage, however, gradually fell into disuse in Britain until about 1910, when the American Tower silo was introduced. This consists of a tall cylindrical building, made of wood, brick, steel, or most commonly of reinforced concrete; the height being from thirty-five to fifty feet and the diameter from twelve to twenty feet. The green material to be ensiled is cut by a power machine into short lengths and is conveyed into the silo usually by means of an air blast. It is firmly packed round the wall by treading, and is thereafter left to settle under its own weight. Fermentation ensues, the nature of the process depending mainly on the amount of moisture contained in the crop. If this is high a slow fermentation occurs, accompanied by a comparatively slight rise in temperature, and the resulting silage is green in colour and rather sour. With drier material a greater rise in temperature takes place, and the product is brown and sweet; in the latter case the loss by fermentation is greater. Intermediate conditions producing what is called 'green fruity' silage are generally aimed at.

In the United States and Canada the crop most commonly cultivated for silage is maize, with or without an admixture of leguminous plants. In tropical countries Great Millet (*Sorghum vulgare*) is used. In Britain the most generally satisfactory crop is a mixture of beans, oats, and vetches. Leguminous crops alone are liable to undergo putrefactive changes in the silo, and are less satisfactory.

The feeding value of well-made silage is nearly twice as great as that of swedes or mangels, and about two-fifths of that of good hay. The proportion of dry matter to water in the cured material is about thirty per cent. of the former to seventy of the latter. An average yield in Britain is about eight tons of mature silage per acre. Silage can be kept indefinitely so long as it is left undisturbed; the upper layer, where it is exposed to the atmosphere, of course becomes mouldy and must be discarded.

Well-made silage is relished by both sheep and cattle, and may be fed in moderate quantities to horses and pigs. The practice of ensilage is now common in clay soil districts, where the cultivation of roots is difficult and costly; also in the wetter parts of the country where the hay crop is very liable to damage.

Silbury Hill. See AVEBURY.

Silchester, a village in the extreme north of Hampshire, 7 miles N. of Basingstoke, famous for the remains of the ancient Romano-British town of *Caer Segeint*, called by the Romans *Calleva*, and by the West Saxons *Silceastre*. The chief visible remains are the amphitheatre, 50 yards by 40, and the walls, 2760 yards in length; excavations have shown the whole plan of the town (100 acres), with the foundations of a basilica, the forum, a temple, baths, &c.; and coins, seals, rings, and much broken pottery have been found. New excavations were made in 1890–1909. See *Archæologia*.

Silene, a genus of Caryophyllaceæ, having the calyx, corolla, and stamens of *Lychnis* (q.v.), three styles and a three-celled capsule opening at the top in six teeth or valves. The species are numerous, mostly natives of the temperate parts of the northern hemisphere, annual and perennial plants; nine or ten of them natives of Britain, and others frequent in flower-gardens. One of the most common British species is the Bladder Campion (*S. Cucubalus*), a perennial, which grows in corn-fields and dry pastures, and has a branched stem fully a foot high, ovate-lanceolate bluish-green leaves, panicles of white flowers, and an inflated calyx, with a beautiful network of veins. The young shoots are sometimes used like asparagus, and have a peculiar but agreeable flavour, somewhat resembling that of peas. They are best when most blanched. The cultivation of this plant was long ago strongly recommended, but it has not obtained a place among garden plants. The sea-side plant *S. maritima* is very similar, with fewer and larger flowers and procumbent barren stems. The Moss Campion (*S. acaulis*) is a pretty little plant, with beautiful purple flowers growing in patches so as to form a kind of turf, one of the finest ornaments of the higher mountains of Scotland, found also in Cumberland and Wales. Many species, some of them British, are popularly called Catchfly, from their viscidness, as *S. anglica*, a species found in sandy and gravelly fields in many parts of Britain. For the Red Campion, White Campion, and German Catchfly, see *LYCHNIS*.

Silenus, a primitive woodland deity of Asia Minor, whom men try to catch in a drunken sleep, in order to compel him to prophesy and sing. Later representations make him a son of Hermes or of Pan, and the chief of the Sileni or older Satyrs, and the inseparable companion and instructor of Dionysus, with whom he took part in the contest against the Gigantes, slaying Enceladus. He is described as a little pot-bellied old man, bald-headed and snub-nosed, his body very hairy, always drunk and bearing a skin of wine, and usually propped up by the other satyrs or astride of an ass, since his own legs could not be trusted.

Silesia (Ger. *Schlesien*; Pol. *Śląsk*; Czech *Slézsko*), a region of Europe forming, before the Great War, a Prussian province and an Austrian land, now forming two Prussian provinces (Upper and Lower Silesia), one Polish, and one Czechoslovak.

Early in the 10th century, Silesia, except the extreme western districts, was under the dominion of Poland, and towards the end of the 12th century was divided into two duchies (Breslau or Lower Silesia and Ratibor or Upper Silesia) ruled by Polish dynasties. In the following century great numbers of German immigrants settled in the country and gradually Germanised its semi-Slavic inhabitants. Duke Henry II. of Lower Silesia perished in the memorable battle of Liegnitz (1241), in conflict with the Mongol invaders. By the beginning of the 14th century Silesia was divided up amongst a score of petty rulers, nearly all of whom acknowledged King John of Bohemia as their feudal superior instead of the king of Poland in the years 1327-29. The Silesian dukes put no obstacles, as a rule, in the way of the Reformation; but the emperors, who as the heirs to the kingdom of Bohemia became the suzerains of Silesia, treated the people with cruel intolerance, and pursued that policy down to the first decade of the 18th century. The great duel between Austria and Prussia for the mastership of the Silesian territories grew out of a contract by which in 1537 the Duke of Liegnitz left his lands to the

Electoral of Brandenburg in the eventuality of his house becoming extinct in the male line. On the conclusion of the first Silesian war (1742) the duchies were divided, Prussia getting by far the greater number and greater area; and the result of the second Silesian war and the desperate struggle of the Seven Years' War confirmed Frederick the Great in the possession of the lands he had so greatly coveted. Frederick, however, took the most active and judicious measures to improve his conquest, and reform its administration and put it on a sound basis. Silesia took a very zealous part in the final struggle against Napoleon in the early years of the 19th century. For the history of Austrian Silesia, see CZECHOSLOVAKIA, Vol. III. p. 649. It was a separate Austrian crownland from 1849 till the break-up of the empire, when it became part of Czechoslovakia, except part of the Teschen district which, after some bloodshed, went to Poland by agreement, the plebiscite provided for by treaty being abandoned. A small piece of Prussian Silesia, to the east of Troppau, was added, and connected the two areas which a wedge of Moravia had till then entirely separated. The Treaty of Versailles transferred a small north-eastern corner (about Bralin) of Lower Silesia from Prussia to Poland, and provided for a plebiscite for the greater part of Upper Silesia. In spite of the filibustering activities of the Polish leader Korfanty this was held in 1921, and resulted in a vote of about three to two in favour of Germany. The territory was divided by a line passing through the mining and manufacturing district, giving the mines mostly to Poland, many of the towns and factories they fed to Germany, and satisfying nobody. Upper Silesia decided by an overwhelming vote in 1922 to remain a Prussian province rather than become a separate state of the German Reich. For the Silesian Schools of Literature, see GERMANY (Vol. V. p. 193), and OPITZ.

Silesia, AUSTRIAN. See SILESIA, SILESIA (CZECHOSLOVAK), AUSTRIA, and CZECHOSLOVAKIA.

Silesia, CZECHOSLOVAK, a province of Czechoslovakia, answering roughly to the former Austrian Silesia (see SILESIA). Area, 1708 sq. m.; pop. (1921) 672,268. Subsidiary chains of the Carpathians and Sudetic Mountains diversify the southern and western frontiers; the province is watered by the systems of the Vistula (in the east) and the Oder (west). The climate, though somewhat raw, is healthy, and the soil produces good crops of rye, oats, barley, potatoes, beet-root, hay, &c. Mining and manufacturing industries both flourish. The mines yield coal, iron, and other minerals. The principal industries are the smelting of iron, making of machinery, the manufacture of various textiles (worsted, cloth, linen and linen thread, cottons, &c.), brewing, distilling, and the preparation of chemicals. The principal town is Troppau (Opava).

Silesia, LOWER (*Niederschlesien*), a south-eastern province of Prussia, traversed from S.E. to N.W. by the Oder, which forms in its middle course a deep valley, with a westward extension from near Liegnitz, crossed in its western corner by the Spree and the Black Elster. The south-western parts are broken and made uneven by the Sudetic Mountains and their outlying ranges. North and east of the Oder, and in the west of the province, are great tracts of marsh and sand, in which there is much forest. But between the Oder and the mountains the soil is exceptionally fertile, producing the usual cereals, besides flax, beet-root, chicory, hops, and fruit. Much has been done to encourage the breeding of sheep, horses, and cattle. The two Silesian provinces form one of the greatest industrial regions of Germany. Very important in

Lower Silesia are cotton and linen. Besides these, woollen, metal, glass, pottery, and many other industries flourish. There is a coalfield around Waldenburg. Area of province, 10,276 sq. m.; pop. (1925) 3,121,153. The capital is Breslau.

Silesia, POLISH, a palatinate in the south-west of Poland, reaching up into the Beskid Mountains, and including the source of the Vistula and part of the upper basin of the Oder. It is a very rich mineral district, producing coal, iron, zinc, and lead. It was formed after the Great War out of the south-eastern part of Prussian Upper Silesia and the easternmost part of Austrian Silesia (see SILESIA). In the Upper Silesian plebiscite area Poland got the towns of Kattowitz (Polish Katowice) and Königshütte (Kiolewska Huta), both of which voted overwhelmingly for Germany, along with most of the mines; in Teschen-Silesia she got the town of Teschen (Cieszyn), but most of the coalfield went to Czechoslovakia. On account of the mixed population almost complete autonomy has been conceded to Silesia. Area, 1623 sq. m.; pop. (1921) 1,124,967; capital Kattowitz. The territory taken from Prussian Lower Silesia is included in the Polish voivodeship of Posen.

Silesia, PRUSSIAN. See SILESIA, SILESIA (LOWER), SILESIA (UPPER).

Silesia, UPPER (*Oberschlesien*), the south-easternmost province of Prussia and of the German Reich, forms part of the upper basin of the Oder. The Oder itself passes through the western part of the province, and is navigable all the way. Upper Silesia is pre-eminently a mining and manufacturing province, sadly hampered by the cession to Poland of most of its coalfield and nearly all its zinc and lead mines (see SILESIA). Its industries are those connected with iron and steel and other metals, and the manufacture of textiles, glass, pottery, paper, &c. Area, 3746 sq. m.; pop. (1925) 1,377,830; capital Oppeln.

Silex (Lat., 'flint'), a generic name given by some mineralogists to all those minerals of which silica is the principal ingredient. See SILICON, QUARTZ.

Silhet. See SYLHET.

Silhouette, a profile or shadow, outline filled in of a dark colour, the shadows and extreme depths

being sometimes indicated by the heightening effect of gum or some other shining material. This species of design was known among the ancients, and was by them carried to a high degree of perfection, as the monochromes on Etruscan vases amply testify; but the name silhouette is quite modern, dating from about the middle of the 18th century, though the art itself seems to have been practised in England prior to 1745. It

Silhouette of Robert Burns.

was taken from Étienne de Silhouette (1709-67), the French minister of finance for four months in 1759, who, to replenish the treasury, exhausted

by the costly wars with Britain and Prussia, and by excessive prodigalities, inaugurated numerous reforms and the strictest economy of expenditure. His earliest reforms were admirable; his later ones, however, were so capricious, short-sighted, and unsuccessful that he fell utterly from favour, and his name became a byword for injudicious parsimony; any mode or fashion that was plain and cheap was styled *à la Silhouette*; and profiles made by tracing the shadow projected by the light of a candle on a sheet of white paper, the rest of the figure being filled up in black, have continued to bear the name. Profiles cut out of black paper with scissors also receive the name of silhouettes. It should be added that Littré derives the use of the word otherwise: quoting from the *Journal Officiel* of 1869 a statement that one of M. de Silhouette's chief amusements after his fall was making such shadow-portraits, and that his château of Biy-sur-Marne had the walls of several of its rooms adorned with pictures of this sort. M. de Silhouette was at an earlier date secretary and chancellor to the Duke of Orleans, and was one of the three commissioners appointed in 1749 to delimit the frontiers of the French and British possessions in Acadia. He wrote a number of works, and published translations from Bolingbroke, Pope, and Walburton. See Mrs E. N. Jackson, *The History of Silhouettes* (1911); Desmond Coke, *The Art of the Silhouette* (1913).

Silica. See SILICON.

Silicon is one of the non-metallic elements: sym. Si; at. number 14; at. wt. 28.4 (O=16); sp. gr. of crystalline form, 2.49. It may be obtained in three different forms—viz. the *amorphous*, the *graphitoid*, and the *crystalline*. It is amorphous silicon which is obtained by the processes in common use, the other forms being obtained from it.

Amorphous silicon presents the appearance of a dull brown powder, which adheres to the finger, is insoluble in water and in nitric and sulphuric acids, but readily soluble in hydrofluoric acid and in a hot solution of potash. It is a non-conductor of electricity, and when heated in air or oxygen its external surface burns brilliantly, and is converted into silica, which fuses from the extreme heat, and forms a coating over the unburned silicon. *Graphitoid* silicon is obtained by exposing the amorphous variety to an intense heat in a closed platinum crucible. This form of silicon will not take fire when heated in oxygen gas, and resists the solvent action of pure hydrofluoric acid, although it rapidly dissolves in a mixture of nitric and hydrofluoric acids; moreover, it is a conductor of electricity. Deville obtained *crystallised* silicon in regular double six-sided pyramids of a dark steel-gray colour.

Silicon, in a state of combination with oxygen, is the most abundant solid constituent of our globe; in less proportion, is an equally necessary ingredient of the vegetable kingdom; while in the animal kingdom it occurs in mere traces, except in a few special cases. It is never found in nature except in combination with oxygen; but, by a somewhat difficult process, it may be separated as a dark brown powder. It was first isolated by Berzelius in 1823. For our knowledge of the other modifications we are indebted to Wöhler and Deville.

Silicon forms an oxide, the well-known compound silica, represented by the formula SiO_2 . Silica exists both in the crystalline and in the amorphous form. The best examples of the crystalline form are rock-crystal, quartz, chalcedony, flint, sandstone, and quartzose sand. Silica in this form has a specific gravity of about 2.9, and is only

attacked with difficulty by potash or hydrofluoric acid. The amorphous form exists naturally in opal, and is obtained artificially as gelatinous silica, &c.; it differs from the former in its specific gravity, being about 2.2, and in its being rapidly dissolved by potash and by hydrofluoric acid. Pure silica (as it occurs in rock-crystal, for example) is perfectly transparent and colourless, and is sufficiently hard to scratch glass. The heat of the oxyhydrogen blowpipe is required for its fusion, when it melts into a transparent glass, capable of being drawn out into elastic threads. Perfectly pure silica in its amorphous form may be obtained by various chemical processes. If a solution of silicate of potash or soda be treated with hydrochloric acid, the silicic acid separates as a hydrate, and on evaporating this to dryness, and treating it with boiling water, silicic acid remains as an amorphous powder, which, after being washed, dried, and exposed to a red heat, may be regarded as chemically pure. The hydrated silicic acid mentioned in the above experiment is soluble in water, and (more freely) in acids and alkalis. The solubility of hydrated silicic acid in water accounts for the presence of silicic acid in mineral springs and in the geysers of Iceland, as well as for its gradual separation from these waters in the form of petrifications. That silicic acid is a true acid (although a feeble one) is obvious from its uniting with bases, especially those which are capable of undergoing fusion, and forming true salts, known as silicates. These silicates occur abundantly in nature, all the forms of clay, felspar, mica, hornblende, augite, serpentine, &c., being compounds of this description.

Most of the silicates are fusible, the basic silicates fusing more readily than those which are either neutral or contain an excess of acid. Excepting the silicates of the alkalis, no silicates are soluble in water. The anhydrous, neutral, and acid silicates of the earths resist the action of all acids except hydrofluoric.

Silica derives its name from the Latin *silex*, 'flint,' of which it is the essential constituent, and is largely employed in the manufacture of glass, china, and porcelain. For these purposes it is obtained in a finely comminuted state by heating flints or portions of colourless quartz to redness, and plunging them in cold water. The silica splits up into a friable mass, which may be easily ground to a fine powder. The use of silica in giving firmness and rigidity to various parts of the animal organs is exemplified in its free occurrence in the quill-part of the feathers of birds, in the shields of certain infusoria, and in the spicules occurring in sponges; while its similar use in the vegetable kingdom is seen in its more or less abundant presence in the stalks of the grasses, more particularly in the cereals and in the bamboo (where it is especially deposited about the joints, and is known as *Tabasheer*), in the Equisetaceae, &c. Fused silica is now much used in chemical apparatus in place of the more expensive platinum.

Silicon may be made to combine with several other elements besides oxygen, but most of these compounds are of no practical value. With carbon it unites in the electric furnace to form carborundum. Silicon and hydrogen form a hydride of silicon, a colourless and spontaneously inflammable gas. Nitride of silicon is a bluish fibrous body, while sulphide of silicon is a white earthy powder. Silicon unites with the halides. Fluoride of silicon, SiF_4 , is a colourless pungent gas. It is obtained by heating powdered glass with hydrofluoric acid. When a stream of this gas is transmitted through water a reaction takes place, yielding silicofluoric acid, H_2SiF_6 . A saturated solution of this acid

forms a very sour turning liquid, which does not directly attack glass, but if allowed to evaporate on it causes erosion from the fluoride of silicon becoming evaporised, and free hydrofluoric acid being left. A dilute solution is sometimes employed in the laboratory as a precipitant of potash, which it throws down in a transparent gelatinous form. With salts of baryta it gives a white crystalline precipitate. It combines with bases to form salts.

For soluble glass, a silicate of soda or potash, see GLASS, Vol. V. p. 244; and for silicate cotton, see SLAGS.

Siliqua. See FRUIT.

Silistra, or SILISTRIA, a town of Rumania (till 1913 Bulgaria), on the right bank of the Danube, here $1\frac{1}{2}$ mile wide, about 70 miles NW. of Varna. Owing to its strategic position it has for many centuries been a more or less formidable fortress, especially since the 14th century, under the dominion of the Turks. The Roman *Durostorum*, it was captured by the Russians under Sviatoslaff in 867, but was recovered in 971 by the Byzantine emperor, John Zimisces. It has been repeatedly besieged by the Russians. They destroyed the works after capturing it in 1810; but the fortifications were rebuilt more strongly than before, and offered a stout resistance to the Russian attacks in 1828-29. In 1849 it was made a stronghold of the first class, and was rendered almost impregnable by the addition (1853) of twelve detached forts on the south and east. On the outbreak of the Crimean war the Russians laid siege to it with an army of from 60,000 to 80,000 men, but were compelled to retreat after thirty-nine days. In 1877, again, it successfully defied the troops of the tsar. The Congress of Berlin in 1878 decreed that the fortifications should be dismantled; but this was not given effect to. It was besieged by the Rumanians in the second Balkan war (1913), and in the Great War was taken by Mackensen (1916). The people weave cloth, tan leather, and grow vegetables. Pop 12,000.

Silius Italicus, a minor Latin poet, was born in 25 and died in 101 A.D. At an early age he became a prominent forensic orator, was consul the year of Nero's death (69), became a familiar friend of Vitellius, and was afterwards proconsul in Asia. He was a devoted student of Cicero and Virgil, and owned their estates at Tusculum and Naples. In old age, finding himself labouring under an incurable disease, he starved himself to death. His epic poem, *Punica*, in seventeen books and about 14,000 lines, has come down entire, and remains a monument of industry, of patient imitation, not of poetic creation. Scipio and Hannibal are its Achilles and Hector, its Æneas and Turnus; and every episode in his great originals is slavishly reproduced and degraded to a dead level of literary mediocrity.

The poem was discovered by Poggio about 1416, and the *editio princeps* appeared in 1471. Editions are by Ernesti (1791) and Lemaire (1823), and in Postgate's *Corpus Poet. Lat.* (Fasc. iv. 1904).

Silk appears to have been first systematically manufactured by the Chinese, although some claim that the Tussur silk of India was the earliest silk fibre used. The name is derived from the Chinese name of the silkworm *szze, see, or si*, in Korean *sir*, whence the Greek *σίπ*, 'the silkworm'; *σῆπες*, 'the people furnishing silk,' 'the Chinese'; and *σινικόν*, 'silk.' The Latin *sericum* has been traced to the Mongol *sirkeh*; and the *serikoth* of Isaiah xix. 9 has been supposed to be silk. From *sericum* is derived the French *soie*; and etymologically connected with it are the German *Seide*, the Russian *shelk*, the Old English *seole*, the Icelandic *silke*, and the modern

English *silk*. We are informed by Hawae-nan-tze, in a Chinese work called the *Silkworm Classic*, that Se-ling-she, the principal queen of Hwang-te (2640 B.C.), was the first to rear silkworms, and the Emperor Hwang-te was induced to invent robes and garments from this circumstance. The Chinese historians carry back the cultivation of the mulberry and the breeding of silkworms to the mythic period. If they are to be believed, the art of silk-reeling was known in China in the time of Foh-hi, a century before the date usually assigned to the biblical deluge, and Hwang-te's queen did not disdain to share in the labours attending the care of the insect, as well as in those of the loom, the invention of which seems to be attributed to her, and to have raised her to the position of a tutelary genius with special altars of her own. But whatever the precise date of the discovery, it appears there can be no question of the very high antiquity of the knowledge of the worm and its product in China. A series of imperial edicts and voluminous literature of practical treatises testify to the importance of the industry and the care that was taken to foster an art which was considered, according to M. de Rosny, 'best fitted to promote the morality of the people and extinguish pauperism in the empire.' The queen and wives of the nobles through successive generations personally attended to the rearing of the silkworms. That this silk was of the mulberry-fed kind is evident from a further extract from the *Silkworm Classic*, which says that afterwards 'When Yu regulated the waters (2200 B.C.) mention is made, in his work on the tribute, of the land adapted for the mulberry-tree having been supplied with silkworms, from which time the advantage thereof gradually increased.' It is not known whether silk was utilised in India at so early a period as this—probably not; but that India learned the art from China is generally believed, although at what period is not known.

About the middle of the 6th century A.D. the western world received a supply of silkworms' eggs. They were conveyed from China to Constantinople by two Persian monks who had gone to the East as missionaries, and had observed in China the various processes connected with the rearing of silkworms, the nature of the trees on which they fed, and the preparation of the silk. This occurred in the year 552, in the reign of Justinian, who gave every encouragement to the introduction of the valuable insect. The eggs were secretly conveyed from China within a hollow cane; at the proper season they were hatched, and the caterpillars were fed on the leaves of the wild mulberry-tree. The monks continued to superintend at Constantinople the rearing of the insects and the whole process of manufacturing the silk. From this small commencement the myriads of silkworms have sprung which throughout eastern and western Asia have met the demand for silk—a demand that has gone on increasing from that time to the present.

Natural and Life History.—The natural history of every kind of silk may be briefly stated. From a small egg laid by the moth, of whatever species, appears in due season a small larva, or caterpillar, or worm, as it is usually called. This worm, after having lived its day, feeding only on the leaves of certain plants specially suited to its own species, and increasing in size, spins, or rather secretes, a fine silk thread around itself for a covering and protection during the time it lies dormant in the next stage of its existence. As soon as it has secreted all the silk, it changes into a pupa or chrysalis, and remains inside its silken cell until the time for its appearance as an imago or perfect moth, having four scaly wings, with six legs, and

two antennæ, which are larger in the male than in the female. When its hibernation is ended it emits a fluid which softens the end of its cocoon cell, and, by means of its wing-spines and legs, parts the fibres aside until the opening is large enough for it to creep out. After a short time its wings expand and dry, and it enters into a perfect state. It lives only a few days in this phase of existence.—It is in this stage only that the race is perpetuated, the female laying a number of eggs and dying soon afterwards (see the articles INSECTS, CATERPILLAR, CHRYSALIS, COCOON).

There are a number of species of silkworms whose food is the leaves of the mulberry-tree, the principal and most useful of which is the *Bombyx mori*. The following is a list of mulberry-feeders, the various kinds of *Bombyx* alone being domesticated, the others being wild:

Bombyx mori (Linnaeus).—The common silkworm, domesticated in China, Bokhara, Afghanistan, Kashmir, Persia, South Russia, Turkey, Egypt and Algeria, Italy, France, and Spain, in all which countries it produces but one crop annually, spinning the largest cocoon and the best silk of a golden yellow or white.

B. textor (Hutton).—The Boro Poloo of Bengal, domesticated in South China and Bengal; an annual only, producing a white (sometimes yellow) cocoon of a different texture and more glossy than *B. mori*.

B. sinensis (Hutton).—The Sina, Cheena, or small Chinese monthly worm of Bengal, introduced from China, and partially domesticated in Bengal; produces several broods in the year; cocoon white and yellow.

B. crasi (Hutton).—The Nistiri or Madrassee of Bengal, introduced from China, and domesticated in Bengal; yielding seven or eight broods of golden yellow cocoons in the year of larger size than *B. sinensis*.

B. fortunatus (Hutton).—The Desi or Chota Poloo of Bengal; yields several broods annually, spinning the smallest cocoon of a golden yellow colour.

B. aracanensis (Hutton).—The Burmese silkworm, domesticated in Arakan, said to have been introduced from China; yields several broods annually; cocoons larger than the Bengal monthly species.

Theophila huttoni (Westwood).—The wild silkworm of the north-west Himalayas, feeding on the indigenous mulberry in the mountain forests.

T. shervillii (Moore).—The wild silkworm of the south-east Himalayas.

T. bengalensis (Hutton).—The wild silkworm of Lower Bengal, discovered in the neighbourhood of Calcutta, feeding on *Artocarpus Lakoocha*. Found also at Ranchee, in Chota Nagpore.

T. religiosa (Helfer).—The Joree of Assam and Deomooga of Cachar. Feeds also on the ber tree (*Ficus bengalensis*) and the peepul (*F. religiosa*).

T. mandarina (Moore).—The wild silkworm of Chekiang, North China; said to feed on wild mulberry-trees, and on *Quercus serrata*, spinning a white cocoon.

Oenara lactea (Hutton).—Masuri, north-west Himalayas; also feeds on *Ficus Tsjakala*, spinning a small yellow cocoon, yielding several broods during the summer.

O. moorei (Hutton).—Masuri; also feeds on *F. Tsjakala*, as well as on the wild fig, spinning a small white cocoon. It is a multivoltine (see below).

O. diaphana (Moore).—Khasi Hills.

Trilocha varians (Walker).—North and South India.

In Italy and France *B. mori* is cultivated under active government encouragement and oversight, having during centuries of effort become a subject of high national importance. The United States of America and the British colonies are making efforts to introduce the cultivation of *B. mori*; the only hindrance being in the high price of labour for cocoon reeling. *B. mori* is univoltine or annual; but *B. fortunatus* and *B. crasi*, which are confined to Bengal, are multivoltine—i.e. they produce several broods annually. For wild silks not from mulberry feeders, see page 394.

Classification.—The silk-producing Lepidopterous insects are of many species, possessing very marked structural differences, whilst the variety and quiet

beauty of their colours, and in many species their large size, contribute greatly to the charm of studying this branch of natural history. They belong to the order Lepidoptera, sub-order Heterocera or Moths, group Bombycina, and to several of the twenty-seven or more families which compose this group, the most important being the Bombycidae and the Saturniidae. All the Saturniidae are silk-producers, but not all the Bombycidae. Recent researches have resulted in adding many new or previously unknown species to the list of silk-producers, and the known number is now upwards of 400, and the list is by no means complete.

The Bombycidae have a very short and rudimentary proboscis, live for a very brief time in their perfect state, and take little or no food; the body is thick and hairy; the antennae are pectinated. The caterpillars feed on the leaves and other tender parts of trees or other plants; the chrysalises are enclosed in a cocoon of silk, which gives to some of the species a great economical importance. The most important is the Common Silkworm (*Bombyx mori*), cultivated chiefly in China, Japan, Italy, and France. The perfect

Fig. 1.—Common Silkworm (*Bombyx mori*):
a, larva, full grown; b, larva, seripositing; c, cocoon;
d, chrysalis; e, female moth, f, male moth.

moth is about an inch in length, the female rather larger than the male; the wings meeting like the sides of a roof; the colour pale buff with a broad pale brown bar across the upper wings. The females generally die very soon after they have laid their eggs, and the males do not survive much longer. The eggs are numerous, about the size of a pin's head, not attached together, but fastened to the surface on which they are laid by a gummy substance, which, when dry, becomes silky. In Europe they are laid in spring, and are hatched in summer. The caterpillar is at first very small, not more than a quarter of an inch in length, but rapidly increases in size, till, when full grown, it is nearly 3 inches long. It is of a yellowish-gray colour. The head is large. On the upper part of the last joint of the body is a horn-like process. The skin is changed four times during the growth of the caterpillar. Before each change of the skin it becomes lethargic and ceases to eat, whereas at

other times it is very voracious. When the skin is ready to be cast off it bursts at the forepart, and the caterpillar then, by continually writhing its body, without moving from the spot, thrusts it backwards; but silkworms frequently die during the change of skin. A very rapid increase of size takes place whilst the new skin is still soft. The natural food of the silkworm is the leaves of the white mulberry, but it will also feed on the leaves of some other plants, as the black mulberry and the lettuce. When so fed, however, it produces silk of inferior quality. The silk-producing organs are two large glands (*sericteria*) containing a viscid substance; they extend along great part of the body, and terminate in two seripositors in the mouth. These glands become very large when the change to the chrysalis or pupa state is about to take place. When about to spin its cocoon the silkworm ceases to eat, and first produces the loose rough fibre which forms the outer part of the cocoon, and then the more closely disposed and valuable fibre of its interior. In this process the position of the hinder part of the body is little changed, but the head is moved from one point to another; and the cocoon when finished is much shorter than the body, which, however, being bent, is completely enclosed in it. The cocoon is about the size of a pigeon's egg. Each fibre of silk or *bave*, when examined by a microscope, is seen to be double or of two *brins*, being equally derived from the two silk-producing organs of the caterpillar. The *bave* or double thread often exceeds 1100 feet in length. The time of the silkworm's life in the caterpillar state is generally about eight weeks. About five days are occupied in the spinning of the cocoon, after which about two or three weeks elapse before the cocoon bursts and the perfect insect comes forth. The opening of the end of the cocoon by the moth for its escape is, however, injurious to the free and perfect reeling of the silk from the cocoon, and the silkworm rearer prevents this by throwing all the cocoons into hot water or more usually into an oven, called in France *étouffoir*, *séchoir*, heated by hot air or by steam, except those which he intends to keep for breeding. These he selects with care, so that he may have about an equal number of male and female insects, the females being known even in the chrysalis state by their larger size. The cocoons intended for the production of moths are placed on a cloth in a somewhat darkened room, of which the temperature is near, but does not exceed, 72° F.; and the moths, when produced, show no inclination to fly away, but remain on the cloth, lay their eggs, and die there. It is an interesting peculiarity of this valuable species of moth that neither in the caterpillar nor in the winged state does it show that restless disposition which belongs to many others, the caterpillars remaining contentedly in the trays or boxes in which they are placed, feeding on the leaves with which they are there supplied, and at last only seeking a proper place for making their cocoons for their covering and protection. Whilst assuming the chrysalis state small bundles of twigs are placed above the feeding-trays for the worms at their last caterpillar stage to resort to for cocoon building. Owing to this peculiarity or domesticity, it is capable of being reared and managed in a way which would otherwise be impossible.

Rearing of Silkworms.—It is of the first consequence in the production of silk that one of the species of mulberry should be cultivated, and that it should be so favourably situated as to climate that it is in readiness for feeding the worms. The species best adapted is the white mulberry, *Morus alba*. The extreme lateness of season at which the black mulberry produces its leaves prevents its

employment generally, besides which it will not bear the loss of its leaves so well. It is said that in some parts of China the silkworm is easily reared upon the trees in the open air. So little has it a tendency to wander far from the place of its birth, if food be at hand, that it only requires a warm, dry atmosphere to bring it to perfection; but usually, even in China, and in all other countries, it is thought desirable to raise the silkworm in properly arranged buildings, and to supply it with mulberry leaves gathered from day to day. In India, China, and other tropical countries the eggs hatch readily at the proper time by the natural heat; but in southern Europe artificial heat is almost always required; formerly the heat of fermenting dung was found serviceable, and the warmth of the human body was also used, the eggs being carried in little bags in the bosom of the cultivator; but now they are regularly hatched by stove-heat, beginning with a temperature of 64° F., which is gradually increased through ten days to 82°, at which it is maintained until the eggs are hatched. Experience has shown that the operation is facilitated by washing the eggs in the first place with clean water; and some cultivators also wash them in wine, the value of which is very questionable. Washing is found to remove a certain gumminess and other impurities from the eggs which would otherwise impede the hatching. When the silkworms have been regularly developed as above described, it is usual to place above the trays contrivances for the caterpillar to spin within. In feeding the worms care is taken so to distribute the food on the shelves or in the trays that the insects shall not crowd together; and for this reason the most careful cultivators chop the leaves small, and strew them very evenly about. Great care is taken not to let the worms of one hatch mix with those of another, unless of exactly the same age, otherwise the stronger insects would deprive the younger of their food. Many other niceties of attention are required, which altogether render the successful rearing of silkworms a matter of much anxiety and labour.

Diseases.—Silkworms are subject to various diseases. In all about fifteen have been defined, but the most important, which only need mention here, are *Musccardine*, *Pebrine*, *Flacherie*, *Guttine*, and *Grasserie*. *Musccardine* is the result of the growth on the silkworm of a microscopic fungus named *Botrytis bassiana*. The spores of this minute fungus are not larger than the two millimetres of a millimetre. They are carried by the air, and falling on the mulberry leaves or on the worms cause the disease. Worms affected with muscardine die before arriving at the moth. In the magnaneries where the disease is present or is suspected they are daily fumigated with sulphurous acid gas (fumes of sulphur), which kills the spores, but does not hurt the worm. *Pebrine* is the most important disease. Worms affected with it are without difficulty detected; amongst other well-known signs by the appearance of blackish spots on the skin. This disease is the consequence of a corpuscle or bacillus, which, once having entered the worm, multiplies rapidly. The interior of the body of a moth is often found to be quite full of corpuscles. *Pebrine* is found in all the life-stages of the insect. Prevention is the remedy laid down by Pasteur, and in all well-managed rearing-houses the microscope is employed to examine the eggs, when those found to be pebrinised are rejected. This method, combined with greater cleanliness, desiccation, and fumigations of chlorine, has been so successfully used since 1865 that pebrine has nearly disappeared in a number of localities in France and Italy where previously sericulture had become almost extinct, and it now only exists where these precautions

are not sufficiently observed. *Flacherie* is a deadly and contagious disease, and is the result of bacterial growth of a vibronic nature. The worms are attacked in their last stage, having arrived at their full size; they languish, die, and decompose rapidly, a whole chamber sometimes perishing in a day. Pasteur has fully studied this disease, and has pointed out preventive remedies. It is generally the result of other diseases and the want of proper precaution, especially as to the careful conservation of the eggs from the laying of them to the time they are hatched. *Guttine* is a disease of the same character, and is probably only a modification of flacherie. *Grasserie* is of less importance than the other diseases; but it is interesting and not very well understood. A few worms will frequently be found in the midst of healthy ones, which are evidently ailing, crawling slowly, with a glossy skin, becoming thinner and longer. In the yellow races the colour becomes bright, and in the white races an unhealthy milky-white appearance, and through the skin there exudes a dirty liquid which under the microscope is seen to contain a multitude of many-sided globules, probably albuminous. A cold, stagnant, or damp atmosphere, or a too crowded chamber, favours the commencement of this disease, which is neither hereditary nor contagious.

Preparation of Silk.—When the cocoons are completed, which is known by the absence of any sound within, they are carefully sorted, and a certain number are kept for breeding. The sexes are readily known by the difference of shape as well as of size. The French growers sort them into several varieties; those which are less compact, or in which the worm has died—a fact known by external indications—being separated from the good ones. When the sorting is finished, the cocoons are placed in an oven with a gentle heat, which kills the enclosed chrysalis—otherwise they would all become perforated by the insect eating through; they are then prepared for winding by first removing the flossy covering, which is often somewhat hard and compact. The cocoons are placed in basins of water, kept warm by charcoal fires, or in the larger establishments by steam. This softens the natural gum which coats the silk, and loosens the various coils of silk adhering together in the cocoon. The operator then takes a small battage brush made of twigs and stirs them about in the water. This catches the outside portions of the cocoon, from which the reelable thread is gradually unwound. From three to five of these ends are taken and united into one thread, which is passed through a polished metal or glass eye in the reeling-machine. In large filatures or silk establishments complex machinery is used for winding; but reeling apparatus of greater simplicity is used by the Chinese, East Indians, and others. In all cases, however, the principle is the same. The plan most generally adopted in Italy is shown by fig. 2.

Great care and skill are required in reeling silk from the cocoons, because, although the reeler starts with four or five or six cocoons, not only are their individual threads apt to break, but they are not all of the same length, so that one will run out before the others. These matters are carefully watched, and, as often as a thread breaks or a cocoon runs out, another thread is joined on and is made to adhere to the compound thread on the reel by its natural gumminess. Each cocoon generally yields about 300 yards of thread, so that it takes 1200, 1500, or 1800 yards to make 300 yards of the filament of raw silk, by which name the reeled silk is always known. The raw silk is made up into hanks of various sizes. That from China and Japan is tied in packages of six hanks

each, technically called books, and sometimes the ends of these books are covered with silken caps very curiously formed out of unreeled cocoons macerated and felted into a thin material, so managed as to form a filmy cap sufficiently large to cover a man's head. Formerly all raw silk required to be made into compound and twisted threads was termed thrown silk, but at the present time much is woven in the raw state and afterwards dyed in the piece. The raw silk is used for the warp, and spun silk and cotton for the weft, of the cheaper kinds of silks, such as foulards and some satins, made in large quantities in Lyons.

When the silk has to be thrown into organzine or tram, the raw silk is put into warm soap and

water to soften the gum, so as to make the hanks wind more easily. The hanks are placed on large skeleton reels called swifts (A, B, fig. 2), so adjusted that they will hold the hanks tightly. B, the

Fig. 2.

edge view, shows that the spokes, *a, a*, are in pairs. They are made of thin pieces of lance-wood, and each pair are rather nearer together at the axle than at the circumference, where they are connected together by a small band of cord, *b, b*. These bands are so tied that they will slip down easily to admit of the hanks being placed; then, by pushing the cords upwards, the hank can

be stretched to its fullest extent. This is necessary to compensate for the varying lengths of the hanks received from the different countries.

When the swifts are set in motion the silk is carried from the hanks to bobbins, upon which it is wound for the convenience of further operations. The bobbins are then taken from the winding to the cleaning machine, when they are placed on fixed spindles, so that they will turn with the slightest pull; and the thread is

Fig. 3.

passed through a small apparatus attached to the machine, which is specially called the cleaner, and consists essentially of two polished smooth-edged blades of metal (*a, a*, fig. 3) attached to a part of the frame of the machine, *b*. They are held together by the screw, *c*, and are slightly opened or closed by the other screw, *d*, so that the thread can be put between them down to the small orifice, *e*, and then, by tightening the screw, preventing its return after passing through this small hole, which is the gauge of the thread, and which removes any irregularities or adherent dirt. The silk next passes over a glass or metal rod, and then through another small hole, much larger than that of the cleaner, and usually made of glass, on to the bobbin, upon which it is wound by the action of the machine. The next process is twisting the cleaned thread, by which it becomes better adapted for being combined with other threads. Doubling is the next process, and this consists in running off a number of bobbins of twisted silk on to one bobbin of a larger size, which is put into the throwing machine, when the ends of the doubled silk are passed through a smooth hole on to a large reel, which reel winds it into hanks, but twisting the threads into a fine cord as it goes from the bobbins to the reel. After this the hanks have to be again wound on reels and bobbins for the weaver, the

former for the warp and the latter for the weft. If it has been wound, cleaned, and thrown it is called thrown-singles; if wound, cleaned, doubled, and thrown, it is called tram, and is used for the richer silks and velvets, but only for the weft or shute; and if wound, cleaned, spun, doubled, and thrown, it is called organzine, and is used for the warps of fabrics.

'Waste' or Spun Silk.—Before winding the cocoons a flossy portion has to be removed, and then, in reeling, throwing, and other processes, a certain quantity of 'waste' is made, known as 'throwsters' waste. To these have to be added the fibres resulting from soft, damaged, misshapen, and pieced cocoons, all of which constitute a valuable species of by-product. 'Knubbs' is the term applied to cocoons drawn out into a long ribbon-like mass, and 'Punjam Books' to rough-looking hanks of filament which accrue in the winding of a large number of cocoons. Further, the difficulty experienced in the winding of Tussur cocoons causes a considerable portion of them to be employed in the preparation of spun silk.

As early as 1671 an invention was patented by Edmond Blond, a silk manufacturer, for the treatment of such waste by carding and roving; and other early attempts followed on this principle. But a practical method of working the substance into a yarn for commercial use was not designed till the middle of the 19th century. It appears to have been initiated in the West Riding of Yorkshire, where the machinery is still constructed for different parts of the world, and where this class of silk-spinning remains an important branch of textile industry. By the modern system, after degumming by either the 'boiling' process (English practice) or by the Schapping or steeping process (Continental practice), the 'waste' is (1) dressed, prepared into 'stricks' of straightened fibre; (2) combed; and (3) drawn and spun.

Centres of Manufacture.—The following silk centres represent the present and past localities of British silk manufacture: London (Spitalfields), Derby, Coventry, Sherborne (Dorsetshire), Sudbury, Glemsford and Haverhill (Suffolk), Braintree, Yarmouth, Bungay, Leicester, Nottingham, Norwich, Macclesfield, Leek, Congleton, city and district of Manchester, Rochdale, Bradford, Halifax, city and district of Glasgow, city and district of Dublin, Tideswell (Derbyshire). Leek is justly celebrated for its manufactures of sewing and embroidery silks, and has become one of the principal centres of silk-dyeing in England. It is noted for the production of a special 'raven black,' nowhere else produced, and so called from its resemblance to the bluish-black plumage of a raven's wing. The value of this shade is said to be partly owing to the peculiar quality of the water used in dyeing. Silk is also dyed in London, Glasgow, Macclesfield, Coventry, Middleton, and other places, but to a much diminished extent.

Statistics.—About 100 lb. of cocoons are raised from 1 oz. of eggs, and 12 to 14 lb. of cocoons yield 1 lb. of raw silk; but the quantity is variable, and depends on silkworm study, selection of eggs, and in crossing the numerous varieties. As far as can be ascertained, the total quantity of raw silk annually produced in the world is upwards of 22 millions of pounds. China furnishes 38·53 per cent.; Italy, 29·65 per cent.; Japan, 12 per cent.; France, 7·52 per cent.; the Levant, 6·21 per cent.; India, 3·32 per cent.

Of silk manufacturing countries France is the principal. France itself produces about one-eighth of the raw silk consumed, the rest being imported from Italy and Asiatic countries. Of the world's manufactured silk France produces about two-fifths.

American Silk Industry.—The history of silk production in America dates from 1530, when the first mulberry-trees and silkworms were imported into Mexico. But by 1600 the industry had died out there; and a like fate overtook it in Virginia before the end of the next century, and practically everywhere by the beginning of the 19th century, although it had been vigorously encouraged by England, flatures established, and Georgia alone in one year had sent home nearly 2000 lb. of raw silk. About 1825 a powerful effort was made to revive the industry in the United States; silk societies were established, and manuals of silk-culture, such as J. H. Cobb's, printed and distributed by state legislatures and by congress. But success was prevented by a craze for speculation in Chinese mulberry-trees, which ended in widespread ruin in 1839. Since then silk-culture has never flourished in America. It was taken up with eagerness in California in 1854, but quickly dwindled and died; there is a state board of silk-culture in San Francisco, but it has not succeeded in arousing much interest in it. At Philadelphia a Woman's Silk-culture Association was founded in 1876, so far with the same result; nor has commercial success encouraged the attempts of the Agricultural Department, which established a flature at Washington in 1886 for reeling silk from American cocoons, and has distributed eggs of large Milanese silkworms. But if silk-culture has failed so far to engage American attention and capital, the reverse has been the case with the silk manufacture. This began in New England early in the 18th century, and steam-power for the manufacture of sewing-silk was introduced in 1810, improved machinery quickly following, until before the Civil War a great trade had grown up in twist, dress-trimmings, ribbons, and woven silk goods. Laces were manufactured at Brooklyn in 1871, and since 1876 silk handkerchiefs, tapestry, and velvets, besides dress-silks of all sorts, have been manufactured in steadily increasing quantities and excellent qualities. The most famous seat of the American silk manufacture is Paterson (q.v.).

Wild Silks.—This is a generic term generally signifying those silks used in commerce, and those not at present utilised, other than silk of the mulberry-feeding worms; but it relates almost entirely to the Saturniidae, whose fibres are more or less flat; it necessarily includes a few species which are subject to more or less of domestication, such as the Eria and Muga of Assam. Most of the principal wild silkworms are Asiatic. The best known are those of India. There are a few species in North America, one or two of which have received some attention. South America and the West Indies contain many others, and are almost unworked fields. The following list includes all the principal wild silks:

Atlas and Eria Group.—*Attacus atlas*, *A. silhetica*, *A. edwardsia*, *A. cynthia*, *A. ricini*, *A. canningi*, *A. lunula*, *A. obscurus*, *A. guerini*.

Actias Group.—*Actias selene*, *A. sinensis*, *A. leto*, *A. manas*, *A. ignescens*.

Tussur and Muga Group.—*Antheraea mylitta*, *A. pernyi*, *A. andamana*, *A. meankooria*, *A. frithii*, *A. nebulosa*, *A. helferi*, *A. perroteti*, *A. assama*, *A. roylei*.

Miscellaneous Group.—*Salassa lola*, *Rinaca zuleika*, *Rhodia newara*, *Caligula thibeta*, *C. simla*, *C. cachara*, *Neoris huttoni*, *N. shadulla*, *N. stoliczkan*, *Saturnia cidosa*, *S. grotei*, *S. hindia*, *S. anna*, *Lopha katinka*, *L. sikkima*, *L. sivalica*, *L. miranda*, *Orcula trifenestrata*, *C. drepanoides*, *Antheraea confuci*, *A. yama-mai*, *Saturnia pyretorum*, *Theophila mandarina*.

Of these a few species only need be noticed here. *Antheraea yama-mai* is a Japanese species, which feeds on the leaves of the oak. It is peculiar to

Japan, and has long been held in high estimation there, more so formerly than now. At one period its silk was solely reserved for the use of royalty, and the penalty of death is said to have been inflicted upon any person found using it or taking the eggs. At the present time it is woven along with the ordinary silk of commerce in patterns, giving the separate effects of each silk. The Eria silk is the product of the Eri or Arindi worm of Assam (*Attacus ricini*). It is largely cultivated in that part of India, and is handspun and woven by the natives in garments, rough, but so durable that mothers are said to leave them to their daughters. The cocoon is soft and not compact; it has hitherto been found impossible to unwind it in a continuous thread, and in consequence of this difficulty it is rudely spun by hand like flax. It would be largely employed in Europe for machine-spinning if it could be cultivated and exported in quantity. Its excellences for this process of manufacture are well known. The worm chiefly feeds on the *Ricinus communis*, or castor-oil plant. *Attacus cynthia* is a species closely allied to *Attacus ricini*. It comes originally from China, and feeds on the Ailanto (q.v.) tree. Its cocoons were first received in Europe in November 1856, and hatched out the following year, and towards the middle of May 1857 the first living specimen of *Attacus cynthia* was born in Europe. These cocoons were sent by Abbé Fantoni, a Piedmontese missionary, from the province of Shan-tung, to some friends at Tuin. This species was first introduced into England in 1859, and reared by F. Moore of the East India Museum. The larvae, feeding on the castor-oil plant, and hatched from eggs sent by Guérin Méneville, were exhibited by Moore before the Entomological Society of London in October 1859. Afterwards Lady Dorothy Nevill cultivated that species extensively, and planted in her park in the

Fig. 4.—*Ailanthus* Silkworm (*Attacus cynthia*), reduced, showing Cocoon attached to a leaf.

south of England a number of Ailanto trees. Dr Wallace also wrote on this silkworm, and considerable efforts have been made in France and in England to domesticate it, but without success. The *Attacus atlas* is found over India. It is the largest known moth, being often 10 inches in expanse of wing. The cocoon is large, but the fibre is coarse; it has not hitherto been used in the reeled state, but it is utilised in the

Nepal Terai by the Mechi people, in the form of rudely made cloths. The warp and weft are hand-spun yarns of long staple. The *Antheraea assama* or Muga silk is confined to Assam, and is largely cultivated for native purposes. A little is exported to Dacca and Calcutta for embroidery purposes. Could the natives be induced to cultivate it on a commercial scale for exportation it would have a widely extended use, for it is a silk that could easily be utilised for many European purposes.

The last two silks are the principal wild ones; they may from their similarity be classed as one, and are known under the name of Tussur silk—a name said to be derived from *tusara*, a weaver's shuttle. The species known as *Antheraea pernyi* is a native of China; the worm feeds on the leaves

of the oak. It is very largely cultivated for export to Europe. That known as *Antheraea mylitta* is the principal species, and is exclusively Indian, being found over all parts of the country, particularly in Bengal. The Tussur silkworm when fully grown is very large and beautiful. It is about $5\frac{1}{2}$ inches long. Its cocoon is large and compact; the silk is of a deep fawn colour, which has to be resolved before any delicate shades of colour can be dyed upon it. The rapidly extended utilisation of this silk is very wonderful. About 1871 its European use was almost confined to the wearing of native-made cloths in the undyed state, and the consumption was extremely small; but in consequence of improvement in the bleaching and dyeing of this silk, at first effected by the original writer of this article (Sir Thomas Wardle), as well as his suggested utilisation, its importation has now become of serious import. The fibre is well adapted for pile fabrics, and very large quantities are used in Yorkshire for the manufacture of seal cloths, a fabric resembling sealskin. France has taken up the utilisation of this silk for trimming and upholstery purposes. The fibre of Tussur silk is flat and thick.

A fabric closely resembling silk is now manufactured from wood reduced to a glutinous, transparent pulp. See SILK (ARTIFICIAL).

Seillon; *Coupe des Velours*, by E. Gand.

SILK, ARTIFICIAL, is the name usually employed to designate a number of artificial textile fibres which have been brought into commercial use during the 20th century; but any claim they may have to this title is mainly due to their high silky lustre, and also, perhaps, to the fact that they are formed by the solidification of fine streams of liquid in a somewhat similar manner to real silk. The first suggestion for the manufacture of a fibre to imitate real silk appears to have been due to the French scientist Réaumur in 1734, but nothing seems to have been done for over a century. In 1855 Andemars of Lausanne patented a very primitive process for making fibres from Collodion (q.v.), and during the ensuing thirty years considerable progress was made in the preparation of artificial fibres, but mainly with the object of preparing carbon filaments for the incandescent electric lamps then in use and not as textile fibres.

The real founder of the artificial-silk industry was a Frenchman, Comte H. de Chardonnet (1839–1924), who took out a patent in 1884 and, after overcoming great difficulties, was able to place the manufacture on a commercial basis about 1891. Many substances have been tried as a basis for artificial silk, but all the successful methods start either from cotton or from some other Cellulose (q.v.) material such as wood-pulp. Speaking generally, the methods of manufacture are similar in all cases. A viscous solution of cellulose, or of some cellulose derivative in a suitable solvent, is forced under pressure through fine jets or openings (spinnerets) either into the air, if the solvent be readily volatile, or else into some suitable liquid which will precipitate the cellulose substance from its

solution. In either case, the threads of viscous liquid issuing from the spinnerets are rapidly coagulated into fine solid filaments, a number of which are twisted together to form a continuous thread. The product has then to undergo a number of chemical and other treatments according to the particular process being employed.

The artificial silks at present on the market may be divided into four main groups: (1) Nitro silks; (2) Cuprammonium silks; (3) Viscose silks; (4) Acetyl silks.

(1) *Nitro silks*, sometimes called Chardonnet silks (from their inventor) or Collodion silks, are made by treating cotton with a mixture of nitric and sulphuric acids and dissolving the cellulose nitrate formed in a mixture of alcohol and ether to form a viscous solution of collodion. When this is squirted into the air the solvent evaporates and a silky cellulose nitrate fibre is obtained. This is very inflammable and is treated with chemicals, which convert it into almost pure cellulose no more inflammable than cotton. This was the first process used on the large scale, but is complicated, and, although it is still used, has been largely replaced by cheaper methods. (2) *Cuprammonium silks* are also known as 'Glanzstoff.' This method is largely due to Pauly (1892). Cotton or wood-pulp is converted into a slimy solution by treatment with copper hydroxide and ammonia, and is 'spun' by squirting into an acid or alkaline bath, which precipitates an almost pure cellulose fibre. This method is still used to a fairly large extent.

(3) *Viscose silks*.—The substance viscose itself was first made by Cross, Bevan, and Beadle, 1896. Cotton or wood-pulp is treated with caustic-soda solution and then with carbon disulphide, the solution of viscose obtained is squirted into an acid bath, and after further treatment yields an almost pure cellulose fibre. (4) *Acetyl silks*.—The best-known variety of these is 'Celanese.' Cotton is converted into cellulose acetate by chemical treatment and the product dissolved in acetone. It can be spun in the air as the acetone evaporates, leaving a thread of cellulose acetate, which is the final product, thus differing from the previously mentioned varieties, which are all practically pure cellulose fibres. This variety has quite different dyeing properties to the other textile fibres, which renders it specially valuable for use in combination with the other fibres, which can be then dyed to give two-colour effects.

When cotton is used as a basis the short fibres separated in the cotton ginning and known as 'linters' are employed for cheapness. Artificial-silk yarns as they come into the market consist of a number of single filaments twisted together. These single filaments have been 'spun' as fine as the thread spun by the silkworm itself ($1\frac{1}{2}$ denier), but are usually much coarser. A 150-denier yarn might consist of 18 filaments, each about 8 deniers. The greater the number of filaments in a yarn of a given size, the softer is the feel of the material and the greater its 'covering power.' Coarse filaments are very stiff. Besides yarns varying from 40 to 4000 deniers, some very coarse single filament material is produced for use in hat making, &c.

Staple Fibre or *Fibro* is made by cutting the continuous filaments into short lengths, and is chiefly used for blending with wool or cotton and spinning into mixed yarns. The main defect of artificial silk is its low strength, which is only about a quarter to a half that of real silk when dry, and still less when wet, and also its low resistance to friction. It is deficient in elasticity, and owing to the stiffness and smoothness of the fibres it gives rise to difficulties in weaving and knitting. On the other hand it far surpasses real

silk in the brilliancy of its lustre, and is a fairly durable material if reasonable care be taken in its treatment. Owing to its great lustre it rapidly replaced real silk for braids and trimmings, but from the first its main use has been for knitted goods of all kinds—jumpers, dresses, hosiery, &c.; increasing amounts are employed in weaving such materials as curtains, furnishing materials, damasks, crepe de chine, satins, linings, &c. It is often woven along with wool or cotton, which not only gives a stronger material but also one with more warmth-giving properties; artificial silk alone, owing to its structure, being rather a cold material. It is also much used for the ornamentation of cotton materials for which real silk would often be too expensive.

It is impossible to obtain reliable figures as to the annual production of artificial silk but, in 1926, it was estimated at from 100,000 to 120,000 tons, of which probably 80 per cent. was manufactured by the viscose method. The price in that year was about 6s. to 7s. per pound for a good quality yarn, or about one quarter that of real silk. The largest producers at that date were the U.S.A., followed by Italy, the United Kingdom, Germany, and France, in the order given. Attempts are being made to substitute the name 'Rayon' for artificial silk, but their success appears very doubtful.

Silk, VEGETABLE. See SILK-COTTON.

Silk-cotton. Under this name various silky fibres are from time to time brought from tropical countries to Europe; they are all of the same general character, and are chiefly produced by the trees composing the genus *Bombax* and other genera included in the family *Bombacaceæ* (q.v.). These trees are natives of the tropical parts of Asia, Africa, Australia, and America. The fibre fills their large woody capsules, enveloping the seeds contained in them, and is produced in great abundance, but is too short, too smooth, and too soft to be spun into yarn by machinery. Silk-cotton is, however, used for stuffing pillows, mattresses, sofas, &c. to a limited extent in England, but more largely in Holland, where a long-stapled variety is obtained from Java. One of the best-known silk-cotton trees is *Bombax malabaricum*, a very large soft-wooded tree growing in India, Burma, Java, and North Australia. Its fibre is called *simul*. Another of these trees is *Eriodendron anfractuosum*, which is found in tropical countries of both hemispheres, and which yields the fibre known as *kapok*, used for stuffing life-jackets, quilts, mattresses, &c. Kapok oil is used in the manufacture of soap and margarine. *Cochlospermum gossypium*, a small Indian tree, also yields a silk-cotton. A beautiful fibre of this kind is obtained in the West Indies from *Ochroma lagopus*. *Vegetable silk*, which, like silk-cotton, is only suitable for stuffing, is the covering of the seeds of *Chorisia speciosa*, a Brazilian tree.

Silk-cotton-grass, or SILK-GRASS, a name given to various species of the West Indian biome-laceous genus *Karatas* or *Nidularium*, which yield fibres.

Silk-tail, the Chatterer or Bohemian Wax-wing. See WAX-WING.

Silk-weed. See ASCLEPIAS, FIBROUS SUBSTANCES.

Silkworm Gut, a material used by anglers for dressing the hook-end of the fishing-line. It consists of the drawn-out glands of the silkworm at the time it is about to spin its cocoon and when these glands are fully distended. The worms are immersed for twelve or fourteen hours in strong vinegar, and then taken separately, and pulled

asunder. The skilled operator knows by the strength of the silk-gut if the soaking in vinegar has been sufficient, and if so he lays hold of the ends of the two silk-glands and draws them out gently to the proper length—and so the gut is formed. He then stretches a number of these lengths separately across a board, fixing them at each side or end by slits or pins, after which they are exposed to the sun to dry. Silkworm gut is a very strong material. It is prepared in Italy and Spain.

Sill, or INTRUSIVE SHEET. See IGNEOUS ROCKS.

Sillery, a village in the French department of Marne, near Reims, famous for its Champagne (q.v.).

Silliman, BENJAMIN, American physicist, was born at North Stratford (now Trumbull), Connecticut, August 8, 1779. His father was a colonial judge, and a brigadier-general in the war of independence. He graduated at Yale in 1796, was appointed a tutor in 1799, and was admitted to the bar in 1802, but soon after received from the college the appointment of professor of Chemistry, and proceeded first to study this subject, attending lectures on chemistry for three years at Philadelphia, and in 1805-6 at Edinburgh (on geology also) and London. His chair he filled till 1853, and for two years longer lectured on geology. In the course of many experiments in 1822 he first established the fact of the transfer of particles of carbon from the positive to the negative pole of the voltaic battery. From 1808 he delivered popular lectures on chemistry and geology in many parts of the country, and interested in these subjects many who afterwards became among the foremost of American scientists. In 1840 Professor Silliman was elected the first president of the American Association of Geologists and Naturalists—since grown into the American Association for the Advancement of Science. In 1818 he founded the *American Journal of Science*, better known as *Silliman's Journal*, of which he was for twenty years the sole and for eight more the principal editor. In 1830 he published a textbook on chemistry; he edited several editions of Bakewell's *Geology* and of Henry's *Chemistry*; and in 1853 he published a *Narrative of a Visit to Europe in 1851* (his *Journals of Travels in England, Holland, and Scotland* had appeared as early as 1810). He died 24th November 1864, at New Haven, where a bronze statue was erected in 1884 in the college grounds. See the Life by G. P. Fisher (1866).—His son, Benjamin (1816-85), assisted his father from 1837, in 1847 founded the Yale (since 1860 the 'Sheffield') School of Science, and was its professor of Chemistry till 1869, except in 1849-54, when he held a chair at Louisville. He was professor of Chemistry at Yale from 1854—in the college till 1870, in the medical department till his death. His researches were chiefly in applied chemistry and in mineralogy. From 1845 to 1885 he was co-editor of the *Journal of Science*, and he published very popular manuals of chemistry and of physics, and a volume on *American Contributions to Chemistry* (1875).

Silloth, a seaport and watering-place of Cumberland, on the Solway Firth, 20 miles W. of Carlisle. Prior to the opening of the railway in 1856 it was a mere hamlet, but it is now of growing importance, with good docks opened in 1857-85. Silloth, which commands a fine view, is much resorted to for sea-bathing, the climate being mild and salubrious, and considered highly favourable for those affected with pulmonary complaints. The mean annual temperature is 49° 1', the same as that of Worthing, and only 1° below that of Torquay. It forms a ward of Holme Cultram urban district.

Silo. See **SILAGE**.

Siloam. See **JERUSALEM**, **INSCRIPTIONS**, **HEBREW LANGUAGE**.

Silphium, a gum-resin got from an unidentified umbelliferous plant, perhaps a *Thapsia*, imported by the ancient Greeks from Cyrenaica (q.v.). The juice was used in food and medicine. The name has been given to a genus of *Compositæ* found in the eastern United States. *S. laciniatum*, in exposed places, is a compass-plant, avoiding the mid-day sun by turning its leaf-edges north and south.

Sil'ures, an ancient people inhabiting the south-east of South Wales and the adjoining English area—Glamorgan, Brecknock, Monmouth, Radnor, Hereford. They were a dark and curly-haired race, and were probably of a non-Aryan stock—Iberian or Euskarian—though ultimately Celticised in language and manners. Less civilised than their British neighbours, they were more war-like, and offered fierce resistance to Ostorius Scapula and other Roman invaders. See **WALES**, **BASQUES**, **CELTS**.

Silurian System, a name given by Murchison in 1835 from the Silures (q.v.) in South Wales, where this system is well developed. The sedimentary strata consist principally of grits, slates, dark shales, flagstones, sandstones, and conglomerates, and interbedded with these occur occasional calcareous bands, and more or less lenticular beds of limestone. The following table gives the succession of the Silurian system of Britain:

UPPER SILURIAN....	{ Ludlow Group. Wenlock Group. Llandovery Group.
LOWER SILURIAN OR ORDOVICIAN	{ Bala and Caradoc Group. Llandello Group. Arenig Group.

The strata attain a thickness of more than 20,000 feet, and have a wide distribution. In Wales the basement beds rest conformably on the upper members of the Cambrian system, while a well-marked unconformity separates the Lower from the Upper Silurian. Silurian rocks are exposed at the surface in many of our upland areas: thus, they form a large part of the high grounds of Wales, Westmorland, and Cumberland, and the major portion of the Southern Uplands of Scotland; they may occur in a metamorphosed state in the Highlands. In the hilly parts of Ireland they are also well developed at the surface; nor can there be much doubt that the same strata, buried under younger systems, extend throughout the larger part of the British Islands. The deposition of the Lower Silurian was marked by the appearance of considerable volcanoes in Wales, Westmorland, Ayrshire, and the south-east of Ireland.

On the continent of Europe Silurian strata have an extensive development. They occupy large tracts in Scandinavia and the basin of the Baltic, and probably continue eastwards under the great plains of northern Russia, for they crop up along the flanks of the Ural Mountains. In middle and southern Europe they rise again and again to the surface in mountain-regions, from which it may be inferred that they underlie vast areas in the surrounding low grounds. In North America Silurian rocks extend westwards from the mouth of the St Lawrence by the great lakes into the far north-west, and south-west by the Alleghanies into Alabama. As more or less isolated areas rise to the surface in the interior of the continent, it is probable that Silurian strata, concealed under younger formations, extend throughout the interior continental basin; and they reappear in the Rocky Mountains. The system has been recognised as entering into the formation of the Cordilleras of South America. Silurian strata have

also been detected in the Himalayas and other parts of Asia, in Australia, and New Zealand.

The Silurian rocks which occur in mountainous areas are usually much indurated and dip at high angles, being frequently much contorted and dislocated. In regions of intense folding, as in Norway, they have even been subjected to such disturbance that they have over wide areas acquired a more or less schistose or foliated character. In other low-lying regions, however, as in Russia, the strata are not indurated, and occur in horizontal or gently inclined positions.

Life of the Period.—Plant-remains consist almost exclusively of seaweeds, only a few traces of land-plants having been met with. These indicate a cryptogamic flora—ferns and lycopodiaceous trees. The lower forms of animal life were represented chiefly by sponges (*Amphispongia*, *Astylospongia*, &c.). Amongst the *Cœlenterata* were numerous forms of graptolites and corals. The former are eminently characteristic of the Silurian, and abound in certain thin bands of black shale. Those with two rows of cells are mostly confined to the Lower Silurian, while the single-rowed graptolites are upon the whole most common in the Upper Silurian. Corals abounded—certain limestones appearing to be almost wholly made up of their remains. Some common or characteristic rugose forms were *Omphyma*, *Zaphrentis*, *Cyathophyllum*, &c. Prominent tabulate forms were *Halysites*, *Favosites*, &c. The living *Alecyonarian* corals (*Heliopora*) were represented by *Heliolites*. Crinoids or sea-lilies were very numerous—their jointed stems and arms entering largely into the composition of many of the limestones. Cystideans, which attained their maximum development in Silurian times, star-fishes, and brittle-stars appear to have been less abundant. Annelid-tracks are common on the surfaces of beds, and the filled-up burrows of sea-worms frequently occur. Now and again jaws of annelids are likewise met with, and occasionally their tubular cases (*Serpulites*, *Spirorbis*) are seen attached to shells, corals, &c. Among the most characteristic Silurian fossils were the Trilobites, which made their first appearance in Cambrian seas and reached their greatest development in the Silurian age. They lived on in much diminished numbers through the Devonian and Carboniferous periods, and became finally extinct in Permian times. Some of the more widely distributed Silurian forms are *Ogygia*, *Trinucleus*, *Asaphus*, *Ilænus*, *Phacops*, *Calymene*, &c. Other remarkable Arthropods were the *Eurypterids* (an extinct order allied to the existing king-crabs). One of these (*Pterygotus*) was seven or eight feet in length. Ostracods (*Beyrichia*) and Phyllopods (*Ceratiocaris*) likewise occur in Silurian rocks. Here also we meet with the first scorpion (*Palæophonus*) and the earliest insect (*Palæoblattina*, a form of cockroach). Various lace-corals (*Fenestella*) and other Polyzoa occur, but by far the most abundant forms amongst Molluscs were the Brachiopods. Characteristic types are *Discina*, *Orthis*, *Leptæna*, *Pentamerus*, *Rhynchonella*, *Strophomena*. Lamellibranchs were much less numerous—*Modiolopsis*, *Ctenodonta*, and *Ortho-* nots are examples. Amongst Gasteropods the more common genera are *Euomphalus*, *Bellerophon*, *Holopella*, *Murchisonia*, and *Pleurotomaria*. The Cephalopods are well represented by straight and coiled chambered cells: amongst the former is *Orthoceras*, many species of which are known; the latter show such types as *Cyrtoceras*, *Lituites*, *Phragmoceras*, *Litoceras*, &c. Vertebrates make their earliest known appearance in the Upper Silurian. They are represented chiefly by Ostracoderms, the most remarkable being the small shark-like fishes (*Birkenia*, *Lanarkia*, &c.) discovered by the Geological Survey in the Pentland Hills and Lanarkshire.

Physical Conditions.—The Silurian strata appear to have been deposited chiefly in shallow seas, which here and there, however, may have been moderately deep. No certain indications of true oceanic conditions have yet been met with. During the formation of the Lower Silurian strata the entire area of the British Islands, with the exception, perhaps, of some of the Archæan tracts of the north-west, appears to have been under water. At this time active volcanoes, forming groups of islets, were scattered over the area of what is now North and South Wales, the south-east of Ireland, and southern Ayrshire. Considerable earth-movements affected the British area at the close of the Lower Silurian period—the bed of the sea being here and there elevated, so that islands of considerable size came into existence at the beginning of the Upper Silurian period. Eventually, however, a movement of depression supervened, and the islands referred to were submerged and gradually buried under the sedimentary accumulations of the Upper Silurian sea. Judging from the geographical distribution of the Silurian strata, we are led to conclude that enormous areas of what are now our continents were during the accumulation of those rocks overflowed by shallow seas. The main land-masses of the period seem to have been grouped chiefly in boreal regions and were composed essentially of Archæan rocks. In Europe and North America alike the old land-surface lay towards the north, but the great continental ridges may have risen here and there to the surface in other places so as to form groups of islands, as in Bavaria and Bohemia in Europe, and in the region of the Colorado and Park ranges in America.

The temperature of the seas was such as to allow of the migration of closely allied and apparently identical species of molluscs, crustaceans, &c. over vast regions. In arctic lands fossils occur which are met with likewise in the Silurian rocks of Wales; more than this, many Silurian species were truly cosmopolitan, ranging from the extreme north across the equator to Australia. To have allowed of such world-wide distribution the temperature of the seas must have been singularly uniform. But while not a few Silurian species were cosmopolitan, many others appear to have had a more restricted range. Thus it may be inferred that, however uniform the climatic conditions may have been, the uniformity nevertheless was only comparative, and that even in Silurian times the oceanic areas had their distinct life provinces. By systematic studies of the lithological characters and fossil content of similar and contrasted provinces it may be possible eventually to picture in some measure the geographical conditions which obtained in times as remote even as the Silurian period. See also the articles MURCHISON (SIR RODERICK) and GEOLOGY in this work.

Siluridæ, or CAT-FISHES, a large family of fresh-water fishes, included in the order Physostomi. The skin is naked, or equipped with some bony scutes, never with scales; the dorsal fin is short and is occasionally absent—when present it is inserted above or in front of the ventrals; there is generally an adipose fin; the maxilla is very small; the barbels are well developed. The family is represented in most parts of the world. In Europe, however, there is only one Siluroid, the Sheat-fish or Shadden (*Silurus glanis*), which occurs in some eastern and central regions—e.g. in the Danube and the Elbe. In size it sometimes approaches the sturgeon, and is a sluggish but very voracious animal, and has been the subject of many strange stories. In North America most of the common cat-fishes belong to the genus *Aminurus*; in tropical America the genus *Pimelodus* has many representatives (see CAT-FISH). In many species of

Arius—a marine genus—common in the East Indies and on both coasts of Central America, the males hatch the eggs in their mouths. Species of *Doias*,

Silurus glanis.

common in South America, are remarkable for their habit of travelling from one pond to another. In northern Africa the most remarkable Siluroid is the Electric Cat-fish, *Malapterurus electricus*.

Silver (sym. Ag; atomic weight, 107·88; atomic number, 47; specific gravity, 10·42 to 10·57), a precious metal of a peculiar and beautiful white colour, by which it can be distinguished from all other metals or alloys, except one or two rare metals, such as lithium and indium. Silver is harder than gold, but softer than copper. It takes a very high polish, and for this reason was sometimes used for making small mirrors by the ancient Romans. It ranks next to gold in malleability and ductility, the thinnest silver-leaf produced by hammering being only $\frac{1}{100000}$ of an inch thick; and a wire of the metal can be drawn so fine that a length of 130 yards weighs only one grain. Silver conducts heat and electricity better than any other metal, for which reason it is adopted as the standard represented by 100. The emissivity or capacity for radiating heat of burnished silver is less than that of any other substance, being one-fiftieth of that of lamp-black. Silver does not suffer even from long exposure to the atmosphere, except that it readily tarnishes when sulphuretted hydrogen or animal exhalations containing sulphur are present. Both nitric and sulphuric acid dissolve silver; and aqueous hydrochloric acid, as well as a solution of common salt, converts the surface of the metal into the chloride of silver. The metal is useful for laboratory utensils as it is not attacked, as are glass and platinum, by fused caustic alkali. Silver melts, in the absence of air, at 1760° F. (960° C.), and, when molten, has the remarkable property of absorbing oxygen. The so-called 'spitting' of silver is the almost explosive expulsion of oxygen which occurs when a mass of silver is quickly cooled from the liquid to the solid state. The metal volatilises at about 2000° C., the vapour being bright blue. When silver is deposited by a reducing agent upon a glass surface from ammoniacal solution it may be obtained as an excessively thin film, which again is blue to transmitted light.

Silver is rare among Neolithic relics, but it was known in Egypt at an early period. It was a great favourite among the nations of antiquity, ancient Greek and Roman statuettes, vases, coins, &c., of silver being among the treasures of the chief museums. Diodorus Siculus (1st century B.C.) records that silver was first found in Spain by shepherds who set fire to a Pyrenean forest and so melted silver from veins. The story may have a substratum of truth, and throws light upon a probable manner of discovery of other metals besides silver which are easily reduced from certain of their ores. In 1630 an Indian on the Cerro de Pasco, Peru, lit a camp fire on the mountain side and found next morning that he had melted silver from the rock below the ashes; he thus discovered a vein which later became famous for copper as well as silver.

Oxides of Silver.—There are two oxides; the better-known argentic oxide, Ag_2O , is made by adding pure potash or soda to a solution of silver nitrate. Argentic oxide when moistened absorbs carbonic acid from the air. It decomposes and loses its oxygen at 572°F . (300°C), and ignition takes place when it is rubbed in a mortar with sulphide of arsenic or of antimony and other easily oxidisable substances. The other oxide of silver is the *Peroxide*, Ag_2O_2 .

Sulphide of Silver, Ag_2S .—The strong affinity silver has for sulphur is seen from the readiness with which it blackens in an atmosphere containing sulphuretted hydrogen. A silver coin can be easily darkened by rubbing it with sulphur or by placing it in contact with vulcanised india-rubber, which contains sulphur. Sulphide of silver can be prepared by melting together silver clippings and sulphur in a covered crucible. It is also formed when sulphuretted hydrogen or a soluble alkaline sulphide is added to an aqueous solution of a salt of silver, the silver sulphide precipitating as a black powder. The tarnish on silver articles which from their nature cannot be easily rubbed with leather and rouge or brushed can be readily removed by an aqueous solution of cyanide of potassium; but as this salt is poisonous the article should be afterwards carefully washed. Silversmiths perfectly restore the original white colour to darkened silver objects by heating them in contact with carbonate of soda and nitre. Statuettes and other art objects in silver are frequently 'oxidised,' as it is called. This is really darkening their surface more or less by a film of sulphide produced by immersing them in a hot solution of sulphide of potassium. The prominent parts are then brightened by brushing or otherwise. The native compounds of silver and sulphur (ores) are noticed below.

Chloride of Silver, AgCl .—This salt is prepared by adding to an aqueous solution of the nitrate of silver either hydrochloric acid or chloride of sodium (common salt), when a thick, white, curdy precipitate of the chloride is thrown down. The precipitate requires to be washed and dried in the dark, and it is then an anhydrous white powder. When fused and allowed to cool it becomes waxy and hornlike, in which state it is translucent or even transparent in thin plates. In this massive condition it is still sometimes called by the old name of *horn silver* or *luna cornea*, whether native or artificially prepared. Chloride of silver is very insoluble in water, so that an extremely small proportion of silver may be detected in water by the formation of chloride. It dissolves in ammonia-water and cyanide of potassium or sodium. When a solution of chloride of silver in ammonia-water is boiled a fulminating compound is deposited; but this can be avoided by evaporating the solution at a gentle heat, by which treatment scales of the chloride separate. As commonly prepared, chloride of silver blackens by exposure to daylight. Native chloride of silver is an important ore of the metal, and is referred to below.

Cyanide of Silver, AgCN , is obtained by precipitation as a white powder when hydrocyanic acid or cyanide of potassium is added to an aqueous solution of nitrate of silver. It is insoluble in water, but aqueous solutions of ferrocyanide of potassium, hyposulphite of soda, and ammonia and some of its salts dissolve it. It forms double salts with various metallic cyanides, one of these, the *argentocyanide of potassium*, being of great service in Electro-metallurgy (q.v.). Mr A. Wright, surgeon, Birmingham, first applied this salt to electroplating, his invention having been bought and patented by the Messrs Elkington in 1840.

Nitrate of Silver, AgNO_3 , is the most important

salt of the metal. It crystallises in colourless tabular plates belonging to the prismatic system, has a specific gravity of 4.355, and fuses at a low temperature, forming after solidification the *lunar caustic* used as an escharotic by surgeons. If during fusion the temperature is allowed to rise above 383°F . (198°C .) the salt is decomposed. Nitrate of silver dissolves in rather less (783) than its own weight of water at 51.8°F . (11°C .), and is more soluble at higher temperatures. It is prepared by dissolving silver in moderately strong nitric acid with the aid of heat, and has a very bitter taste. Unless in contact with organic matter, nitrate of silver is not blackened or discoloured by the action of light. An ink for marking linen or cotton is prepared by dissolving 2 parts by weight of nitrate of silver and 1 part of gum-arabic in 7 parts of water, a little Indian ink being added. For the use of nitrate of silver in taking photographic pictures, see PHOTOGRAPHY. Black stains upon the hands or upon linen caused by nitrate of silver may be removed by a strong solution of iodide of potassium, or more efficiently by cyanide of potassium, which, however, is poisonous. When phosphorus is kept immersed in an aqueous solution of nitrate of silver the metal is reduced. This supplies a means of coating delicate objects with a film of silver. The article is dipped for a moment in bisulphide of carbon containing $\frac{1}{2}$ of its weight of phosphorus in solution. As the bisulphide evaporates, phosphorus is left in a state of fine division over the surface of the object, which is then dipped into an aqueous solution of nitrate of silver, from which silver is reduced by the phosphorus. Such objects as insects, feathers, and lace can be thus coated with silver, but adroitness is necessary, as finely-divided phosphorus takes fire spontaneously.

Sulphate of Silver, Ag_2SO_4 .—This salt is formed either by adding sulphate of soda to an aqueous solution of nitrate of silver, when it is thrown down as a precipitate, or by boiling granulated silver with sulphuric acid. The process for 'parting' an alloy of silver and gold by sulphuric acid is referred to below.

Silver can be removed from old plated articles by boiling them in a menstruum of 3 lb. of sulphuric acid, 1 lb. of water, and $\frac{1}{4}$ oz. of nitrate of potash. The silver in the solution is then precipitated as the chloride, and from this the metal is recovered.

ORES OF SILVER.—The greater part of the world's supply of silver is obtained as a by-product from *argentiferous galena* and *copper ore*. All galena contains silver, though in very variable proportion. When that proportion exceeds about 3 ounces per ton it is generally worth extracting. Commonly, the finer-grained varieties of galena are the more argentiferous. Silver and copper are frequently associated, and many important lodes have yielded silver in their oxidised 'gossans' (see ORE-DEPOSITS) and copper at greater depths. The deposits of Cerro de Pasco (Peru), Butte (Montana), and Ducktown (Tennessee) are instances in point.

Native Silver is not uncommon in the gossans of silver-bearing veins; it occurs as sheets, scales, laminae, and wires, and (rarely) in the crystalline form (cubical system). The Kongsberg mines, Norway (opened 1623), have long been famous for their native silver, which is sometimes found in masses of considerable size; the largest weighed 1537 lb. A piece of silver weighing 1842 lb. was extracted at the Smuggler mine, Aspen, Colorado, in 1894; while in 1860 a mass of 8 tons is said to have been mined at Hien de la Encina, Spain. Important finds of native silver have been made in the Cobalt region, Ontario; a vein 5 feet wide of nearly pure silver was exposed there at the Nipissing

mine in 1906, and later 3000 lb. of solid silver was taken out of the shallow workings. Native gold usually contains some silver, and when the proportion of the latter exceeds 20 per cent. the native alloy is called *electrum*. Some specimens of electrum from Transylvania contain as much as 38 per cent. silver. Native silver occurs with native copper in Michigan. A native silver amalgam containing 13½ per cent. mercury is worked near Coquimbo, Chile; it is called *arquerite*. Similar amalgams have been found at Almadén, Spain, Allemont, France, &c. Compounds of silver and tellurium, and of gold, silver, and tellurium, are of value in some districts.

Much silver is obtained in Mexico and Chile from *Argentite* or *silver glance* (Ag_2S). It occurs in the Comstock mine, Nevada, and sparingly in Europe and Cornwall. Crystallising in the cubic system, it contains 87 per cent. silver when pure. *Stephanite* or *brittle silver ore* ($5\text{Ag}_2\text{S} \cdot \text{Sb}_2\text{S}_3$) is a common associate of argentite and a valuable ore in Mexico and Peru; it crystallises in the rhombic system, and contains 71 per cent. of the metal. There are two *red silver ores*, i.e. *pyrrargyrite* ($3\text{Ag}_2\text{S} \cdot \text{Sb}_2\text{S}_3$), which is dark red, and *proustite* ($3\text{Ag}_2\text{S} \cdot \text{As}_2\text{S}_3$), which is light red in colour; they are frequently found together. *Polybasite* is an iron-black mineral containing silver, copper, antimony, and arsenic; while *freieslebenite* is steel-gray, and contains lead and antimony as well as silver; both are valuable when they occur in quantity. *Horn Silver* or *terargyrite* (AgCl) is an important ore in South America; it is also found at Comstock (Nevada), Broken Hill (New South Wales), in California, Harz Mountains, and (rarely) in Cornwall. It usually occurs as a massive, wax-like, non-crystalline form which cuts like wax. Other silver minerals are only occasionally of economic importance.

PRODUCTION AND VALUE OF SILVER.—Mexico has, since the beginning of the century, recovered its old-time predominance as the premier silver-producing country of the world. It is closely followed by the United States; then by Canada and Australia. The supremacy of the American continent in silver-production is noteworthy: in 1922, of the world's total output of 192 million ounces, America contributed over 165 million. According to official figures, Mexico has produced 6000 million pesos of silver since 1521; the equivalent currency value is about 600 million pounds sterling. The principal silver-mining districts in Mexico are in the states of Guanajuato, Zacatecas, San Luis Potosí, and Hidalgo. Silver-bearing lead and copper ore is widely distributed in the United States, Utah, Missouri, Idaho, Montana, Nevada, and Colorado being prominent in this connection. The Comstock lode, Nevada, is one of the richest and most remarkable in the world, and has yielded about 80 million pounds worth of precious metals, of which silver accounts for three-fifths. The mines are deep and very hot. In some places the men can only work in 15-minute spells in a blast of cold air with a spray of cold water. The principal silver district of Canada is the Cobalt region, Ontario, the output of which reached its zenith in 1911, with 31½ million ounces. The veins were discovered during the making of the Timiskaming and North Ontario railway; they are numerous, and though usually only a few inches wide, their walls are mineralised, and each therefore presents a considerable width of workable ground. The greater part of Cobalt's silver has been obtained at depths less than 300 feet. The silver yielded by Australia is a by-product of lead and copper mining. The Broken Hill lead-zinc mines, New South Wales, contribute fully 80 per cent. of that continent's silver, the remainder coming from Mount Lyell, Mount Morgan, and

numerous smaller lead mines. The Broken Hill mines support about 4500 men, and have produced 33 million tons of ore worth 112 million pounds, the silver output totalling 370 million ounces. Silver is a commodity whose price is particularly sensitive to the ebb and flow of world business conditions; and the great consuming centres of the Far East, where more than 700 million people use currency based almost entirely upon the metal, are the principal sources of demand. The price of bar silver is usually stated in pence per standard ounce, 925 fine. It varied but slightly from an average of 60d. during the period 1845 to 1874; then there was a decline due to increased production, the minimum price of 23·3d. having been reached in 1902. At the outbreak of the Great War the price was almost 26d. per ounce; the war period saw an increase up to the maximum of 85d., which occurred in February 1920; then a rapid fall ensued. The average price in 1922 was 34·4d. per ounce. The nominal or coinage value in Britain is 66d. per troy ounce.

METALLURGICAL PROCESSES.—The metallurgical processes in use for the extraction of the metal from its ores are very varied. The scarcity or abundance of fuel is an important question in determining what process can be most economically employed. The three important methods of separating silver from its ores are (1) by forming an amalgam of silver with mercury, from which the latter is afterwards separated by distillation; (2) by converting the silver in sulphuretted ore or regulus into a soluble salt, and from its solution precipitating the silver by metallic copper or iron; (3) by forming a rich alloy with lead, as through the smelting of silver ores with galena or other lead ore, from which the silver is afterwards separated by cupellation.

Amalgamation Processes.—The Mexican or Patio amalgamation process, invented by Bartholomé de Medina in 1557, has been practised with but little alteration down to the present time. Silver is one of the metals with which mercury unites at common temperatures, though the amalgamation proceeds more quickly as the temperature increases. The ore, first broken into small pieces by stamps or edgestone mills, is most frequently ground in Mexico in a circular trough (*aravastre*), in some cases 9 feet in diameter and 1 foot deep, with a flat bottom formed of hard stones. In the centre revolves a vertical shaft on which are fixed four arms, each dragging a heavy stone by which the ore is reduced with water to a fine mud.

In the Patio process, which is suitable for sulphuretted silver ores, the materials used besides the ground ore are *magistral* (sulphide of copper roasted, so as to produce as much sulphate as possible), common salt, and mercury. The ore, at first a fine mud, is partially dried and worked into flat circular heaps, which, though sometimes smaller, generally contain from thirty to sixty tons. Salt-earth is then added in such quantity as will yield chloride of sodium amounting to fully 6 per cent. of the ore, a limited quantity of water being used. After a mixture of this salt with the ore is made the heap is made circular and trodden by horses for two hours, the mixture being turned over by men in the middle of the operation. The next step is to add about 2 per cent. of *magistral*, which is spread over the ore and incorporated with it, also by the feet of horses. If the ore under treatment contains about 60 ounces of silver per ton, then mercury to the extent of 24 lb. per ton is spread over the heap in small globules by pressing it through linen bags. Only about two-thirds of this mercury is, however, added in the first instance, and the mass again trodden for two hours by horses. The ore in the heap, now called

a *torta*, is next turned over by men, and horses once more trot over it for a rather longer time. After this the mass is left to rest for a day, when horses again travel over it. The second portion of mercury is added. Further treading by horses and turning over by men follow at intervals of days, the completion of the amalgamation process taking about a fortnight in summer and considerably longer in winter. The dry amalgam produced by the above operations now receives an addition of mercury to render it liquid enough to admit of its being separated from the slime by washing.

For what is called the *Cazo* or *Caldron* process—i.e. the hot amalgamation method as practised to some extent in Mexico, but more generally in South America—the suitable ores are those containing native silver or those consisting of silver in union with chlorine, bromine, or iodine. It is unsuited for sulphuretted ores. After having been ground, dressed, and washed the ore is put into a cauldron with a thick copper bottom, along with water to form a thin mud. A fire is then lighted beneath it, and just before the liquid stuff begins to boil common salt to the amount of about one-sixth part of the weight of the ore is added, and enough mercury put in, but not all at once, to form a soft amalgam. The liquid is constantly stirred by revolving arms on an upright shaft with copper blocks attached to them. In about six hours the operation is completed, and the amalgam is then separated from impurities. Care is necessary in this process not to use excess of mercury, which should not be more than four times that of the silver by weight. A greater quantity produces adhesion of the silver amalgam to the copper, and sometimes a copper amalgam is formed if the blocks rotate too slowly.

The amalgam, after being subjected to filtration through canvas, is distilled in an iron bell-shaped vessel or cylindrical retort, by which the mercury is expelled as vapour and the fumes condensed in a trough containing water. The silver remains in the retort, and is afterwards cast into bars.

The *pan amalgamation process* was introduced soon after the silver ores of Nevada and adjoining states began to be worked. The pans are tubs 5 or 6 feet in diameter, and generally made of iron. Each has a vertical shaft passing up through the centre, upon which is fitted a revolving muller with iron shoes, which come almost close to dies fixed to the bottom, and between which the pulp passes. This shaft is kept in motion by spur gearing, and there is usually a double bottom to the pan for heating by steam. Fig. 1 shows a familiar type in section. These vessels are charged half-full of crushed ore and water, and they are designed with the intention of uniting as far as possible a grinding with a stirring surface. Common salt, sulphate of copper, and sometimes other chemicals are added to the charge. A pulp is produced just thick enough to allow the muller to rotate, and the temperature of the charge is raised by steam to from 160° to 200° F. The necessary quantity of mercury is added, and the pulp containing the amalgam is ready to be removed after the charge has been in the pan five hours. The amalgam is then cleaned and strained, and the mercury separated from the silver by distillation in a cast-iron retort.

Ziervogel's process is a wet process best adapted to the treatment of argentiferous copper mattes (mixed sulphides) obtained from the smelting of copper pyrites. The matte is ground and roasted to convert the iron sulphide into sulphate. On raising the temperature the latter is decomposed and copper sulphate formed. The mass is removed

from the furnace and finely ground. It is then charged into a reverberatory furnace where, by a careful regulation of temperature, copper sulphate is decomposed and silver sulphate produced; the latter is dissolved out by hot water in vats, and

Fig. 1.—Amalgamating Pan :

a, muller; b, shoes fixed to muller, c, dies fixed to bottom of pan; d, scraper; e, driving wheels; f, wings to prevent pulp rising too high; g, steam space.

the silver precipitated from the solution by means of metallic copper. The process is but little used to-day. Other once-famous wet processes, such as those of Augustin and Patera, have now been superseded by the cyanide process.

Cyanide Process.—The cyanide process of extracting silver from its ores, introduced near the close of the 19th century, is by far the most important wet process at the present time. The pioneer work was done at El Oro in 1895, where it was demonstrated that low-grade silver ores could be economically treated by cyaniding. The process is now in operation in all important silver-mining regions. The extraction of silver by weak solutions of potassium or sodium cyanide is the same in principle as that of gold (see GOLD, Vol. V. p. 288).

Smelting of Silver.—Combined lead and silver smelting, and the desilverisation of argentiferous lead, are described under LEAD. There are no silver ores properly so called produced in the United Kingdom, but foreign ores are smelted along with lead ores or rich lead slags.

Liquation Process.—Silver can be separated from argentiferous copper by this process, which consists in heating a fused mixture of the copper with a large excess of lead to a temperature above the melting-point of the latter, but below that of the copper. In this state of matters the lead liquates or sweats out of the mass, carrying with it the greater part of the silver which the copper contained. This silver can then be extracted from the lead by cupellation.

Cupellation.—This process consists in melting lead rich in silver on the hearth of a small furnace, and blowing air over its surface, the oxygen of which, under the influence of the heat, rapidly converts the lead into litharge or plumbic oxide. Fused litharge has the property of dissolving the oxides of some other metals, such as copper, zinc, tin, antimony, &c. Silver, however, is not oxidised by this treatment. The result of the operation is that the whole of the lead put in the furnace,

together with small quantities of other oxidisable metals (present as impurities), is removed as oxides, and the silver is left on the bed of the furnace. In the English cupellation-furnace the bed or hearth is movable, and is formed of an oval iron frame or test rammed full of powdered marl, cement, or bone-ash. The German cupellation-furnace (shown in fig. 2) is of larger capacity than

Fig. 2.—Silver Cupellation-furnace:

a, hearth of marl or clay; b, bricks; c, bed of slag; d, movable cover; e, e, tuyeres connected with bellows; f, fireplace; g, crane for lifting cover.

the English, and has a movable domed cover constructed of iron. The diameter of this furnace is about 10 feet, and the hearth is covered with marl. These furnaces differ only in details and in the way in which they are charged. In the United States what is termed a Steltz water-back cupel—a hollow casting through which water flows—is used in the first stage of cupellation.

There are three processes for separating silver from gold practised on a large scale. One of these is a very old method. It is called 'parting' by nitric acid. The alloy, which may consist of one part by weight of gold to two of silver or of one of the former to three of the latter, is melted and granulated—i.e. formed into small beads. It is then boiled (in platinum or earthenware vessels) with nitric acid, of 1.4 sp. gr. and an equal bulk of water, for several hours, till the silver is almost all converted into nitrate, the gold forming the residue after the dissolved silver is removed. To this solution of nitrate of silver common salt is added to precipitate the silver as chloride, from which the metal is reduced by the action of granulated zinc and weak sulphuric acid. The silver is then washed, pressed, dried, and melted, producing bars almost pure from the alloys generally treated.

Another method of 'parting' is by boiling the alloy in concentrated sulphuric acid. Auriferous silver, either granulated or in bars, is placed in cast-iron pots along with sulphuric acid, which is cautiously raised to the boiling-point. The silver, if it does not much exceed 200 lb. in weight, is dissolved in about eight hours, but sooner if granulated. The gold falls down as a sediment, and the sulphate of silver is drawn off by a platinum siphon or otherwise. The solution of sulphate of silver is then diluted with water, and the metal precipitated by scrap-iron. Impurities in the alloy sometimes render the sulphuric acid method of parting troublesome.

Separation of silver from argentiferous gold is now effected by chlorine, a method patented by F. B. Miller in 1867, and soon afterwards used at the Sydney mint and at other places. Gold, to the amount of 600 or 700 ounces, is melted in a clay crucible, and a little melted borax thrown in.

Chlorine gas is then admitted through a suitable pipe, the end of which almost reaches the bottom of the crucible, so that the gold is forced to bubble up through the molten gold. At first volatile chlorides of some of the baser metals, which may be present in very small quantity in the alloy, escape through holes in the cover of the crucible, but the chloride of silver does not. Chlorine is supplied till it is found that no more is absorbed, which shows that practically all the silver has been changed into chloride. When this is the case the crucible is allowed to cool sufficiently to allow the gold to solidify, and the red-hot liquid chloride of silver is then formed into slabs in moulds. This chloride generally contains 2 per cent. of gold, but it is eliminated by adding metallic silver, with which the gold forms an alloy. From the slabs of chloride of silver the metal is reduced by using them as one of the elements of an electrolytic cell.

Silver is largely used for coinage, plate, jewellery, and watch-cases, and for electroplating. Silver compounds are used in photography, in glass-staining, and in several chemical preparations, including marking-ink and hair-dyes. Like gold, silver is too soft to be used alone for vessels, jewellery, or coin, for which reason it is usually alloyed with copper. Further references to silver will be found in the articles on Alloy, Assay, Bimetallism, Chasing, Filigree, Embossing, Hall-marks, Mining, Mint, Mirror, Numismatics, Electro-metallurgy, Metalwork, Photography, and Repoussé.

Silver Fir. See FIR.

Silverfish, a name given to the Atherine (q.v.) to artificially bred Goldfish (q.v.), and to minute wingless insects, Lepisma, in the order Thysanura.

Silver Thaw, or GLAZED FROST (Fr. *verglas*), the icy face of things in general, including trees, produced sometimes at the beginning of a thaw, or when a fall of rain or a heavy mist occurs while the temperature at the earth's surface is below 32° F. and decidedly lower than the atmosphere a little higher up. A thin shell of ice is rapidly formed over everything subject to the conditions.

Silverton. See BROKEN HILL.

Silver-tree, a tree (*Leucadendron argentea*) of a South African proteaceous genus, has leaves covered with silky hairs which give it a silvery gray shimmer. They are sometimes used for painting on. Old trees are rarely fifty feet high: the usual height is about 20 feet. It is characteristic of the Cape Peninsula. It has been confused with the tropical *Terminalia sericea* (Combretaceæ), also silky-leaved.

Silverweed. See POTENTILLA.

Silvester. See SYLVESTER.

Silybum, or MILK-THISTLE. See THISTLE.

Simancas, a village of Spain, 7 miles SW. of Valladolid, where the national archives of Spain have been kept since the reign of Philip II. (1563). There are more than 30 million documents in all. Pop. 1000.

Simarubaceæ, a family of trees and shrubs, with alternate, generally compound leaves, without stipules; regular, generally hermaphrodite flowers. The species are not numerous; they are found in the tropical parts of Asia, Africa, and America. The whole family is characterised by

great bitterness, and several of the species are used as tonics in dysentery, &c. Quassia (q.v.), Bitterwood (q.v.), and Ailanto (q.v.) belong to it. Simauba is itself a genus with several species, all belonging to tropical America.

Simbirsk, renamed **ULIANOVSK**, a town of Russia, stands on the right bank of the Volga, 350 miles SE. of Nijni-Novgorod. It has two Greek cathedrals, a university (1919), a large trade in wheat, wool, fruits, and potash, and a famous annual fair. The town was rebuilt after destruction by fire in 1864. Kerensky's father was a schoolmaster here, and included among his pupils Lenin (Ulianov), who was born here in 1870. Pop. 68,000.

Simcoe, LAKE, in Ontario between Georgian Bay and Lake Ontario, 30 miles long and 18 broad.

Simeon. See **DURHAM** (**SIMEON OF**).

Simeon, CHARLES (1759-1836), evangelical preacher, born at Reading, was educated at Eton and King's College, Cambridge, was elected to his life-long fellowship at his college in January 1782, that same year took orders, and was appointed perpetual curate of Trinity Church, Cambridge, an office which he held till the close of his life. The impassioned evangelicalism of his preaching at first aroused a bitter and protracted opposition. But he made many converts and came to exercise an enormous influence all over England. He took a foremost part in founding the Church Missionary Society. His influence long survived his death by means of the society he established for purchasing advowsons. His *Horæ Homileticæ* (17 vols. 1819-28; new ed. 21 vols. 1832-33) contains as many as 2536 sermon outlines. See the *Memoirs* by the Rev. W. Carus (1857), *Recollections of Simeon's Conversation Parties* by Abner W. Brown (1862), and the *Study* by H. C. G. Moule (1892).

Simeon Stylites. See **STYLITES**.

Simferopol, renamed **AKMETCHET**, capital of Crimea, 50 miles by rail NE. of Sebastopol, has extensive gardens and vineyards. Pop. 70,000.

Simia, the Latin name for an ape or monkey, used by Linnæus in an almost equally wide sense. Technically, however, Simia is now reserved for the genus to which the Orang-utan (*S. satyrus*) belongs. Simiidae includes the Anthropoid Apes; Simiinae, the higher of the two sub-families of Simiidae, comprising the gorilla, chimpanzee, and orang.

Simile. See **METAPHOR**.

Simla, a British sanatorium, the headquarters of the British government in India during the hot months of summer, stands on the southern slopes of the Himalayas, in a beautiful situation, 170 miles N. of Delhi. Its first house was built in 1819, and it was first visited officially by the Indian government in 1827, having since 1864 been regularly made its headquarters every summer. There are here two viceregal residences (the newer one built in 1886), handsome government buildings (1884), a fine town-hall (1886), several European schools, and various public institutions.

Population 27,500 in winter, and about 45,000 in summer.—The *district* has an area of 100 sq. m. and a population of 45,000.—The name Simla Hill States is given to twenty-three Indian states, all

View of Central Simla.

small, in the neighbourhood of Simla. Their united area is 5489 sq. m., and their population is 306,718 (1921).

Simms, WILLIAM GILMORE (1806-70), American author, born at Charleston, South Carolina. His earliest volume, *Lyrical and other Poems*, was published in 1827. After *The Vision of Cortes* (1829), *The Tri-colour* (1830), and *Atalantis, a Story of the Sea* (1832), he poured out poems (perhaps the best *Southern Passages and Pictures*, 1839), novels (among them *The Yemassee*, *The Partisan*, and *Beauchampe*), histories, biographies, and magazine articles in rapid succession, almost till his death. His style is crude but vigorous, and his writings display strong imagination and many of the gifts of the born story-teller. There are *Lives by Cable* (1888) and *Trent* (1892).

Simmel, LAMBERT. See **HENRY VII**.

Simois. See **TROY**.

Simon, JULES, French statesman, economist, and author, was born at Lorient (Morbihan), 31st December 1814. He received the names of Jules François Simon Suisse, but on reaching manhood chose the designation of Jules Simon only. After a brilliant educational career, he succeeded Victor Cousin (whose ardent disciple he was) as lecturer on philosophy at the Sorbonne in 1839. He was returned to the Chamber of Deputies for the department of the Côtes-du-Nord in 1848, and took his seat with the Moderate Left. He refused the oath of allegiance to the empire, and by the year 1869 had become one of the most popular chiefs of the Republican party. He was minister of Public Instruction in the Government of National Defence; but in 1873 his measures dealing with secondary education were violently opposed by the clericals, and he resigned. He now became leader of the Republican Left. In 1874 he assumed the direction

of the *Siccle* newspaper; in 1875 he was elected a life-senator; and in 1876 he was appointed prime-minister, taking the portfolio of the Interior. President Macmahon and the Right, however, resented his liberal attitude towards the press, and he forthwith resigned. M. Simon pronounced the funeral oration on M. Thiers. He always showed himself a consistent advocate of Free Trade, and took a prominent part in the revision of the Constitution, but subsequently his Republicanism developed a more conservative character. In 1880 the French Academy elected him a member of the new Supreme Educational Council, and two years later he was elected permanent secretary of the Academy of Moral and Political Sciences. He died at Paris 8th June 1896. Besides editing Descartes, Bossuet, Malebranche, and Antoine Arnauld, and contributing to the *Revue des Deux Mondes* and other periodicals (his last work was *Indices et Portraits*, 1893), Simon was author of *Histoire de l'École d'Alexandrie* (1844-45); *La Liberté de Conscience* and *La Liberté* (1859); *La Religion Naturelle* (1856); *L'Ouvrière* (1861); *L'École* (1864); *Le Travail* (1866); *La Politique Radicale* (1868); *Souvenirs du 4 Septembre* (1874); *Le Gouvernement de M. Thiers* (1878); *Dieu, Patrie, Liberté* (1883); *Une Académie sous le Directoire* (1885); *Mémoires des Autres* (1889); some posthumous autobiographical works; and studies on Thiers, Guizot, Rémusat, Mignet, Michelet, Henri Martin, and others. See Life by Séché (1898).

SIMON, RICHARD, the father of biblical criticism, was born at Dieppe, May 13, 1638. He entered the Congregation of the Oratory in 1659, but soon after withdrew, to return in the later part of 1662. He was sent first to lecture on philosophy in the college of Juilly, but was afterwards appointed to catalogue the oriental MSS. in the library of the Order at Paris. His criticisms upon Arnauld's *Defence of the Perpetuity of the Faith in the Blessed Eucharist* caused great displeasure among the Port-Royalists, and his imprudent meddling with another controversy brought upon his head the wrath of the Benedictines. The scandal occasioned by the appearance of his *Histoire Critique du Vieux Testament* (1678) led to his again withdrawing from the Oratory and retiring to Belleville as *curé*. In 1682 he resigned his parish, and lived in literary retirement at Dieppe, Paris, and again at Dieppe, where he died April 11, 1712. Few writers of his age played so prominent a part in the world of letters, and especially in its polemics. There is hardly a critical or theological scholar among his contemporaries with whom he did not break a lance—Weil, Spanheim, Le Clerc, Isaac Voss, Du Pin, Jurieu, and Jurieu's great antagonist, Bossuet. His *Histoire Critique* (suppressed through Bossuet's influence, and only printed entire at Rotterdam in 1685) anticipates the most important conclusions of all the later rationalistic scholars of Germany, and also their method of investigation, and, indeed, is the first work which treated the Bible from the point of view of a literary product. For example, he disproves the Mosaic authorship of the Pentateuch, assigning its composition to the scribes of the time of Ezra. Other writings of Simon's are *Histoire Critique du Texte du Nouveau Testament* (Rotterdam, 1689); and *L'Histoire Critique des Principaux Commentateurs du Nouveau Testament* (Rotterdam, 1693), in which he assails the theology of the Fathers, and particularly that of Augustine, as a departure from the simple and less rigid doctrines of the primitive church. Among the Fathers his most esteemed authority was Chrysostom. Bossuet replied to this last work by his *Defense de la Tradition et des Saints Pères*. Simon frequently published under assumed names

—as his *Dissertation Critique* on Dupin's *Library of Ecclesiastical Writers*, under the name of Jean Renclin; a work, *Histoire Critique de la Créance et des Coutumes des Nations du Levant*, under the anagram of Monis; and a *Histoire de l'Origine et du Progrès des Revenus Ecclésiastiques*, under the name of Jerome Acosta.

See the Life by K. H. Graf in *Strassburger theol. Beitrage* (1847); A. Bernus, *Richard Simon et son Histoire Crit. du V. T.* (Laus, 1869), and the same scholar's *Notice Bibliographique* (Basel, 1882).

Simonides, a celebrated Greek lyric poet, was born at Iulis, in the island of Ceos, in the year 556 B.C. He repaired to Athens on the invitation of Hipparchus, and after his death took up his residence in Thessaly, under the patronage of the Aleuadæ and Scopadæ, who appear to have treated him in a very niggardly fashion. Shortly before the invasion of Greece by the Persians he returned to Athens, and devoted his poetic powers to celebrating the heroes and the battles of that momentous struggle in elegies, epigrams, and dirges. He carried off the prize, even from Æschylus, for the elegy on the heroes that fell at Marathon. He won as many as fifty-six times in these poetical contests. He spent his last ten years at the court of Hiero of Syracuse, where he died in 468. Simonides appears to have scandalised his contemporaries by writing for hire; and his great rival Pindar accuses him, apparently not without good reason, of excessive avarice. He brought to perfection the elegy and epigram, and excelled in the dithyramb and triumphal ode; he seems also to have invented the art of artificial memory. The characteristics of his poetry are sweetness (whence his surname of *Melicertes*), polish combined with simplicity, genuine pathos, and power of expression, although in originality he is much inferior to his contemporary Pindar.—Simonides of Ceos must be carefully distinguished from the iambic poet SIMONIDES of Amorgos, who flourished about 660 B.C.

Simonides, CONSTANTINE (1820-67), a Greek of great erudition, who used his marvellous skill in caligraphy partly in forging classical and early Christian manuscripts (though there is no reason to doubt the genuineness of some of his finds). He claimed to possess the History of Egypt of Uranus; to have deciphered some fragments of the New Testament dating from the 1st century, from the Mayer papyri now in Liverpool; and to have written, when at Mount Athos in 1840, the Codex (q.v.) Sinaiticus discovered there by Tischendorf (q.v.) in 1844 and 1859. See Farrer, *Literary Forgeries* (1907).

Simon Magus ('Simon the Magician'), the wicked sorcerer who thought that the gift of God might be purchased with money, and for this was excommunicated by Peter. The word *Simony* (q.v.) is derived from his name. When first introduced in Acts, viii. 9-24, Simon, apparently about 37 A.D., had already for a long time been a commanding personality in 'the city' of Samaria through his sorceries. Giving himself out to be 'some great one,' he had induced the people 'from the least to the greatest' to call him 'that power of God which is called Great.' Simon and the Samaritans had believed and were baptised under the ministry of Philip the Evangelist; and when the apostles Peter and John conferred on Philip's converts the gift of the Holy Ghost (including apparently the gift of tongues) Simon, hoping for new magical powers, went to the apostles and offered money that he might be enabled to confer the same gift. Peter's reply is known; Simon, rebuked, was submissive, and here the narrative of the Acts (written probably before the end of the 1st century) leaves him. But his penitence was

only temporary. Justin Martyr says Simon afterwards went to Rome in the reign of Claudius as a wonder-worker and was reckoned a god, having a statue erected to him by the senate and people with the inscription 'To Simon the Holy God.' Justin, himself a Samaritan, adds that 'almost all the Samaritans' and 'a few even of other nations' worshipped Simon as the 'First God,' and a woman Helena, who went about with him and had formerly been a harlot, they adored as his 'First Idea.' Irenæus follows Justin in the main, and adds that Simon professed to have appeared among the Jews as the Son, in Samaria as the Father, and to other nations as the Holy Spirit. From Simon, according to Irenæus, 'all sorts of heresies' derived their origin, including a particular Gnostic system. His followers worshipped images of Simon and Helena as Zeus and Athene. Hippolytus, who quotes much from Simon's work *The Great Announcement*, says that Simon encountered Peter at Rome, that he ordered his followers to bury him, promising to rise the third day, but that he never rose. Origen questions whether in his time there were more than thirty Simonians in the whole world. In the pseudo-Clementine *Homilies* and *Recognitions* (in their present form not older than the 3rd century) Simon comes into frequent conflict with Peter at Caesarea, Antioch, and elsewhere.

Baur in 1831 was the first to observe the indisputable fact that in some portions of these books it is the apostle Paul who is caricatured under the guise of Simon—portions he believed to come from 1st-century Ebionite sources. Others of the Tübingen school went further and traced the whole story of Simon to the antipathy of the Jewish Christians against the apostle Paul, whom they regarded as a pretender (the false as opposed to the true Simon), a 'Samaritan,' a libertine, and a bewitcher of men. Now, however, it is generally agreed that some facts regarding Simon must be accepted as historical, and that likely enough a pseudo-Messiah named Simon appeared in Samaria in the fourth decade of the 1st century. Perhaps Klostermann and Wendt are right in holding that the 'power of God which is called Great' (Gr. *Megalē*) ought to be interpreted according to the Samaritan word *Megala* ('Revealer'). Simon's 'revelation' or new religion had apparently for its main articles a doctrine of the essential oneness of many widely different cults—hence the attempted fusion of Baal, Zeus, the Father, the Son, the Holy Spirit—and a 'syncretistic-gnostic' conception of the world and its creation, together with ethical Antinomianism.

But it is obvious that the story of Simon has received accretions from a variety of extraneous sources. Thus, Justin was wrong about Simon's statue at Rome, the inscription he quotes being almost certainly identical with a dedication (still extant) by a private individual to Semō Sancus, a Sabine deity. The statement of Irenæus that Simon and Helena (called in the Clementines *Selēnē*, 'the moon') were worshipped under the images of Zeus and Athene may rest on a misapprehension of the Syrian Baal and Astarte worship, or on a misunderstanding of the Semitic word *Shem* or *Sem* ('name'). Further, no one now believes that *The Great Announcement* cited by Hippolytus as Simon's dates from so early a period. Opponents have mixed him up with other sorcerers of Cyprus, Caesarea, and Rome; and his disciples, anxious to combine as many elements as possible in their new world-religion, added to the confusion by their readiness to identify their master with the most incongruous personalities. Simon is a true magician in this at least, that he still eludes our grasp. The legend of Simon and Helena continued to be read in the middle ages; and several traits of Simon may be recognised in 'Doctor Faustus.'

See Baur's *Paul*, and his *History of the Church in the First Three Centuries* (both translated), and earlier works there cited; Hilgenfeld's *Clem. Recognitions u. Homilien* (1848); Zeller's *Apostelgeschichten* (1854); Lipsius in Schenkel's *Bibel-Lexikon* (1875) and his *Apokr. Apostelgeschichten* (1877); Harnack's *Gnosticismus* (1878), and his *Dogmengeschichte* (1886); F. Legge, *Forerunners and Rivals of Christianity*, vol. 1. chap. vi. (1916).

Simonoseki. See SHIMONOSEKI.

Simonstown, on False Bay, 20 miles S. of Cape Town, is the naval headquarters of South Africa; pop. 5400

Simony (derived from Simon Magus), in English law, means, according to Blackstone, the offence of obtaining orders or a license to preach by money or corrupt practice. But the term is now commonly used to denote the offence of presenting or procuring presentation to a benefice for money. In the canon law this was considered a heinous crime and a kind of heresy. As the canonical punishment, however, was not deemed sufficient, a statute was passed in the time of Elizabeth defining its punishment. A simoniacal presentation was declared to be utterly void, and the person giving or taking the gift or reward forfeited double the value of one year's profit; and the person accepting the benefice was disabled from ever holding the same benefice. Presentation bonds, however, taken by a patron from a presentee to resign the benefice at a future period in favour of some one to be named by the patron, are not illegal, provided the nominee is either by blood or marriage an uncle, son, grandson, brother, nephew, or grandnephew of the patron, and provided the bond is registered for public inspection in the diocese. The result of the statutes is that it is not simony for a layman or spiritual person, not purchasing for himself, to purchase, while the charge is filled, either an advowson or next presentation, however immediate may be the prospect of a vacancy, unless that vacancy is to be occasioned by some agreement or arrangement between the parties. Nor is it simony for a spiritual person to purchase for himself an advowson, although under similar circumstances. It is, however, simony for any person to purchase the next presentation while the church is vacant; and it is simony for a spiritual person to purchase for himself the next presentation, although the charge be occupied. Under powers conferred on them by an act of 1919, the National Assembly of the Church of England have passed a measure which will gradually remove the possibility of simony. The right of patronage to a benefice will be incapable of sale after two vacancies (subsequent to 14th July 1924) have occurred. The restriction does not apply to sales of land to which advowsons are appendant, which are included in the sale. See ADVOWSON, and Cripps's *Laws of the Church and Clergy*.

Simoom, or SIMOON (Arab. *samm* or *samūn*; from *samm*, 'poisoning'), is a hot, suffocating wind common in the deserts of Africa and Arabia, as well as in Sind and Beluchistan. It is essentially of the same nature as a cyclone: there is a central tract of calm surrounded by violent eddies of intensely heated air, and the entire system keeps moving slowly forward, generally from south to north or from east to west. Its presence is heralded by whirling currents of air, and indicated by the purple colour of the atmosphere. It often carries with it huge rotating columns of sand, or stifling gusts and showers of fine sand. It is highly deleterious to men and animals, causing the sensation of suffocation, together with great pain in the limbs. Spring and summer are the usual times of its occurrence; but it seldom lasts

many minutes, not more than twenty at the outside. See DESERT, STORMS.

Simplicissimus. See GRIMMELSHAUSEN.

Simplon (Ital. *Sempione*), a mountain-pass (6594 feet high) of Switzerland. The Simplon Road, leading over a shoulder of the mountain from Brieg in Valais to Domo d'Ossola (41 miles) in Piedmont, was commenced in 1800 by Napoleon, and completed in 1807 at a cost of £720,000. It is carried across more than six hundred bridges, over numerous galleries cut out of the natural rock or built of solid masonry, and through great tunnels. Close to the highest point is the New Hospice (opened in 1825), one of the twenty edifices on this route for the shelter of travellers. After much preliminary negotiation, the convention between Italy and Switzerland for the construction of a railway tunnel through the Simplon was finally approved at Rome and Bern in December 1896. There are two parallel tunnels, 21,576 yards long, about 60 feet apart, with connections every 670 feet, at a height above the sea of 2312 feet. The Swiss terminus is at Brieg, the Italian at Iselle. Operations were commenced in 1898; early in 1905 the two borings met; the tunnel was opened to traffic in May 1906.

Simpson, SIR JAMES YOUNG, physician, was born at Bathgate, Linlithgowshire, 7th June 1811, a baker's son, the youngest of a family of eight. He early showed a peculiar talent for medical observation and research; and in the prosecution of his professional studies at the university of Edinburgh, which he entered at the age of fourteen, he so attracted the notice of his teachers as to inspire all of them with an active interest in his future career. He took his M.D. in 1832, his thesis on *Death from Inflammation* winning the highest admiration; and in 1835 was elected president of the Royal Medical Society. Professor Thomson chose him as his assistant (1837-38), and employed him in the preparation of his course of lectures on General Pathology. During the illness of the professor he supplied his place in the lecture-room with unusual skill and address. He now began professional practice on his own account, and in 1840 succeeded Professor Hamilton in the chair of Midwifery. This position he held with yearly enhanced distinction, and by the rigidly scientific, while popularly attractive, character of his prelections contributed greatly to the renown of the Edinburgh school, both at home and abroad. He was indefatigable, amid the distracting cares of an extensive practice, in promoting the scientific perfection of his art; and his *Obstetric Memoirs* (2 vols. 1856), edited by Drs Priestley and Storrer, contains the fruits of much patient and ingenious research. Sulphuric ether had been employed in America by Morton to produce Anæsthesia (q.v.) during the extraction of teeth; but to Simpson belongs the credit of first, in March 1847, at the suggestion of a chemist, David Wardie, introducing chloroform as an anæsthetic to the medical world. In 1859 he recommended the stopping of hæmorrhage by Acupressure (q.v.). In his own peculiar field of obstetrics his improvements on the old methods of practice were numerous and valuable; his antiquarian researches are embodied in his posthumous *Archæological Essays* (1872). He was created a baronet in 1866, and died 6th May 1870. A bronze statue was erected in Edinburgh in 1877.

Besides the *Obstetric Memoirs* already mentioned, his medical and archæological works include a volume on *Acupressure* (1864), one on *Homeopathy*, *Selected Obstetrical Works*, *Anæsthesia*, *Clinical Lectures on the Diseases of Women*, and many papers and notices read

before the Royal and Antiquarian Societies of Edinburgh. See the *Memoir* by Duns (1873), and works by his daughter (1897) and Laing Gordon (1897).

Simpson, THOMAS, one of the most eminent of the numerous non-academic mathematicians of England, was born on the 20th August 1710, at Market Bosworth in Leicestershire. His father was a stuff-weaver, and, intending his son to follow the same occupation, gave him little or no education. The son, however, had a taste for study, and embraced every opportunity for gratifying it. In consequence he quarrelled with his father and went to Nuneaton. There he worked at his trade, and eked out his earnings by teaching an evening school and by casting nativities. The last occupation threatening to get him into difficulties, he removed to Derby, where he remained from 1733 to 1735 or 1736. Thence he went to London, and began teaching mathematics. In 1743 he was appointed professor of Mathematics in the Royal Academy at Woolwich, and in 1745 was admitted a Fellow of the Royal Society. He was the author of numerous treatises on algebra, trigonometry, &c. He died on the 14th May 1761. A biographical notice by Dr Charles Hutton, giving some curious details of Simpson's life, is prefixed to Davis's edition (1805) of the *Doctrine and Application of Fluxions*.

Simrock, KARL JOSEPH, a German poet and scholar, whose name is indissolubly associated with the revival of interest in old German literature, was born at Bonn, 28th August 1802, and studied at the university of his native city and at Berlin. His first work was a translation into modern German of the *Nibelungenlied* (1827). Compelled on account of a revolutionary poem to leave the Prussian state service, he devoted himself entirely to literature, especially old Germanic literature, and modernised in excellent style the poems of Walter von der Vogelweide (1833), Wolfram von Eschenbach's *Parzival* (1842), *Reineke Fuchs* (1845), *Die Edda* (1851), Gottfried von Strassburg's *Tristan und Isolde* (1855), the *Heliand* (1856), *Beowulf* (1859), *Der Wartburgkrieg* (1858), Brant's *Narrenschiff* (1872), &c. He also translated Shakespeare's poems and some of his plays, and published *Quellen des Shakespeare in Novellen, Märchen, und Sagen* (3 vols. 1831), in conjunction with Echtermeyer and Henschel; *Novellenschatz der Italiener* (1832); *Rheinsagen aus dem Munde des Volkes und Deutscher Dichter* (1836); a collection of German *Volksbrüder* (13 vols. 1844-67); *Das Heldenbuch* (6 vols. 1843-49); his own *Gedichte* (1844); and a considerable number of handbooks. In 1850 he was appointed professor of Old German Language and Literature at Bonn, a post which he held till his death, on 18th July 1876. See a monograph on him by Hocker (Leip. 1877).

Sims, GEORGE ROBERT (1847-1922), born in London, joined the staff of *Fun* in 1874, in 1877 began his 'Dagonet' contributions to the *Referee*, and also contributed series of papers to the *Weekly Dispatch*. He was a prolific writer on a variety of subjects. Among his plays are *Two Little Vagabonds*, *The Lights o' London*, *Harbour Lights*. His novels include *Rogues and Vagabonds*, *Memoirs of Mary Jane*, *Mary Jane Married*, *Memoirs of a Landlady*, *The Ten Commandments*, &c. In 1917 he published a volume of reminiscences.

Simson, ROBERT (1687-1768), was born in Ayrshire, was educated at the university of Glasgow, where in 1711 he was appointed professor of Mathematics, a chair which he occupied for half a century. One of the first subjects to which he turned his attention was the restoration of Euclid's lost treatise on *Porisms*. It is Simson's greatest achievement that he elucidated the nature of the

ancient porisms, though his restoration of them is not complete, but his treatise on the subject did not appear till after his death. His *Sectiones Conicæ*, in five books, was published in 1735; the first three books were afterwards translated into English, and were repeatedly printed. His restoration of Apollonius' *Planæ Locæ* had been finished about 1738, but was not published till 1749. The work by which he is best known is his *Elements of Euclid*, which appeared in Latin and in English in 1756. It contained the first six books, the eleventh and twelfth, and was the basis of nearly all the editions published for more than 100 years afterwards. In 1761 he resigned his professorship, and his only publication after his retirement was a second edition of the *Elements* (1762), to which he annexed the book of *Data*. In 1776 a large volume, *Roberti Simson Opera quedam reliqua*, was printed at the expense of Earl Stanhope, one of Simson's intimate friends, and liberally distributed. It contains a restoration of Apollonius' two books *De Sectione Determinata*, with the addition of other two *De Porismatibus*, and two tracts on logarithms and the limits of quantities and ratios. See Memoir by Trail (1812).

Sin is not simply moral evil as recognised by the awakened human conscience, but guilt before God or the gods. Some doctrine of sin, and of the mode of averting the anger of the deity, of reconciling him, and of escaping from the guilt, is accordingly part of most religions, ancient and modern. Zoroastrianism is a conflict of sin and holiness. The central doctrine of Buddhism turns on the demerit of human actions and human life, which must be purged by transmigration. But in no sacred books is the sense of sin so keen and developed as in the Bible—in the writings of the prophets of the God of holiness, in the psalms, in the gospels, and in Paul's epistles. From Paul's various utterances on the great subject of sin the Christian doctrine professes to be but a development.

Throughout the Scriptures sin appears as that element in man which puts him at enmity with God, and for his salvation from its guilt and power required the work of a Redeemer (see CHRISTIANITY). Sin is not defined in Scripture, and it was not till the controversies between Pelagius and Augustine, at the end of the 4th century, that the doctrine received full development. The early Greek fathers regarded sin as opposition to the will of God, and as such involving death as its just penalty. But they did not affirm that the guilt of Adam's sin or the corruption of his nature descended to all mankind. Tertullian, in virtue of his doctrine of Traducianism, was bound to hold that sinfulness had been propagated from Adam to his descendants. But it was reserved for Augustine to maintain, against Pelagius, that Adam's sin completely corrupted his whole nature; that the corruption of his guilt and its penalty death pass to all his children; that man is born not merely corrupt, but in a state of sin, guilt, and liability to punishment; in virtue of Adam's *peccatum originale*, the offspring of Adam is a *massa perditionis*, incapable of knowing, or loving, or serving God, and naturally disposed, without grace, to pursue evil only, the will being enslaved to evil. Pelagius (q.v.) maintained contrary doctrines, and semi-pelagianism insists that in spite of the weakening of his powers through hereditary sinfulness man is yet not wholly inclined to evil. The Greek Church continued to deny hereditary guilt, and to affirm man's will as free as Adam's before the fall. Duns Scotus and his followers admitted that man had lost by Adam's fall *justitia originalis*, but laid stress on the freedom of the will. Thomas Aquinas taught that hereditary sin is truly sin,

and the unbaptised infant is damned. At the Reformation both Luther and Calvin asserted what they regarded as Augustinian and Pauline views. Zwingli looked on hereditary sin as an inherited evil or disease: Arminians and Socinians practically denied hereditary sin altogether. The problems connected with sin are closely akin to those connected with the origin of evil and the freedom of the will. The liberal philosophy of the 19th century together with the advances made in biological, psychological, and other sciences profoundly affected the traditional point of view. Kant had found the origin of sin in the human will. The Hegelians taught that sin was a necessary condition of the development of mankind; and Schleiermacher that the sinful state of man was a disturbance of his nature, not a necessary condition of it. Another school, with its chief representatives in O. Pfleiderer, Dr F. R. Tennant, and Mr S. A. McDowall, has been mainly influenced by the doctrine of evolution. Sin does not begin with a fall from a sinless estate but grows gradually as the race develops. In the evolution of the great 'world plan,' sins are really anachronisms; they are habits surviving from a previous stage of man's development, habits which have come to be regarded as inconsistent with progress.

The doctrine of the Thirty-nine Articles (Art. ix.) is as follows: 'Original sin standeth not in the following of Adam (as the Pelagians do vainly talk); but it is the fault and corruption of the nature of every man, that naturally is engendered of the offspring of Adam, whereby man is very far gone from original righteousness, and is of his own nature inclined to evil, so that the flesh lusteth always contrary to the spirit; and therefore in every person born into the world it deserveth God's wrath and damnation. The Westminster Confession teaches (chap. vi.): 'By this sin' (i.e. the eating of the forbidden fruit) 'they' (i.e. our first parents) 'fell from their original righteousness and communion with God, and so became dead in sin, and wholly defiled in all the faculties and parts of soul and body. They being the root of all mankind, the guilt of this sin was imputed, and the same death in sin and corrupted nature conveyed to all their posterity, descending from them by ordinary generation. From this original corruption, whereby we are utterly indisposed, disabled, and made opposite to all good, and wholly inclined to all evil, do proceed all actual transgressions.' Modern psychology, with its analysis of the conscious and subconscious, takes original sin to mean the tendency in man to give way to his lower instincts, instead of sublimating these to a higher end. It is not actual sin but rather the universal disposition thereto.

Sins have been divided into categories, as sins of omission and of commission, deliberate voluntary sins and involuntary sins, sins of infirmity, &c. The 'sin unto death' (1 John, v. 17), generally identified with the unforgivable 'blasphemy against the Holy Spirit' (Matt. xii. 31), or 'sin against the Holy Ghost,' is understood not to mean profane speaking against the person of the Holy Spirit, or resisting his operations, but a state of obstinate, malignant deadness of heart, and unrepentant and unhesitating hatred to all good. The distinction accepted by Catholic theology between mortal and venial sins is explained at CONFESSION.

Sinai is the name given to the triangular peninsula, now belonging to Egypt, which lies between the Gulf of Suez in the south-west and the Gulf of Akaba in the south-east. Towards the north it is separated from the Mediterranean by a broad belt of drifting sand over which runs the ancient desert road, and now the railway, between Egypt and Palestine. South of this the land gradually rises towards the centre of the peninsula, when, after attaining a height of some 4000 feet, the limestone and sandstone rocks abruptly break off in a series of precipitous cliffs. This almost waterless region is known as Badiet Tih, 'the plain of the wandering.' The road from Gaza crosses that from Suez to Akaba at the important central watering-place of el Nakhl, and then descends by precipitous passes to the foot of the great escarpment. Here a broad stretch of sand and gravel cuts across the peninsula from east to west, and divides the 'plain of the wandering' from the triangle of mountains to the south. This mountain region is in its turn divided into two by the well-watered Wady Feiran. The northern part consists of shelving masses of red sandstone of moderate height, deeply cut into wild and precipitous gorges, in the midst of which lie the ancient Egyptian turquoise and copper mines and the ruined sanctuary of Serabit el Khadem. South of the Wady Feiran rise the great granite peaks which have always been associated with the 'Giving of the Law.' The most northerly peak, Jebel Serbal (6734 feet), has from its majestic appearance been suggested as the site; but Jebel Mûsa (7359 feet), some twenty miles south-east, has the support of tradition. At its foot lies the famous fortress-convent of St Catherine. The adjoining peak, Jebel Katrin (8527 feet), is, according to mediæval tradition, the place of burial of St Catherine. An adjoining peak, Ras Safsaf (6540 feet), has also by some been claimed as the true Mount Sinai. There are also other lofty peaks to the east, such as Jebel Umm Shomer (8449 feet) and Jebel Umm Iswed (8236 feet).

The whole of this mountainous district is desolate and denuded of the trees and shrubs which once flourished in favourable spots. Though apparently waterless, at times there are rain-storms severe enough to produce raging torrents—dangerous to man and beast—in some of the wady beds, and water may usually be obtained in such spots at all seasons by sinking wells in the dry bottoms. A few thousand wandering Bedawin range through the peninsula and find pasturage for their scanty flocks in the loftier valleys.

The history of Sinai has now been traced back to the earliest historic times. There is evidence that the Egyptians worked the turquoise mines in pre-dynastic times, but the tablet of King Semerkhet (Ist dynasty), engraved on rock 394 feet above the bottom of the valley in Wady Maghara, and similar tablets of kings of the IIIrd, IVth, and VIth dynasties found in the region of the mines, but now removed to Cairo for safety, prove how intimate was the connection of this region with ancient Egypt. This is further shown by the excavation of Serabit el Khadem, a sanctuary of the moon god which flourished during the XIIth dynasty and was added to in the XVIIIth and XIXth dynasties.

Some writers are inclined to associate this remarkable sanctuary with the Hebrew law-giving, but

all the older authorities support the traditional view that the scene must be set at one of the granite peaks farther south—at Jebel Mûsa or Jebel Safsaf.

Belonging to an age many centuries later, there are many Nabatæan (q.v.) inscriptions on the rocks of Sinai.

During the 4th and 5th centuries A.D. many hermits settled in the peninsula, and from the reign of the emperor Justinian (527–563) we read of a fortified hermit-settlement known as 'The Bush.' In the middle ages this convent came to be known as that of St Catherine, and in the 14th century there were actually at one time 280 monks in residence, besides a great many moslem Arabs who were daily fed at their table. Despite many vicissitudes the convent survives—with 20 or 30 monks—to the present day, and its library is world-famous for the valuable manuscripts which have been found there, such as the great Codex Sinaiticus and the Syriac Codex of the Gospels.

During the Great War the peninsula of Sinai was in the hands of the Turks, who made el Nakhl a military centre, and managed to penetrate through the peninsula as far as the Suez Canal before they were finally driven northwards by the British advance in 1916.

See Hull, *Mount Seir, Sinai, and West Palestine* (Lond. 1885); Palmer, *Desert of the Exodus* (Camb. 1871); Stanley, *Sinai and Palestine* (1856); *Ordnance Survey of the Peninsula of Sinai* (3 vols., Southampton, 1869); Euting, *Sinaitische Inschriften* (1892); Petrie, *Researches in Sinai* (London, 1906); Weill, *La Presqu'île de Sinai* (1908); Eckenstein, *A History of Sinai* (S.P.C.K., London, 1921); Dobson, *Mount Sinai, a Modern Pilgrimage* (London, 1925).

Sinaloa, one of the Pacific States of Mexico with an area of 27,557 sq. m. and a pop. of 341,000. Cereal-growing, stock-raising and silver-mining are carried on. The capital is Culiacán (q.v.), 100 miles north-west of which is the small town of Sinaloa, with a pop. of 3000.

Sinapis. See MUSTARD.

Sinclair, MAY, novelist, born at Rock Ferry in Cheshire, and educated at Cheltenham, published her first short story in 1895. Her best known novels, *The Divine Fire* (1904), *The Creators* (1910), *The Three Sisters* (1914), *Mary Olivier* (1919), *The Dark Night* (1924), are characterised by great power, vitality, and sympathy, and are written from a full experience of life that always keeps in touch with contemporary ideas. Her work has had a great vogue in the United States. In *The New Idealism* (1922) she appeared among the philosophers.

Sinclair, UPTON, American writer, was born at Baltimore in 1878. His sensational novel *The Jungle* (1906), in which he exposed the conditions in the meat-packing industry in Chicago, led to reforms. Other works include *The Money Changers* (1908), *Plays of Protest* (1912), *Sylvia* (1913), *The Brass Check* (1920), and *Singing Jail-birds* (1924), and are largely coloured by Socialist propaganda.

Sind, or SINDH (also spelt *Sinde* and *Scinde*), in the north-west of British India, belongs to the presidency of Bombay, and is bounded on the N. by Beluchistan and the Punjab, E. by Rajputana, W. by Beluchistan, and S. by the Indian Ocean and the Runn of Cutch. It contains an area of 46,500 sq. m., with a pop. (1921) of 3,279,377. The seacoast (150 miles) is very low and flat, with the exception of the small portion beyond Karachi (Kurrachee), and is studded with low mud-banks formed by the Indus or with sand-hills, the accumulated drift from the beach. The province is traversed from north to south by the Indus (whence the name; see INDIA, Vol.

VI. p. 97), and includes the whole of its delta. Along each bank of the river is an alluvial tract of great fertility, from 2 to 12 miles wide, and mostly irrigated by artificial canals and water-courses, which, overflowing during the inundations, cover the soil with a silt so rich as to yield two, and sometimes three, crops in a year. The soil, nevertheless, contains in the north so much saltpetre, and in the south so much salt, that after the year's crops have been obtained these substances are extracted for home consumption and export. Between the Indus and its most easterly branch, the Nara, is an alluvial 'doab,' which, from want of irrigation, has become almost a desert. East of this is the Thur, a desert of shifting sand. West of the Indus the country is occupied by the desert of Shikarpur on the north, a desert not of sand, but of alluvial clay, the same as that of the delta, which only requires irrigation to render it fertile; and in the south it is traversed by the Hala Mountains. The climate is remarkably sultry and dry, the province being beyond the action of the south-west monsoon; during the long summer the thermometer averages 95° F., and ranges up to 120°; in winter it falls below freezing-point and rises to 80°. There are generally two harvests per annum; the first, or *rabi* ('spring') harvest, consists of wheat, barley, indigo, oil-seeds, gram, hemp, and tobacco; the second, or *kharif* ('autumn') harvest, of rice, millet, oil-seeds, pulses, and cotton. The population consists of the native Sindis, with a large sprinkling of Beluchis and Afghans; the greater portion of them are Mohammedans of the Sunnite faith. The population are almost wholly engaged in agriculture. The trade of the province is concentrated at Karachi (q.v.), the capital. Raw cotton, wool, and various grains are the principal exports. Besides Karachi (pop. in 1921, 216,833) there are the large towns of Hyderabad (81,838), Shikarpur, Larkhana, and Sukkur.

In Sind, as in the Punjab, remains have been discovered of a Chalcolithic civilisation, showing affinities to those of Elam and Sumer, assigned to the 3d millennium B.C. At Mohenjo-daro excavations have disclosed a finely built city, with temples and houses of brick (kiln-burnt and sun-dried), terraces, courtyards, bathrooms, and elaborate drains, crude stone knives and scrapers, copper vessels, jewellery of gold, silver, carnelian and other stones, blue and white glazed faience, stone statues, and great numbers of engraved seals, 'in a style worthy of the best Mycenaean art.' These seals bear inscriptions which await decipherment. Under the city are remains of earlier cities, layer below layer.

About 712 A.D. Sind was conquered by Mohammed Kasim, the general of the khalif, and since that time has been almost entirely ruled by Mohammedan princes. About 871 the khalifs lost their hold upon this province, which became divided between the two native kingdoms of Multan and Mansura. In 1026 Sind was conquered by an officer of Mahmud of Ghazni, but the conquest was not at all a permanent one. A new native dynasty was founded in 1051, and was followed by others in 1351 and 1521. In 1592 the country was conquered by Akbar, the Mogul emperor of Delhi; and in 1739 it was incorporated in the dominions of Nadir Shah of Persia. Under Persian suzerainty Sind was governed by various native dynasties. The rulers of Sind always regarded the British with suspicion, and not without reason, for on the outbreak of the Afghan war in 1838 the British government forced the chiefs of Hyderabad and Khairpur to agree to a treaty which virtually destroyed their independence. And when their Beluchi subjects, resenting this arrangement, took up arms, Sir Charles Napier marched against them, totally routed them at Meeanee (17th February

1843), and at Dabo, near Hyderabad (24th March), and annexed their territories. The British administrators have directed their chief efforts to the development of the commerce of the country, principally by the construction of the Indus Valley Railway and the harbour-works at Karachi.

See five volumes by Sir R. Burton (1851-77), and gazetteers of the province by Hughe (1876), and Aitken (1907).

Sindia, the title of the Mahratta princes or rulers of Gwalior in India. The founder of the family was RANOJI SINDIA, who from a menial station in the household of the Peshwa rose to a high rank in the bodyguard, and after 1743 received in hereditary fief one-half of the extensive province of Malwa. His son, MADHAVA RAO (MADHOJI) SINDIA (1750-94), joined the Mahratta confederation, and was present at the battle of Panipat (1761), where he was so desperately injured as to be left for dead; but he recovered. In 1770, along with the Peshwa and Holkar, he aided the emperor of Delhi to expel the Sikhs from his territories, the administration of which was handed over to Sindia, thus making him the most powerful of the Mahratta chiefs. He first came into collision with the British in 1779; but in the war which followed fortune distributed her favours with impartiality, and by the treaty of Salbye (1783) Sindia was recognised as a sovereign prince and confirmed in all his possessions. In 1784 he captured the stronghold of Gwalior, and in the following year marched on Delhi, and subsequently seized Agra, Alighur, and nearly the whole of the Doab (q.v.). The manifold advantages of European discipline had struck him forcibly during the war with the British, and, with the aid of an able French officer, he raised and drilled an army of troops, with whom he reduced Jodhpur, Udaipur, and Jeypore, three Rajput states, and effectually humbled the pride of Holkar. See H. G. Keene's *Madhava Rao Sindia* ('Rulers of India' series, 1892).—DAULAT RAO SINDIA (1794-1827) continued his granduncle's policy, and during the troubles which convulsed Holkar's dominions at the commencement of the 19th century ravaged Indore and Poona, but was routed in 1802 by Holkar. Having joined the rajah of Berar in a raid on the Nizam (1803), he brought down upon himself the vengeance of the East India Company. The confederated Mahrattas were routed at Assaye and Argaum by Sir Arthur Wellesley, and were scattered irretrievably at Laswari by Lord Lake. Thereupon Sindia hastened to sign a treaty by which all his possessions in the Doab and along the right bank of the Jumna were ceded to the British. Gwalior was, however, restored in 1805, and from that time became the capital of Sindia's dominions.—During the reign of MUGAT (JANAKJI) RAO (1827-43), a minor, the Gwalior dominions were in such a state of anarchy that the British felt called upon to interfere; a war ensued, and the Mahrattas were routed at Maharajpūr (December 29, 1843) by Lord Gough, and at Panniar by Major-general Grey on the same day. Gwalior fell into the hands of the British, 4th January 1844, and Sindia submitted to the conditions demanded of him, besides maintaining a contingent force of sepoy at Gwalior. During the Mutiny BAJI RAO (1843-86), successor of Mugat, took the field against the Gwalior contingent, which had joined the rebels; but most of his troops deserted him during the battle (June 1), and he narrowly escaped by fleeing to Agra. He was subsequently reinstated by Sir Hugh Rose, and received from the British government substantial marks of its goodwill and approbation. He was succeeded by his adopted son in 1886, when the British cantonment was removed from Gwalior.

Sindibad. See SEVEN WISE MASTERS.

Sine. See TRIGONOMETRY.

Sin-eaters, a class of men formerly employed in Wales and on the Welsh border, in connection with funeral rites, to eat a piece of bread and drink a cup of ale placed on the bier, and so symbolically take upon themselves the sins of the deceased. As soon as this was done the sin-eater 'pronounced the ease and rest of the soul departed, for which he would pawn his own soul,' and so took his way, having freed the dead sinner from the necessity of walking an unquiet ghost. John Aubrey (q.v.) is chief authority for this custom in the 17th century, common then or earlier in Shropshire and Hereford as well as in Wales; but in 1852 it was described as having been regularly practised shortly before that date near Swansea. To many the name has been rendered familiar by the title of a volume of Fiona Macleod's interpretations of the sombre superstitions of the men of the Western Isles. The name may be due to a misinterpretation of Hosea, iv. 8—'They eat up the sin of my people;' and a parallel to the custom may be found in the Levitical 'scape-goat.' But Mr Sidney Hartland is inclined to see in sin-eating, and in the ceremonial use of certain suspicious funeral-cakes, biscuits, and draughts, prescribed by use and wont not merely amongst savage peoples but in India, in some parts of Russia, Germany, Greece, Italy, and France, as well as in Yorkshire, Shropshire, and Pembroke, the softened survival of a genuine cannibal feast at which the actual flesh of the deceased relative or friend was more or less solemnly consumed by the mourners. (See *The Legend of Perseus*, 1894-96.)

Sinecure, usually an office which has revenue without employment. In the canon law a sinecure is an ecclesiastical benefice, such as a chaplainry, canonry, or chantry, to which no cure of souls is attached, and where residence is not required. The strictest kind of sinecure is where the benefice is a donative, and is conferred by the patron expressly without cure of souls, the cure either not existing, or being committed to a vicar. Sinecure rectories were abolished in 1840. Sinecure offices were formerly very numerous in the English public service. They were used to enrich ministers of state and their families; Sir R. Walpole, for example, presented his son Horace to three or four sinecure places which brought him in a large income. The number of such places has been greatly diminished by modern reforms; the stewardship of the Chiltern Hundreds (q.v.) and some other offices of merely nominal profit are retained, because by accepting one of them a member of the House of Commons is enabled to vacate his seat.

The Norman crown took over some 1500 manors, townships, hundreds, honors, or baronies, which were administered first by bailiffs (*ballivi*) and afterwards by stewards (*senescalli*), whose function was to administer those areas as the sheriffs—to whom they were not subject—did the counties. They were eminently distinguished for extortion, and their powers were gradually curtailed. Under Charles II. it was resolved to discontinue as a rule the appointment of stewards of the manors, &c., and give to lessees the rights of the king as lord of the manor; a few stewardships, latterly some twenty, surviving down to modern times as honorary offices, presents to royal favourites. One was the Chiltern Hundreds, which, sold under the Commonwealth, reverted to the crown at the Restoration, and from 1679 to 1710 were leased, the rents being apparently treated as fee farm rents and the rights to them sold on that footing. A few rents are still paid to the crown, but since 1710 the remuneration, powers, and duties of stewards have

become trifling. The fictitious use of stewardships, as offices of profit under the crown, for enabling members of parliament to escape from posts they cannot resign, began in 1750, the grants being now made by the Chancellor of the Exchequer. Other stewardships than that of the Chiltern Hundreds that have been used in this way are those of Old Shoreham in Sussex (1756-99), East Hendred in Berks (1763-1840), Poyning in Sussex (1841-43), Hempholme in Yorks (1845-65), and—the only one besides the Chilterns now employed in this way—Northstead in Yorks, first used for parliamentary convenience in 1841. Escheatorships of Munster and of Ulster used to be taken advantage of in the same way. For perpetual pensions, see PENSIONS.

Sines, birthplace of Vasco da Gama, a small seaport on the Bay of Sines, at the south end of Portuguese Estremadura.

Sinestra, or VAL SINISTRA, a valley of the lower Engadine in the Swiss canton of Grisons, opening into the valley of the Inn, famous for a dozen mineral springs containing arsenic, iron, boric acid, lithium, iodine, and bromine.

Sinew. See TENDON.

Singakademie, a famous and influential choral society of Berlin founded in 1790 for the purpose of studying and practising choral music, 'not for the sake of amusement and pleasure, but with serious artistic aims.'

Si-ngan-fu (also spelt Sian, Si-gan-foo, Segan, and Hsi-an-fu), the capital of the Chinese province of Shen-si and a great administrative and commercial centre, was already well known to history in B.C. 2205 as 'the well-watered city' (owing to its wells). Under names as various as Wei-nan, Yung-chow, Kwan-nuy, Yung-ling, and Gan-se, its history extends continuously down to the present time from the days of the Chow dynasty, 1100 years before Christ, when it was already the capital of China; as it was in those of Shi-hwang-ti, the monarch who in 214 B.C. began the Great Wall. It was the centre of Nestorian influence in the 7th and 8th centuries of our era, as extant inscriptions yet testify; and Marco Polo knew it as Ken-jan-fu, then 'a place of great trade and industry.' The capital of the empire under at least three dynasties, it is even now one of the first cities in size, dignity, and importance. Its walls are almost as high and imposing as those of Peking; its four celebrated gates are handsomer and better fitted for defence. Admirably situated for trade, it stands near the Wei, the principal affluent of the Hoang-ho, where three great trade-routes radiate, on the great loess plateau that slopes southward and eastward from the high tablelands of Mongolia. Its position on the roads to Ili, Yarkand, and Kashgar gives it strategic importance, and many historical events have taken place around it. Its walls withstood several assaults of the Mohammedan rebels in 1868-71, and sustained a two years' continuous siege; but during the rebellion it suffered greatly, and has only of late completely recovered. During the operations in 1900 by foreign troops for the relief of the beleaguered legations in Peking, it was to Si-ngan-fu that the Dowager-Empress carried the Emperor and court for a time.

The streets of Si-ngan-fu are relatively wide, well-paved, and clean; the shops and warehouses are large and well-packed; silk, tea, and sugar are gathered hither and re-exported, being exchanged in Kan-sü, Turkestan, Kuldja, and Tibet for rhubarb and other drugs, musk, wool, and furs; and there is everywhere an appearance of energy, bustle, and prosperity. Of the population, which may amount to as much as a million, some 50,000 are Moham-

medans, and there are many Mongols, Tibetans, and other Asiatic foreigners.

The place is singularly rich in fine old temples and objects of antiquarian interest. Here are the oldest Moslem mosque in China, built more than 1100 years ago; a temple to Lao-tsze; 'the Forest of Tablets'—incised inscriptions (mostly Han dynasty), emblems, and historic scenes; a life-sized image of Confucius; the 'Thirteen Classics,' cut in stone under the Tang dynasty; and in the Manchu quarter or 'city' a palace site probably as old. But to westerners by far the most interesting relic is the large stone tablet, erected in 781 A.D., discovered by a native workman and re-erected in 1625, which bears in Chinese characters a record of the establishment of Christianity by Nestorians here in 635, and of the fortunes of the faith when other religions were making rapid headway. There is also a recapitulation of the story in Chinese verse. A Sino-Syriac inscription gives the date of the erection, and both in Estriangelo and Chinese characters are the names of many bishops, priests, and other personages, including the Nestorian patriarch of the time, the bishop or pope of China, and the mission staff in and about the city. There are in all nearly 2000 inscribed characters on the stone, which have been deciphered and read without much difficulty or uncertainty. The stone is a slab 9 feet high by 3 wide, and 1 thick. It stands (since 1907) in the Forest of Tablets. In that year the Danish traveller General Frits Holm obtained a replica, now in Rome, of the Chingchiaopei ('luminous worship monument') as it is called, of which he has given reproductions to many museums.

The progress, great extension, and ultimate decay of Nestorian missions in central and eastern Asia will be found in the article NESTORIUS, as also at GREEK CHURCH. In rumours as to the numbers and influence of the Nestorian Christians in these regions, reflected with odd distortions and exaggerations, we have perhaps to seek all that was historical in the earlier forms of the myth of Prester John (q.v.).

Singapore, a British dependency in Asia, the most important of the Straits Settlements (q.v.), consists of the island of Singapore (27 miles long, 14 broad; area, 217 sq. m.), separated from the southern extremity of the Malay Peninsula by a strait only half a mile wide at its narrowest, and of a great number of very small islands along its shores. In 1923, a causeway connecting Singapore with Johore was opened. The surface of the island is undulating, the highest point reaching 520 feet only. The climate is hot and moist, but the soil is not particularly fertile; nevertheless the island is perpetually clothed with verdure, and yields good crops of coffee, pine-apples, coconuts, aloes, and every kind of fruit, especially East Indian fruit (e.g. mango-steen and durian). Gambier, pepper, and nutmegs, formerly the staple crops, have been superseded by rubber. This island was purchased in 1824 from the sultan of Johore for £12,500 and a life-rent of £5000. Pop. of island (1881) 172,993; (1901) 228,555; (1921) 419,912.

The capital of the dependency, Singapore, is the only town on the island. It occupies a pleasant site on the south-east coast, on the Strait of Singapore, the principal waterway for vessels trading between eastern Asia and India and Europe. This city was founded by Sir Stamford Raffles in 1819 as an emporium for British trade in the East Indies, and it has since that time advanced and grown in prosperity till it has become the most important trading-place in the south-east of Asia, its only competitor being Batavia in Java, from which it is 600 miles distant. Singapore is a picturesque, well-built town, with

fine public buildings and all kinds of appliances in the nature of public works. It possesses a governor's residence, St Andrew's Protestant cathedral (1861-70), a Roman Catholic cathedral, Mohammedan mosques, Hindu temples, Chinese joss-houses, Raffles museum (1823), the supreme law-courts, post-office, hospitals, gaol, barracks, fine botanical and zoological gardens, a race-course, polo ground, &c. It is defended by numerous batteries and forts, and is a naval coaling station and dépôt. After the Great War further fortifications were built after considerable discussion and opposition. The harbour is spacious and safe and remarkably easy of access, while the dock accommodation is extremely extensive; the King's Dock (opened in 1913), 879 feet long, 100 feet wide, and 34 feet deep, is the largest east of Suez. It is a free port, no duties being levied except on petroleum, tobacco, spirits, wines, and beer. The annual trade of Singapore has increased at a remarkable rate since the city was founded. The total trade in 1823 was under £2,000,000; in 1851 about £4,000,000. The exports were valued at 7½ million pounds in 1887, at 27½ millions in 1910, and at 64½ millions in 1924; the imports were valued at 9½ millions in 1887, at 31½ millions in 1910, and at 74½ millions in 1924. Para rubber and tin account for two-thirds of the exports, while the chief imports are cotton piece goods, sugar, tobacco, rice, machinery, and coal. There is a considerable inter-settlement trade. Singapore is a port of call for passenger liners to the Far East. The population has grown at the same rate as the commerce. In 1824 the town had about 10,000 inhabitants; (1850) 50,000; (1881) 140,000; (1901) 200,000; (1921) 350,000, of whom two-thirds were males, mostly Chinese immigrants. The death-rate has been much reduced by sanitary and medical measures, especially in the matter of malaria. The climate, in spite of Singapore being situated little more than 1° N. of the equator, is uniform and agreeable, the nights being particularly cool and refreshing. The thermometer ranges between 67° and 94° F. and has a mean of about 82°. The rainfall varies from 65·6 to 92·2 inches in the year. There was a former town on the site of the present city, founded by Malay converts to Hinduism from Java to Sumatra, apparently in the 12th century; but it had wholly disappeared when Sir S. Raffles laid the foundations of the existing Singapore (i.e. 'Lion City'). It was made the capital of the Straits Settlements in 1830, superseding Penang.

Single-tax. See GEORGE (HENRY), TAX.

Sing Sing (officially since 1901, OSSINING), a village of New York, on the left bank of the Hudson (here 3 miles wide, and called Tappan Bay), 31 miles by rail N. of New York City. It contains many villas and a number of boarding-schools, and has some busy manufactories; but it is most widely known as the site of the large state-prison which rises from the bank of the river, and has been built since 1825. The Croton Aqueduct rests here on an arch of masonry with a span of 88 feet. Pop. (1920) 10,739.

Sinigaglia. See SENIGALLIA.

Sinister. See HERALDRY, and BATON-SINISTER.

Sin-kiang, or the 'New Dominion,' a great Chinese province formed by uniting Eastern Turkestan, Ili, Zungaria, and the western part of

Kansu. See articles under these heads. Area about 550,000 sq. m.; pop. 2,000,000 (Turks and Chinese); capital Urumtsi.

Sinking Fund, a fund formed by setting aside income every year to accumulate at interest for the purpose of paying off debt. A sinking fund for payment of the national debt of Britain was begun in 1716 by Sir Robert Walpole. Certain taxes which had been laid on for limited periods were then rendered perpetual, for the purpose of paying the interest of the funded debt. They produced more than enough for this purpose, and the surplus was laid aside, that it might accumulate into a fund for extinguishing the debt. It appeared to operate well, since, in 1728, after it had existed for twelve years, debt was wiped off to the extent of £6,648,000. It was not observed that, during the wiping off, new debt had been created to about the same extent, so that the nation was just in the position in which it would have been had it neither borrowed nor repaid. An historical experiment with a sinking fund was started in 1786 by the younger Pitt, who found himself faced by a National Debt of nearly 250 millions sterling. After executing a host of administrative and fiscal reforms, Pitt, influenced by the theories of a contemporary statistician, Dr Richard Price (q.v.), planned to have a surplus of one million sterling (afterwards increased) in the annual budget. This sum was to be handed over each year to a body of commissioners who should gradually buy over the debt and ultimately extinguish it. But in the French Wars budget surpluses gave place to deficits, and yet Pitt, anxious to maintain public confidence, retained the sinking fund, and borrowed the money to pay over to the commissioners. As this money was largely at a higher rate of interest than the debt it was meant to redeem, it followed that the sinking fund was only adding to the total debt. This burden continued to grow, and not till 1813 was the fallacy exposed. In that year Dr Robert Hamilton, in a treatise on the national debt, estimated the actual loss occasioned by the sinking fund at over 12½ millions sterling. Complications ensued when Vansittart borrowed from the sinking fund in 1820 and 1821. The whole scheme was condemned and eventually abandoned in 1829, when the Chancellor, Henry Goulbourn, established what has come to be called the 'old sinking fund' based on the annual realised surplus, if any. What was known as 'the new sinking fund' was started by Sir S. Northcote (Lord Idlesleigh) in 1875, the permanent charge for annual debt expenses being fixed at 28 millions. This sum was intentionally above that required, but any excess was to be used for debt redemption. Its working would therefore be cumulative, if further borrowing was not indulged in. But Northcote had to borrow and the fixed rule was not observed. The scheme was altered several times, but by 1914 had become of no effect, although the 'old sinking fund' remained legally valid. A Finance Act of 1923 abolished Northcote's scheme and established a new fund of a fixed amount to be devoted annually to debt redemption, the fund to be included in the yearly expenditure. It amounted to 60 million pounds in 1926-27. There are several other financial expedients similar in effect to the principal sinking funds, viz. terminable annuities, issues from the Consolidated Fund, payments for death duties, Conversion Loan sinking fund, Funding Loan sinking fund, Victory Bonds sinking fund, &c. See NATIONAL DEBT; and Nash, *Sinking Fund and Redemption Tables* (1884).

Sinn Fein. See GRIFFITH (ARTHUR), IRELAND (pp. 209-10).

Sinningia. See GLOXINIA.

Sinope (Turk. *Sinub*), a town of northern Anatolia, stands on a rocky tongue projecting into the Black Sea, 220 miles W. by N. of Trebizond. It has two harbours, one presenting the finest anchorage along the southern coast of the Black Sea. The town is surrounded by ancient Byzantine walls, and has a ruined castle built under Byzantine influence. The bay was the scene of a naval engagement on 30th November 1853, when a Turkish squadron was destroyed by the Russian fleet. The ancient city of Sinope was founded by a colony of Milesian Greeks, and for several years shared with Byzantium the supremacy of the Euxine. It was made by Pharnaces the capital of the kingdom of Pontus in 183 B.C. The great Mithradates, who was born within its walls, raised it to a lofty pitch of splendour. But in 72 B.C. it capitulated to Lucullus, and in 45 B.C. was made a Roman colony. After belonging successively to the empire of Trebizond (from 1204) and the Seljuks, it was conquered by the Turks in 1461. Sinope was the birthplace of Diogenes the cynic. Pop. 9000.

Sinter, the name given by German mineralogists to those rocks which are precipitated in a crystalline form from mineral waters. Sinter is of various forms, kidney-shaped, knotted, tuberous, botryoidal, tubular, stalactitic, shrub-like, or pronged, and is occasionally distinguished by its chief component, as Calc-sinter, Siliceous sinter, Iron-sinter, &c. Calc-sinter, which is a variety of carbonate of lime, composed of concentric plane parallel layers, appears under various forms; it is deposited with extraordinary rapidity by many springs, a peculiarity frequently made use of to obtain the incrustation of objects with a coating of this substance. Siliceous sinter is mostly found in intermittent hot springs, as in the Geysers (q.v.) of Iceland. Iron-sinter occurs in old mines and in coal-beds, where it is formed from iron pyrites through the agency of the atmosphere. The tubular conglomeration of grains of sand half-melted by lightning (*blitz*) is also known as Blitz-sinter, or Fulgurite (q.v.).

Sinus, in Anatomy, a term for the air cavities contained in the interior of certain bones—as the frontal, ethmoid, sphenoid, temporal, and superior maxillary. The frontal sinuses are two irregular cavities extending upwards and outwards, from their openings on each side of the nasal spine, between the inner and outer tables of the skull, and separated from one another by a thin bony septum. They are related to the prominences above the root of the nose called the superciliary ridges. They are not fully developed till after puberty, and vary considerably in size, being usually larger in men than in women and young persons. When very much developed they give a receding appearance to the forehead. They are larger in Europeans than in Negroes, and are very imperfectly developed in the Australians, whose peculiar want of vocal resonance is apparently due to this deficiency. They communicate on each side of the upper part of the nostril by a funnel-shaped opening, which transmits a prolongation of mucous membrane to line their interior. These sinuses are much more highly developed in certain mammals and birds than in man. Sir Richard Owen observes that 'they extend backwards over the top of the skull in the ruminant and some other quadrupeds, and penetrate the cores of the horns in oxen, sheep, and a few antelopes. The most remarkable development of air-sinuses in the mammalian class is presented by the elephant; the intellectual physiognomy of this huge quadruped being caused, as in the owl, not by the actual capacity of the brain-case, but by the enormous

extent of the pneumatic cellular structure between the outer and inner plates of the skull.' The sphenoidal sinuses are two large irregular cavities, formed, after the period of childhood, in the body of the sphenoid bone. They communicate with the upper part of the nose, from which they receive a layer of mucous membrane. Like the frontal sinuses, they serve to lessen the weight of the skull, and to add to the resonance of the voice. The ethmoid sinuses lie in the lateral masses of the ethmoid bone. They communicate with the cavities of the nose. Their main use is to diminish the weight of the forepart of the skull. That part of the temporal bone which forms the projection behind the ear is termed the *mastoid process*. The interior of this process is hollowed out with air-sinuses which communicate with the tympanum or middle ear, and through it with the nose. The superior maxillary sinus commonly known as the *Antrum of Highmore* (anatomist, 1613-84, who first accurately described it) is the largest of the sinuses, and the only one present in the infantile skull. Its uses are the same as those of the others, and, like them, it communicates with the nasal cavities.

The term sinus is also applied to certain channels for the transmission of venous blood. These are merely dilated veins formed by the separation of the layers of the dura-mater and lodged in grooves on the inner surfaces of the cranial bones. In Surgery the term *sinus* is nearly equivalent to *Fistula* (q.v.).

Sion, or **SITTEN**, capital of the Swiss canton of Valais, stands in a picturesque situation in the valley of the Rhone, 16 miles N.E. of Martigny by the Simplon Railway. It has a mediæval appearance, owing to three ruined castles perched on the crags above the town, and its cathedral, the church of a bishop since the 6th century. Pop. 6000.

Sion College, on the Victoria Embankment, London, was founded in 1623 as a college (though not for teaching purposes) and almshouse, on the site of a priory in London Wall, and the college was incorporated by charters of 1630 and 1664. In 1884 the almshouse became out-pensioners, and two years later the college with its fine theological library was transferred to the new building on the Embankment. The college was founded originally for the benefit of the clergy of the city and adjoining parishes, but in 1919 the membership was extended to several of the southern dioceses. For Sion House, see **ISLEWORTH**. See **Pearce**, *Sion College and Library* (1913).

Siout. See **SIUT**.

Sioux (pron. *Soo*), the principal tribe of the Dakota (i.e. 'confederate') family of American Indians (q.v.), now settled mostly in South Dakota and Nebraska. Forced by the Chippewas south and west, they made their first cession of lands to the United States government in 1830, and in 1837 ceded all their lands east of the Mississippi, and in 1849-51 those in Minnesota. For all these lands annuities were promised, which were, however, allowed to fall into arrears; and meanwhile the Indians were demoralised by the introduction of whisky. In 1862 a number of famishing men broke into a government warehouse, and so began a desperate war which desolated thousands of square miles of territory, cost a thousand whites their lives and the government \$40,000,000, and ended in the execution of the leaders. After some years of further disgraceful mismanagement and wrangling between the various government departments, the Santee Sioux were placed on a small reservation near Yankton, where they have developed into industrious and peaceful farmers. Meanwhile the hostile Sioux had retired to the northern parts of Dakota, where, under Sitting Bull, they gathered the young

braves who were exasperated by the government's failure to send supplies to the several agencies. The war which began and ended in 1876 is chiefly memorable for the disaster in which General Custer (q.v.) perished; it was ended in a few months, and Sitting Bull took refuge in Canada, but in 1880 was induced by the Dominion officials, on a promise of pardon, to surrender. The Brulé Sioux and the Ogallalla Sioux were afterwards settled on the Rosebud and Pinewood agencies in South Dakota. In 1890 there was a general rising of the Indians in the North-west, under a 'Messiah'; and in its course Sitting Bull was slain—whether killed in fight or slaughtered was questioned—on 15th December.

Sioux City, capital of Woodbury county, Iowa, on the east bank of the Missouri River (here crossed by a bridge 2000 feet long), 128 miles (by rail) above Omaha and 512 W. by N. of Chicago. It has good public buildings and schools, great stock-yards and packing-houses, machinery and electrical works, factories, mills, potteries, &c., and is the centre of a large agricultural and stock-raising district. Pop. (1880) 7366; (1900) 33,111; (1920) 71,227.

Sioux Falls, capital of Minnehaha county, South Dakota, and the largest town in the state, 241 miles by rail SW. of St Paul, is on the Big Sioux river, which here falls 90 feet, providing water power for flour mills and factories. There are several machine shops, and much quarrying is done. Here are several educational institutions. Pop. 25,200.

Siphon, a bent tube for drawing off liquid from one vessel to another. When in action the tube must be itself full of the liquid, so that the quantities of liquid in the two vessels form one continuous liquid mass. In accordance with the principles of Hydrodynamics (q.v.), there will be, in these circumstances, a flow of liquid along the tube until either the free surfaces of liquid in the two vessels are brought to the same level, or the one

vessel or the siphon becomes emptied of liquid. If it is desired merely to empty one vessel, a second vessel is not necessary. The principle on which the siphon acts will be readily seen by consideration of the figure. The two free surfaces are at the atmospheric pressure, but are at different levels. Take C at the same level as A. Then the pressure at A is obviously greater than the atmospheric pressure, while the pressure at C is less than the atmospheric pressure by the amount of pressure due to the column of liquid between C and the free surface in the lower vessel. Hence there must be a flow of liquid from A to C along the tube—i.e. from vessel to vessel. In the upper part of the siphon the liquid is sustained by the pressure of the atmosphere on the free surface, just as in the Barometer (q.v.). If then the siphon reaches higher above the free surface than the height of the barometer column of liquid used, the continuity of liquid will be broken at the bend, and the siphon will cease to act. Thus a siphon for water cannot be higher than 33 feet above the water surfaces; and a siphon for mercury is similarly limited to 30 inches. To bring it into working condition, a siphon is usually filled by suction applied (either by the mouth or by a pump) at the one end, the other end being immersed in the liquid; or it is first filled with the liquid and then placed in its proper position. In the general case, two vessels containing the

same liquid at different upper levels and connected by a filled siphon-tube will have the liquid flowing through the siphon-tube in the one direction or the other until the upper levels in the two vessels become the same, whatever the relative lengths of the siphon-arms; provided that this result be not rendered impossible by a breach in the continuity of inflow into the siphon, as where the free surface of the liquid comes to sink to the level of the inflow end of the siphon, whereupon air is drawn in and the flow ceases.

Siphonophora. See HYDROZOA.

Sippara. See BABYLONIA.

Sipunculus, a genus of worms belonging to the class Gephyrea. The body is cylindrical, unsegmented, without appendages or bristles, with tentacles around the mouth. The food-canal is spirally coiled, and ends anteriorly. The sexes are separate. A common species is *Sipunculus nudus*, which lives in the sand on the shores of the North Sea, the Atlantic, and the Mediterranean. It measures from 6 to 10 inches in length. The animal swallows the sand for the sake of the organic matter therein contained.

Sipylus, a mountain of Lydia, near Smyrna, with ancient rock-sculptures, showing Hittite influence, among them the figure of Niobe (q.v.).

Siquijor, an island of the Philippine group, 25 m. SW. of Bohol. The inhabitants raise coconuts, tobacco, maize, rice, and cocoa.

Sir (Fr. *sieur* and *sire*, contracted from *seigneur*; from Lat. *senior*, 'elder'), a term originally corresponding to *dominus* in Latin. It was at one time the practice to use the same title in addressing the clergy, a familiar instance being Sir Hugh Evans in the *Merry Wives of Windsor*. To so great an extent did this usage obtain that a 'Sir John' came to be a common sobriquet for a priest. 'Sir' was here a translation of *dominus*, the term used for a bachelor of arts, originally in contradistinction from the *magister*, or master of arts, but eventually extended to the clergy without distinction. Used along with the Christian name and surname, 'sir' is now applied exclusively to knights and baronets. Standing alone it is a common complimentary mode of address used without regard to rank. *Sire* is an older form of *sir*, formerly used in addressing royalty.

Sirach. See ECCLESIASTICUS.

Siracusa. See SYRACUSE.

Sirajganj, a town in Pabna district, Bengal, near the main branch of the Brahmaputra, 150 miles NE. of Calcutta. Pop. 25,000.

Sir-darya. See JAXARTES.

Siren, a genus of tailed Amphibians, represented by one species—*Siren lacertina*—living in swamps in the southern states of North America. The animal is eel-like, of a dark lead colour, one to two feet long, without hind-limbs, with four-toed weak fore-limbs, with three pairs of persistent external gills, with no teeth except on a small patch on the roof of the mouth. The food seems to consist of worms and insects.

Siren, an instrument which produces musical

sounds by introducing a regularly recurring discontinuity into an otherwise steady blast of air. Seebeck's siren consists of a large circular disk pierced with small holes at equal intervals apart in the same concentric circle. The disk is made to rotate more or less rapidly upon its axis; and while it is so rotating a nozzle, through which a strong blast of air is driven by means of a bellows, is brought to bear directly upon any desired circle of holes. When a hole is opposite the nozzle a puff of air escapes; when an unpierced portion of the disk comes before it the air is checked. Thus the blast of air is broken up into a succession of puffs, whose number per second is exactly equal to the number of holes which pass in front of the nozzle in one second. Knowing the rate of rotation per second of the disk and the number of holes in the circle that is being used, we can readily calculate the frequency of the musical note produced (see SOUND). By shifting the nozzle to bear upon a different circle of holes we get a different note for the same rate of rotation.

In Cagniard de Latour's siren the blast of air whose interruption gives the note also drives the siren. Fig. 1 shows the upper surface of the siren, SS, resting on the cover of the wind-chest, AA. In fig. 2 the instrument is shown in vertical section through the line *nn* of fig. 1. The blast enters by the pipe, BB. The cover of the wind-chest is pierced with exactly the same number

Fig. 1.

Fig. 2.

of holes as the disk, the only difference being that the holes pierced obliquely in both disk and wind-chest cover are oppositely directed in their obliqueness, as shown at *a* in fig. 2. When the corresponding holes are in apposition the blast of air is driven through all the holes, and by its impact on the obliquely cut walls of the holes in the disk forces the disk round. This brings the unpierced part of the disk opposite to the holes in the cover, and the air is cut off until the holes again come into apposition. The stronger the blast the more quickly will the disk be driven and the higher the note produced. A much more powerful tone can be obtained from this form of siren than from Seebeck's, inasmuch as all the holes are used simultaneously. Von Helmholtz's Double Siren is a combination of two of these on the same axis, each siren, by a suitable arrangement of concentric rings of holes which can be closed or opened at pleasure, being able to sound four distinct notes, singly or simultaneously. It is an invaluable instrument for demonstrating the laws of beats and combination tones (see SOUND). Other forms of siren used in fog-signalling are described under LIGHTHOUSE.

Sirenia, an order of aquatic mammals now represented by the dugong (*Halicore*) and the manatee (*Manatus*). Another form, Steller's sea-cow (*Rhytina stelleri*), was exterminated during

Siren lacertina:
a, head on larger scale.

the 18th century. In the Miocene and early Pliocene seas there seem to have been abundant Sirenians, many of which belonged to the genus *Halitherium*. As the dugong, the manatee, and Steller's sea cow (see RHYTINA) are described in separate articles, it is enough to state here that the Sirenians form a very distinct order, that in spite of their superficial resemblance they have certainly no near affinities with Cetaceans, that at present we must be content to regard them as old-fashioned and, it is to be feared, moribund types, occupying a lowly position in the Mammalian series. The name, which suggests mermaids, seems to refer to the appearance of the dugong, when it raises its head above the water or carries its young one under its arm.

Sirens, sea-nymphs in Greek Mythology who sat on the shores of an island between Circe's isle and Scylla, near the south-western coast of Italy, and sang with bewitching sweetness songs that allured the passing sailor to draw near, but only to meet with death. In Homer there are two, in later writers three, Ligeia, Leukosia, and Parthenope, or Aglaopheme, Molpe, and Thelxiepeia. If any seaman could resist the enticements of their magic music they themselves were doomed to die, but Ulysses or the Argonauts alone succeeded in doing so. In the *Odyssey* we read how Ulysses, by the advice of Circe, stopped the ears of his companions with wax, and lashed himself to a mast, until he had sailed out of hearing of the fatal songs. The Argonauts got safely past because Orpheus protected them by the stronger spell of his own singing, whereupon the sirens threw themselves into the sea and were transformed into rocks. The Latin poets give them wings, and in works of art they are often represented as birds with the faces of maidens, and are provided with musical instruments. According to J. P. Postgate (*Cambridge Journal of Philology*, vol. ix.), the original meaning of the word is 'bird.' In later days they are represented on tombs as singers of dirges for the dead, and more generally as symbolising the magic power of eloquence and song. Parallel conceptions are the Mermaid (q.v.) of western Europe and the Lorelei (q.v.) of the Rhine. See Miss Harrison's *Myths of the Odyssey in Art and Literature* (1881).

Sirhind, a tract in the Punjab, being the north-eastern part of the plain between the Jumna and the Sutlej, which is watered by the great Sirhind Canal (main branch finished in 1882) and its branches. Sirhind, which is not an administrative division, contains five British districts (one being Umballa) and nine native states (including Patiala). It is named from an ancient town in Patiala, now in ruins.

Sir-i-kol, a great lake of the Pamir (q.v.).

Sir-i-pul, a river, city (75 miles NE. of Maimana; pop. 15,000), and district in Afghan Turkestan.

Sirius, or the *Dog-star*, the brightest star in the heavens, is situated in the constellation *Canis Major*, and is visible in the winter months, being due south at midnight on the last day of the year. From its brightness the inference was made that Sirius was one of the nearer stars. By a comparison of its position about 1700 A.D. with that given in Ptolemy's Catalogue, 200 A.D., Halley found that it had a considerable proper motion, i.e. progressive motion relative to neighbouring stars, and this confirmed the view that Sirius was comparatively near. Many attempts were made to measure its distance. At length they were successful, and its distance has now been found to be 540,000 times that of the sun, or 50 million million miles. This is correct to within 5 per cent. The luminosity of Sirius is thirty times that of the

sun, i.e. it emits thirty times as much light, and at an equal distance would appear thirty times as bright as the sun. It is a blue star, of spectral type A₀, and its 'effective temperature,' which may be roughly defined as that near its surface, is about 11,000° C, about double that of the sun. In 1844 Bessel found that Sirius has a small oscillatory motion which he attributed to its revolution around an invisible companion. This was confirmed by other astronomers, and Auwers found that the period of this revolution was fifty years. In 1862 Alvan Clark, while testing a large object glass, detected a faint star at an angular distance of 7" from Sirius. This proved to be the till then invisible companion. Since this date the companion has been followed in some of the largest telescopes, and the period of revolution of fifty years verified. As the centre of gravity of the system should have no oscillatory but only progressive motion, it has been possible to calculate its position. Further, from the measured angular distance the linear distance between the two bodies can be calculated, and is found to be twenty times that of the earth from the sun. From these data the mass of Sirius has been calculated as 23 times that of the sun, and that of the faint companion as 1.0 of the sun. The light emitted by Sirius is 17,000 times the amount from the faint companion. It follows that the faint companion must have very low surface luminosity, or must be of small size. Spectroscopic observation shows that the companion is of high surface luminosity, and, attributing its faintness to its small size, its diameter is found by Eddington to be only 25,000 miles, while that of Sirius is 1,500,000 miles. This small size implies a density of 53,000 times that of water. Such a density seems at first sight incredible, but is explained by Eddington on the modern theory of the constitution of matter in which an atom consists of a nucleus round which electrons are circulating as the planets circulate round the sun. The compression of ordinary matter can only be pushed to the extent of bringing these miniature planetary systems into contact. But at the high temperatures inside stars, elections are stripped from their nuclei, and compression to a much greater extent is possible. Eddington pointed out that the small size and high density of the companion of Sirius admitted of verification on the theory of relativity. In the sun the lines of the spectrum are shifted slightly towards the red, and a similar shift, but of considerably greater amount, owing to the greatly increased force of gravity at the surface, was to be expected. This extremely difficult observation was carried out by Adams with the 100-inch telescope at the Mount Wilson Observatory, and the displacement predicted by Eddington was confirmed.

Sirocco (Ital. *Scirocco*), a dust-laden dry wind coming over sea from Africa; but also applied to any south wind, often moist and warm, as opposed to the Tramontana or north wind, from the hills. See STORMS.

Sisal-hemp, or HENEQUEN, a fibre got from the leaves of certain species of Agave (q.v.).—*A. fourcroydes*, *A. sisalana*, *A. Cantala*—introduced into commerce in Mexico in 1839, and named from the small port of Sisal in Yucatán, whence it was first exported. Besides Mexico, Central and South America, the West Indies and Bahamas, it is now grown in East Africa, India, Indo-China, and the Philippines. The fibre, removed by machinery, is in strands of 3 to 5 feet long, nearly white, stronger and woodier than hemp.

Siskin (*Chrysomitris*), a genus of perching birds belonging to the family Fringillidæ, the true finches. The best-known species is the Common

Siskin (*C. spinus*), which occurs from Britain eastward to Japan. This species breeds in the centre and north-east of Scotland, and is a familiar winter visitor to England and Wales. It is also common in some parts of Ireland. The siskin usually builds its nest, which is made of twigs

Siskin (*Chrysomitris spinus*).

and roots lined with moss, high in the branches of fir and birch trees. Two broods are reared in a season. The prevailing colour is yellowish green, with yellow and black markings on the upper and white on the under surface: the female being dingier than the male. The siskin is a common cage-bird.

Sisley, ALFRED (1839-99), French painter, was born in Paris, his family being of British origin. Poverty and ill-success were his lot during his lifetime, but now his position as an able exponent of Impressionism (q.v.) is secured. His art is essentially intimate, his landscapes being full of spontaneity and charm.

Sismondi, JEAN CHARLES LÉONARD SIMONDE DE, a historian of Italian descent, was born at Geneva on 9th May 1773. The French Revolution drove the family first to England and then to farm-work in Italy; but in 1800 Sismondi himself went back to Geneva, and, having obtained certain municipal offices, applied himself to his favourite literary pursuits. He was introduced to Madame de Staël, and became one of the intimates of her circle, like Benjamin Constant and Schlegel. Whilst in the company of this lady he formed the beginning of a fast friendship with the celebrated Countess of Albany, widow of the Pretender and mistress of Alfieri. His *Histoire des Républiques Italiennes du Moyen-Âge* (16 vols. 1807-18) placed him in the first rank among contemporary historians. The events of the Hundred Days brought about one of the most memorable passages in his life—an interview with Napoleon. In 1813 appeared his *Littérature du Midi de l'Europe* (Eng. by Roscoe); and in 1819 he began his second great work, *Histoire des Français*, with which he was occupied until his death. As a historian Sismondi was distinguished more for industry than for natural gifts or graces of style. He took a lifelong interest in political economy: his first book on this subject, *De la Richesse Commerciale* (1803), is written from the standpoint of the *Wealth of Nations*; but in a later book, *Nouveaux Principes d'Économie Politique* (1819), he modified his views so far as to adopt a more decidedly moral or socialistic attitude. Amongst other products of his unwearying industry and perseverance may be named *Histoire de la Renaissance de la Liberté en Italie* (2 vols. 1832), *Histoire de la Chute de l'Empire Romain* (2 vols. 1835), and an abridgment (1839) of the twenty-nine volumes of his *Histoire des Français*. Sismondi died at Chêne near Geneva on 25th June 1842.

See *Vie et Travaux de Sismondi* (Paris, 1845); Sainte-Beuve's *Nouveaux Lundis* (vol. vi.); and collections of his own *Lettres Inédites* (1863 and 1878).

Sissoo Wood. See ROSEWOOD.

Sisterhoods, in the common sense of the word are those communities which are not enclosed, and whose life is one of active labour. St Vincent de Paul founded in 1633, assisted by Madame Le Gras, the first superior, the Society of 'Filles de la Charité,' and so laid the foundation of all modern religious communities who lead an active life devoted to various works of charity. The great need of such a society had become so obvious that the holy see, which had hitherto discouraged every attempt of a kindred character, solemnly approved of 'The Daughters of Charity' in 1655. In their constitution it was enacted that the community was 'to consist of girls, and widows unencumbered with children, destined to seek out the poor in the alleys and streets of cities.' In their founder's words, they were 'to have for monastery the houses of the sick; for cell, a hired room; for their chapel, the parish church; for their cloister, the streets of the town or wards of the hospital; for enclosure, obedience; for grating, the fear of God; for veil, holy modesty.' The order spread with wonderful rapidity over the world. After five years' probation the sisters take vows, renewable every year; their habit is gray-blue cloth, with large white collar, and white *cornette* for the head.

The 'Petites Sœurs des Pauvres' were founded in 1840 at St Servan, in Brittany, by the Abbé le Pailleur and Marie Jamet (1820-93), a poor needle-woman. The institute, formed for the care of the aged, destitute, and sick poor, is still in great measure supported by scraps of food and other alms which the sisters beg day by day from house to house. The 'Sœurs de Bon Secours' (of Troyes) were also founded in 1840, by Abbé Miller, canon of the cathedral at Troyes, for the purpose of nursing the sick in their own homes. Another order of 'Bon Secours' Sisters (of Notre Dame) was founded in 1824 by Archbishop Quélen. A heroic sisterhood was formed in 1868 by Cardinal Lavigne, called 'of the African Mission,' for the care of Arab orphans and the reception and education of negro children rescued from slave-dealers.

After France, Ireland has by far taken the lead, both in the rapid growth of such societies and in the number of women she has given to the work. During the prevalence of the penal laws in Ireland it was impossible for a woman in the dress of a sister to be seen in the streets. But on their repeal in 1782 and 1793 the fire of charitable enthusiasm in Irishwomen broke out and spread the more rapidly for its long repression. The 'Irish Sisters of Charity' were founded in Dublin in 1815 by Mary Aikenhead, daughter of a gentleman of good Scottish family who had settled in Cork. The society is on the same lines as that of St Vincent de Paul, but entirely distinct from it, and the sisters are occupied in almost every kind of charitable work— orphanages, hospitals, penitentiaries, schools, convalescent homes, blind asylums, and certified industrial schools for girls under government. The other great sisterhood in Ireland is that of the Sisters of Mercy, founded in 1831 in Dublin by Catharine McAuley. The object of this institute is 'all works of mercy, corporal and spiritual, especially education.'

Of sisterhoods belonging to the Anglican communion the first foundation was made in 1845 by Dr Pusey and Lord John Manners (afterwards Duke of Rutland), who, assisted by a few friends, opened a small house in Albany Street, Regent's Park, to receive a few women desiring to devote themselves to charitable works. The sister of Lord Inchiquin gave a powerful impulse to the movement, and now the Sisters of Mercy are engaged in all kinds of charitable works—missions in the worst parts of London, schools both for the

poor and for others, convalescent hospitals—and have houses in various parts of England. Other sisterhoods are the Sisters of the Poor, founded in 1851, of St Margaret's (1854), founded by Dr Neale (q.v.), of the Holy Cross (1857), of St Peter's (1861), of the Church (1870) at Kilburn; and there are a large number of smaller sisterhoods in England.

The first Protestant sisterhood in America was organised in 1852 by Mr Muhlenberg, New York, and took charge of St Luke's Hospital, founded in 1859. Since then organisations of the kind have multiplied, the later ones following very closely the Roman Catholic model.

See MONACHISM, NUNS, and for Protestant Deaconesses, DEACON.

Sistine Chapel, so called as having been built for Sixtus IV. in 1473–81, is the private chapel of the popes in the Vatican, and is the scene of the great religious ceremonies at which the pope in person assists. It is an apartment 133 feet long by 43 feet wide, the height being greater than the width, and was designed by the Florentine architect Giovanni de' Dolci. The screen separating the congregation from the area reserved for pope and cardinals is a specimen of magnificent Renaissance marble decoration, and so is the tribune for the singers; but the main glory of the building lies in the frescoes with which the walls and ceiling are covered. Six subjects from the life of Moses occupy one wall, and six scenes from the life of Christ the opposite one, painted by the best Tuscan and Umbrian masters—Botticelli, Roselli, Ghirlandajo, Signorelli, Pinturicchio, Perugino—but Michelangelo's 'Creation,' 'History of Noah,' 'Prophets,' 'Sibyls,' on the ceiling, and his stupendous 'Last Judgment' on the altar wall, are specially noteworthy. The floor is adorned with a marble pavement in the 'Cosmatesque' style; and beneath the frescoes the marvellous tapestries of Raphael used on great occasions to be displayed. The celebrated Sistine Chapel choir of men's voices, founded by Gregory the Great, sings without instrumental accompaniment in a style that has long been famous throughout the world.

Sistova (Bulg. *Svišov*), a town of Bulgaria, on the south bank of the Danube, about 35 miles above Rustchuk. It carries on tanning, cotton-weaving, and wine-growing, and does a large trade in cereals. Here peace between Austria and Turkey was concluded in 1791; the Russians burned the place in 1810, and crossed the Danube into Bulgaria close by in 1877. Pop. (1920) 11,847.

Sistrum, a wire rattle used in ancient Egyptian religious ceremonies. See EGYPT, fig. 9.

Sisymbrium. See HEDGE-MUSTARD, ROCKET.

Sisyphus, in Greek Mythology, son of Æolus, father of Glaucus, and husband of the Pleiad Merope; only in post-Homeric legends, from his cunning, the father of Odysseus. He is said to have been founder and king of Ephyra, afterwards Corinth, and both he and his whole house were notorious for their wickedness. Homer does not give the reason for his punishment in the lower world, but some later accounts make it his disclosure to the river-god Asopus that it was Zeus who had carried off his daughter; others, his wholesale robbery and murder of travellers. He was condemned to roll an immense stone from the bottom to the summit of a hill, which, whenever it reached the top, rolled down again, and so the task of Sisyphus had to be begun anew.

Sitapur, a municipality with (1921) 21,584 inhabitants in Oudh, 52 miles NW. of Lucknow. The place has a cantonment, and is the headquarters of a district in the Lucknow division of Oudh.

Sitka, the former capital of Alaska, is on the west coast of Baranof Island, a deep harbour dotted with islands in front, and snow-clad mountains rising behind. Its principal buildings are the Greek church and the old Russian palace. Pop. 1200.

Sitten. See SION.

Sittingbourne, a brick-making market-town of Kent, on Milton Creek, 11 miles ESE. of Chatham and 45 of London. In olden days it was a great halting-place for Canterbury pilgrims and for kings and others on their way to the Continent. Pop. (1921) 9340.

Sitting-Bull (1837–90). See SIOUX.

Sitwell, a family of genius, the daughter and sons of Sir George Sitwell, who, born in London in 1860, was educated at Eton and Christ Church, Cambridge, sat in parliament for Scarborough (1885–6, 1892–5), and is best known as the biographer of William Sacheverell (*The First Whig*, 1894). EDITH SITWELL, born at Scarborough, was educated privately. She edited *Wheels* (1916–21), an annual anthology of new modes of verse. Her own volumes are *The Mother and Other Poems* (1915), *Clowns' Houses* (1918), *The Wooden Pegasus* (1920), *Children's Tales* (1920), *Bucolic Comedies* (1923), *Sleeping Beauty*, *Troy Park* (1925), *Elegy on Dead Fashion* (1926). In imagination Miss Sitwell is of the kindred of Blake and Keats, but the new world she introduces her readers to is expressed in terms of a new notation, difficult by its newness—a beautiful world, seen by flashes, kaleidoscopic rather than coherent, yet apparently quite a valid world. As a verse technician her touch is certain. *Twentieth Century Harlequinade and Other Poems* (1916) is a joint work of Edith Sitwell and her brother OSBERT SITWELL, who was born in London in 1892, was educated at Eton, and in 1913–19 served in the Grenadier Guards. His own works in poetry, satire, fiction, and criticism—*Argonaut and Juggernaut*, *The Winstonburg Line* (1919), *Who Killed Cock Robin?* (1921), *Out of the Flame* (1923), *Triple Fugue* (1924), *Discussions on Travel, Art, and Life* (1925), *Before the Bombardment* (1926), show satirical and descriptive power and wit. The younger brother, SACHEVERELL SITWELL, born at Scarborough in 1900, and educated at Eton and Balliol, has interested himself in the culture and art of 18th-century Italy, and shows a faculty of seeing, fantasy, and a vivid style in *The People's Palace* (1918), *The Hundred and One Harlequins* (1922), *Southern Baroque Art* (1923), *The Thirteenth Caesar* (1924), *Exalt the Eglantine and Other Poems* (1926), *All Summer in a Day: An Autobiographical Fantasia* (1926).

Sium. See SKIRRET.

Siut, or ASSIUT, as it is now called, the chief city of Upper Egypt, stands on the west bank of the Nile, about 200 miles by rail from Cairo. It has some fine mosques, an American mission-school and hospital, a European hotel, and well-built dwelling-houses. The inhabitants are chiefly Copts. The population is about 51,000 in number, mostly traders, and there are local manufactures of polished red and black earthenware, ostrich-feather fans, carved ivory, and scarves woven with silver. There is a certain amount of trade with Darfur and Senaar. Assiut stands on the site of the town which the ancient Egyptians called Siut, and still retains its ancient name with the addition of the Arabic definite article. The Greeks knew the city as Lycopolis, the Town of the Wolf, from the animal which was worshipped there. Very little remains of the Greco-Egyptian town; but in the cliffs, at the foot of which the town stands, there are many rock-hewn tombs of nobles of the XIth

and XIIIth dynasties; among others is the tomb of Hepzefa, with the famous inscriptions of the endowments to the priests of the temple of Siut for services to be performed for his benefit after his death. From the top of the cliffs there is a fine view over the valley of the Nile.

Siva (a Sanskrit word, literally meaning 'happy,' 'auspicious') is the name of the third god of the Hindu Trimūrti (q.v.) or triad, in which he represents the characters both of Destroyer and Reproducer. The name Siva, as that of a deity, is unknown in the Vedic hymns, but established as such in the epic poems, Purāṇas and Tantras. The *Saivas*, or worshippers of Siva, assign to him the first place in the Trimūrti; and to them he is not only the chief deity, but the deity which comprises in itself all other deities. Thus, in the *Siva-Purāṇa*, he is addressed as Brahmā, Viṣṇu, Indra, Varuṇa, as the sun and the moon, as earth, fire, water, wind, &c.; but even in the Purāṇas relating to Viṣṇu his power is exalted in praise, and he is addressed with the utmost awe. Siva is doubtless a combination of an Aryan god, Rudra the lord of the storm which brings death as well as healing, and a non-Aryan deity of pastoral life—his phallic attributes being doubtless derived from the pre-Aryan indigenous belief. The symbol of Siva is the Linga (q.v.), emblematic of creation, which follows destruction. From each of his numerous attributes or characteristics he derives a name or epithet. He has five heads (hence his name *Pañcādhana*, 'the five-faced'); three eyes (hence his name, *Trinetra*, &c., 'the three-eyed'), one of which is on his forehead, and indicates his power of contemplation; and in the middle of his forehead he wears a crescent. His hair is clotted together, and brought over the head so as to project like a horn from the forehead. On his head he carries the Ganges, whose course he intercepted by his hair, when this river descended from heaven, so as to enable the earth to bear its fall. Round his neck he carries a garland of human skulls. In his hands he holds the trident, a club or pole, aimed at the upper end with transverse pieces, representing the breastbone and ribs adjoining, and surmounted by a skull and one or two human heads. Among his weapons are a bow, a thunderbolt, and an axe. As the destroyer of the world, he is also called *Kāla* ('Time' or 'Death'), and represented as of black colour. One of his representations is also half-male and half-female, emblematic of the indissoluble unity of the creative principle. He is clothed in a deer-skin; or he also holds a deer in one of his hands; or he sits on a tiger-skin, or is clothed in it. When he rides, the bull Nandi is his beast of burden, whom he also carries as an emblem in his banner. He resides on the wonderful mount Kailāsa, the northern peak of the Himālaya, where he also rules over the north-east quarter. His principal wife is variously called Devī, Durgā, Umā, and Kālī, and is the great goddess of modern worship; she delights in human sacrifice (see THUGS), and her character is clearly derived from the pre-Aryan worship of a great goddess of the life of nature and fertility; she is practically unknown to the Vedic literature. One of his chief attendants is Tanḍu, who is one of the original teachers of the arts of dancing and mimicry, whence Siva is the patron of dancers. Besides Tanḍu, a host of other attendants and companions, together with demons and other beings, surrounding him, are named by the Purāṇas. Amongst the principal achievements of this god is his conflict with the god Brahmā, who was originally possessed of five heads, but lost one through exciting the anger of Siva by disrespectfully addressing him. Siva is especially worshipped under the symbol of the Linga; but there are

periods at which homage is paid to him also under other forms, corresponding with the description given above. Siva and Viṣṇu are nowadays in their male and female forms practically the gods of the Hindu population. Like Viṣṇu, Siva has a thousand names by which he is addressed; some derived from his exterior attributes have been mentioned before; among the others the principal are *Īśa* or *Īśvara*, 'lord'; *Maheśa* or *Maheśvara*, 'the great lord'; *Śankara*, 'the conferrer of happiness'; *Rudra*, 'the terrible,' or *Mahārudra*, 'the very terrible'; and *Mahādeva*, 'the great god.' See INDIA, Vol. VI. p. 106.

Sivaji (1627-80), the founder of the Mahratta power in India. See MAHRATTAS.

Sivas, a city of Anatolia, is situated on the Kizil Irmak (anc. *Halys*), 170 miles SW. of Trebizond, and is a dirty, decayed place. Pop. 35,000. It is built on the site of the ancient *Sebasteia*, from which it derives its name.

Siwa. See AMMON, OASES.

Siwalik Hills. See HIMALAYA, Vol. V. p. 715.

Siwash, or PUTRID SEA. See CRIMEA.

Six Acts, six repressive measures passed in England in 1819 to prevent seditious assemblies and unauthorised military training, punish seditious libels, increase the power of the magistrates, and further restrict the liberty of the press. They were very unpopular, and are known as the 'Gagging Acts.'

Six Articles, STATUTE OF, an enactment of Henry VIII. (1539), commonly called the Bloody Statute, to compel the uniform profession of the following six doctrines: (1) The Real Presence of Christ in the Eucharist, and Transubstantiation; (2) the sufficiency of communion in one kind only; (3) the unlawfulness of the marriage of priests; (4) the obligation of vows of chastity; (5) the propriety of retaining private masses; (6) the expediency and necessity of auricular confession. In spite of the threatened penalties, only twenty-eight persons suffered death under the statute throughout the whole reign. See HENRY VIII.

Six Nations. See IROQUOIS.

Sixtus, the name of five popes, of whom two call for particular notice, Sixtus IV. and Sixtus V. The former (originally named Francesco della Rovere), born July 22, 1414, was the son of a fisherman in Celle, a small village near Savona. He was a pupil and friend of the celebrated Cardinal Bessarion, and, having entered the Franciscan order, gained the highest reputation throughout Italy as a preacher. On the death of Paul II. in 1471, Rovere, who had risen to be general of his order, was elected to the Roman see. His inordinate partiality for his relatives exhausted the papal treasury, and led to many questionable exactions, and to gross abuses in the dispensation of church patronage. But the worst imputation upon his memory is his connivance in the Pazzi conspiracy against the Medici (q.v.) at Florence. In many respects, however, his administration was liberal and public spirited. He did much to foster learning and to encourage art, and contributed notably to the improvement and decoration of the city. He built the Sistine chapel and the Sistine bridge across the Tiber, took a zealous interest in augmenting the Vatican library, and was a munificent patron of the great painters of the day. In 1482 he entered into an alliance with the Venetians against the Duke of Ferrara, which led to a general Italian war, and ended in a dissolution of the Venetian alliance, an event so mortifying to the pope that his death is said to have been caused by chagrin, August 13, 1484. His successor was Innocent VIII.—SIXTUS V., one of the most able

and vigorous occupants of the Roman see, originally named Felice Peretti, was born (December 13, 1521) near Montalto, of poor parents. He early entered the Franciscan order, was ordained at Siena in 1547, won a great name as an eloquent preacher, and gradually rose, through the offices of inquisitor-general in Venice and vicar-general of the Franciscan order, to be cardinal (Cardinal Montalto) in 1570. Shortly after the accession of Gregory XIII. (1572) he began to lead a retired and studious life, but after this period of forced inactivity, was elected successor to Gregory in 1585. The rule of Sixtus was most active and energetic, and was marked by vigorous measures of improvement in every department of administration, ecclesiastical as well as civil. His first care was to repress the prevailing license and disorder of the city of Rome, and of the papal states generally, by breaking up the bands of outlaws by which both were infested. He reformed the administration of the law and the disposal of public patronage; and he entered upon numerous projects for the moral and material improvement of Rome. He erected the library buildings of the Vatican, built the Lateran Palace, finished the Quirinal, besides restoring and rebuilding many churches. He found an empty pontifical treasury; yet by judicious retrenchment and heavy taxation he secured within the first years of his short pontificate a surplus of some 5 millions of crowns. To the Jews (q.v.) he extended full liberty to trade and celebrate their own worship throughout his dominions. The great aim of his foreign policy was to advance the cause of the Roman Catholic Church in every quarter of Christendom, against the Huguenots in France, against the Lutherans in Germany, and against Queen Elizabeth in England. At the same time he entertained a deep jealousy and apprehension of the designs of Spain. Amongst other reforms in church matters he fixed the number of the College of Cardinals at seventy, and reorganised the separate congregations of cardinals. Under his authority were published a new edition of the Septuagint and an edition of the Vulgate, the latter famous from the multiplicity of its errors, subsequently corrected in the edition of Clement VIII. Sixtus died on 27th August 1590, and was followed in the papal chair by Urban VII.

Many of the popular stories regarding him are derived from Gregorio Leti's *Vita di Sisto V.* (2 vols. Lausanne, 1669), a work of no authority. See the general works of Ranke and Gregorovius; also Tempesti, *Storia della Vita e Gestì di Sisto V.* (2 vols. Rome, 1754); Lorentz, *Sixtus V. und seine Zeit* (Mainz, 1852); and Baron Hübner, *Sisto V.* (Paris, 1870; Eng. trans. 1872).

Sizar, the name of an order of students at Cambridge and Dublin universities, so called from the allowance of victuals (*size*) made to them from the college buttery. Duties of a somewhat menial kind, such as waiting upon the fellows at table, were originally required of the sizars, but these have long since gone into disuse. At Oxford there was formerly a somewhat similar order of students denominated Servitors.

Size. See GLUE, and GELATINE.

Skagen, CAPE, or THE SKAW, the most northerly point of Jutland, with a lighthouse 148 feet high, and the small port of Skagen.

Skager-Rak, an arm of the North Sea lying between Denmark and Norway, and connecting with the Kattegat, is 140 miles by 70. The depth is much greater on the Norwegian coast (200 fathoms), where the current runs west, than on the Danish (30 to 40 fathoms; easterly current).

Skagway, a port in the part of southern Alaska which was claimed by Canada but in 1901

awarded by the Commission to the United States, at the mouth of the Skagway River and the head of the Lynn Canal. It was settled in 1897 during the Klondike gold-ush, but afterwards declined in importance. Pop. 800.

Skald signifies in old Norse a poet. The name was given specially to that class of poets who exercised their art as a vocation requiring a learned education—i.e. a knowledge of the construction of verse, and of the enigmatical imagery, roughly shaped out of obscure tradition, to which Scandinavian poets were prone. The principal aim of the Skaldic poetry was to celebrate the deeds of living warriors or of their ancestors. Very few complete Skaldic poems are extant; but there are a great number of fragments preserved, partly in the younger Edda (q.v.), partly in the Sagas and the Heimskringla. See SNORRI STURLASON.

Skat, a game played with thirty-two cards as in Piquet (q.v.), and said to have been invented in 1817 in Altenburg, whence it rapidly spread into other parts of Germany and beyond the borders of the fatherland. Each of three players receives ten cards, the two others being laid aside (hence the name—from old French *escart*, 'laying aside'). The values of the cards and the rules of the game are expounded in numerous works.

Skate, the popular name of several species of Ray (q.v.). The Common Skate (*Raja batis*), known in Scotland as the *Gray Skate* and in the south of England as the *Tinker*, is plentiful on most parts of the British coasts. The Burton Skate (*R. marginata*) is another of the British species. On American coasts numerous species occur—e.g. on the east, the 'Tobacco-box' Skate (*R. erinacea*), the Briar-skate (*R. eglanteria*), the Smooth or Barn-door Skate (*R. laevis*); on the west, *R. inornata*, and the large *R. binoculata*, which attains a length of 6 feet. But a revision of the species of skate is necessary. Skates are voracious fishes, feeding along the bottom. Their egg-cases or mermaids' purses are often thrown up on the beach. They are often caught on the

Common Skate (*Raja batis*).

lines, but great numbers are now brought to market by the trawlers. The greatly expanded pectoral fins are eaten, but the flesh tends to be coarse.

Skating. Progression on ice is accomplished by means of instruments composed of steel blades which are fastened to the soles of the boot, and which are called skates. In early times the shin bones of animals were bound to the feet, and skaters glided over the frozen surface on these by propelling themselves with the aid of a spiked stick. At a later period the iron or steel blades were introduced, the cutting edge of which enabled the wearer to dispense with the stick, and to push off with one foot and glide on the other with alternate strokes. In England the Fen country, owing to the relative frequency of ice in that district, became the great home of skating. Now skating, both speed and figure, is an organised sport in Britain as throughout Europe and in North America. In Britain the ruling body of the sport is the National Skating

Association founded at Cambridge in 1879 and transferred to London in 1894. Internationally the International Skating Union, founded in 1892, is the governing body of international amateur skating.

Skates are now of three kinds—viz. those made for speed-skating, those for figure-skating, and those for games played on skates. A skate for general use may be had, and is satisfactory, though in any particular branch the specialised skate necessarily remains the best. Skates were formerly constructed by inserting the steel blade into a wooden bed, which was approximately shaped to the foot and bound to it by means of leather straps. Modern skates are made entirely of metal, and are fixed either by screws passing through plates (to which the blade is attached) into the sole of the boot, or they are fixed to the boot by various mechanical devices which enable the skate to be quickly and firmly attached, and as quickly removed.

The blades of skates for speed-skating are made very thin, about $\frac{1}{16}$ th of an inch, somewhat longer than the foot, and very slightly convex along the whole length of that part of the blade which comes in contact with the ice. The blades are now most often set in tubes, while the foot rests also on tubular supports, lightness, speed, and strength being thus at one and the same time secured. Races on skates are brought off on tracks having, over the longer distances, one or more turns. Some fastest times (all on straight courses) are: 500 metres (547 yd.)—43 $\frac{1}{2}$ sec., by O. Mathiesen (Norway), at Davos, 17th January 1914; 1000 metres (1093 yd.)—1 min. 31 $\frac{1}{2}$ sec., by O. Mathiesen, at Davos, 31st January 1909; 1 mile (with the wind)—2 min. 27 $\frac{1}{2}$ sec., by F. W. Dix (England), at Cowbit, Lincolnshire, 6th February 1912; 1 mile (without the wind)—2 min. 36 sec., by J. Nilsson (United States), in the United States, 1895.

Skates for figure-skating are generally solid in their several parts, the tubular pattern not here being in vogue. Their blades, as distinct from the blades of speed-skates, are broader and deeper, rounded at both toe and heel, and (to facilitate the making of turns and curves) with a curvature along the whole length equal to that of a circle having a radius of from five to seven feet. The Edinburgh Skating Club (1642) is the oldest club for encouraging figure-skating in Britain, but the figures skated were of an elementary character until after the formation of the Skating Club, London (1830), whose 'Skating Club Figures' induced a mode of skating peculiar to Great Britain. The mode is known as the 'English style' and consists of large and bold curves and turns, executed with power and quietness, while the body of the skater is held upright, and the knee of the travelling leg kept quite straight. In distinction from it is the 'international style,' a style, except in Britain, followed everywhere. Its basal feature is an absence of repression, a complete freedom in the use of the limbs being permitted, and in consequence of this it is possible to execute, beyond the ordinary figures, certain difficult figures (some displaying astonishing acrobatic dexterity) such as could not be carried through in the restricted English style. Which style produces the more graceful skating continues matter of debate. Of the many movements (over three hundred) in figure-skating some eight might be said to be fundamental. They are straight-ahead skating, straight-backward skating, the turn to right, the turn to left, skating on the outside edge forward, skating on the inside edge forward, skating on the outside edge backward, skating on the inside edge backward. Except the 'edges' these movements are largely self-explanatory. In the out-

side edge forward the skater, starting, say, on his right foot, describes a wide semicircle to the right, then a similar semicircle on his left foot to the left, and so on alternately. In the inside edge forward the movement is in a sense reversed; the skater, starting again on his right foot, describes a wide semicircle to the left, then a similar semicircle on his left foot to the right, and so on alternately. In the backward edges the forward edges are skated backwards. Waltzing on skates, as all dancing on ice, is really a form of figure-skating.

At St Moritz, Davos Platz, and Grindelwald there are excellent ice rinks. And in countries where there is little natural ice the building of artificial ice-rinks has done much to develop skating.

Hockey on skates is described at HOCKEY; the skates used (it being necessary to unite speed and power of rapid turning in a single skate) are really a compromise between the speed- and the figure-skate; most often they are tubular in design. In sailing on skates a sail arrangement is attached to the body, which forms, so to speak, a mast; speeds of thirty, sometimes forty, miles an hour can be attained.

Wheeled skates were in use on roads in Holland as far back as 1770; but it was only after the introduction of the circular running roller-skate, invented in 1865 by Mr Plimpton of New York, that speed- and figure-skating became common on roller-skates. As to the use of roller-skating as an introduction to ice-skating opinion is divided.

There is a *Bibliography of Skating* (1898) by F. W. Foster. See N. and A. Goodman, *Handbook of Fen Skating* (1882); D. Adams, *Skating* (1889); Heathcote, Tebbutt, and Witham, *Skating* (1892); Monier-Williams, *Figure-skating* (1892); Tebbutt, Read, and Tebbutt, *Skating* (1897, revised as *Skating and Bandy* by Benson, 1921); Benson, *English Figure Skating* (1908); Syers, *Art of Skating* (1912); Cobb, *Figure-skating in the English Style* (1913); Yglesias, *Figure-skating* (1918); Meagher, *Guide to Artistic Skating* (1919); Crawley, *Skating* (1920); Meyer, *Skating* (1922); and a good German book, *Spüren auf dem Eise*, by D. Diamantidi and others (A. Holder, Vienna). On roller-skating there are works by 'Rinker' (1909), Monohan (1909), Burchell (1909), J. F. Davidson (1910), Hewett (1910), J. Williams (1910).

Skean-dhu. See DIRK.

Skeat, WALTER WILLIAM (1835–1912), a learned Early English scholar, was born in London, and educated at King's College School and Christ's College, Cambridge, graduating as fourteenth wrangler in 1858. He became Fellow of his college in 1860, and four years later Mathematical Lecturer there; filled for some time curacies at East Dereham and Godalming; in 1878 was elected the first Elrington and Bosworth professor of Anglo-Saxon at Cambridge, and re-elected to a Christ's College fellowship in 1883. He was the first director of the Dialect Society (established 1873), and by his exhaustive labours on Langland and Chaucer, and innumerable editions of Early English works, he contributed more than any scholar of his time to a sound knowledge of Middle English and English philology generally.

Skegness, a little watering-place of Lincolnshire, 22 miles NE. of Boston. Pop. (1921) 9251.

Skeleton, a general term for the more or less hard parts of animals, whether forming an internal supporting framework—an endoskeleton—or an external exoskeleton, often useful as armour. The term includes so many different kinds of structure and material that it is necessary to take a survey of representative types.

Skeleton of Invertebrates.—Many of the Protozoa have shells of lime (see FORAMINIFERA), or of flint (see RADIOLARIA), or of some organic substance, such as acanthin. These are formed by the living

matter of the units, in the case of the lime and flint shells from materials absorbed from the surrounding water, but in what precise way we do not know. Almost all Sponges (q.v.) are supported by loose or firmly fused spicules of lime or of flint, or have, as in the bath-sponge, an interwoven supporting skeleton of 'horny' fibres. The spicules or fibres are formed by cells in the middle stratum of the sponge. Among Cœlenterates various forms of skeleton, both external and internal, both limy and 'horny,' are represented by the different kinds of Coral (q.v.). With few exceptions these skeletons are produced by cells belonging to the outer layer or ectoderm of the animal. Worms have little that can be called a skeleton, for the tubes, calcareous or otherwise, in which many sedentary worms are sheltered, have no vital connection with the animals which make them. Echinoderms tend to be very calcareous; lime is deposited in the mesodermic tissue of the body in almost any part, though predominantly near the surface. Most Arthropods have well-developed exoskeletons, cuticles formed from the epidermis, consisting in great part of an organic basis of chitin, on which, in Crustaceans and most Myriopods, carbonate of lime is also deposited. As this cuticle is not always restricted to the outside of the animal, but sometimes extends inwards, an apparent endoskeleton arises—e.g. in the lobster, the king-crab, and the scorpion. Most Molluscs have shells in which carbonate of lime occurs along with an organic basis conchiolin, and in cuttle-fish there is a remarkable development of cartilage around the nerve-centres in the head—an analogue of the skull in Vertebrate animals. From this rapid survey it will be seen that the skeletons of Invertebrates are very varied both in structure and in composition; if we except a few doubtful hints of a supporting axis, there are no homologies between the skeletons of Invertebrates and Vertebrates; to the latter, moreover, that form of tissue which we call bone is exclusively restricted.

Skeleton of Vertebrates.—Here we must distinguish first of all between the external exoskeleton and the internal endoskeleton. The scales of fishes, the scales and scutes of reptiles, the scales, claws, and even feathers of birds, the remarkable bony armature of armadillos, the scales of pangolins, the claws of carnivores, the quills of porcupines, and even the hair of ordinary mammals illustrate the variety of structures which may be included within the anatomical conception of an exoskeleton. All these structures are formed in the epidermis, or in the dermis, or in both combined. Tortoise-shell and the scales of reptiles are epidermic; the scutes of crocodiles and the plates covering armadillos are dermic; the scales of Elasmobranch and Ganoid fishes are due to both layers. But it is difficult to carry out any rigidly logical classification. Thus, the dorsal shield of a tortoise is physiologically an exoskeleton, but structurally it is in great part formed from the dorsal vertebrae and from what in other animals form the ribs. The ventral shield of a tortoise is formed from dermal bones, and the so-called abdominal ribs of crocodiles arise as ossifications in the fibrous tissue which lies underneath the skin and above the muscles. The teeth of Elasmobranch fishes are undoubtedly homologous with the dermal denticles or skin-teeth which occur over the skin, and the teeth of mammals are started by enamel germs which sink in from the epidermis of the mouth.

The Vertebral Column.—In a primitive Vertebrate animal like the lancelet the body is supported by a median dorsal axis, and, apart from slight supports for the mouth, the pharynx, and the median fin, this is all the skeleton. The median dorsal axis, which in the lancelet has not even the

firmness of cartilage, is called the notochord, and is one of the constant characteristics of the skeleton of Vertebrates. There is a hint of it in the proboscis of *Balanoglossus* (q.v.) and in *Cephalodiscus* (q.v.); it is more distinct in the tail of young Ascidians (q.v.), and persists throughout life in Appendicularia; in the lancelet, in the hag, and in the young lamprey it is an unsegmented rod with a

Fig. 1.

A, unsegmented notochord (*d*), its sheath (*c*). B, notochord in process of being constricted by its sheath, the parts marked (*v*) corresponding to the centres of two adjacent vertebrae. C, section of a young vertebral column: *d*, the notochord; *c*, its sheath; *b*, the spinal cord protected by neural arches (*a*); beneath are inferior processes (*e*).

yet no vertebral bodies. These begin in the Elasmobranch fishes, in which the notochord is, in part at least, constricted by the encroachment of its sheath, and divided into vertebrae. In the bony Ganoids, such as *Lepidosteus*, the vertebrae are ossified, and so they are more or less thoroughly in all the higher Vertebrates. Yet it is not the notochord which is ossified, but its sheath; the notochord in all higher Vertebrates being merely a provisional structure, an internal scaffolding around which its 'substitute,' the backbone, is built. Each vertebra generally consists of the substantial body or centrum, the neural arches which form a tube for the spinal cord and meet above it in a neural spine, the transverse processes which project laterally and are usually connected with ribs, and the articular processes which bind vertebra to vertebra so that a firm and yet flexible backbone results.

A breastbone or sternum to which the ribs are ventrally united occurs in many Reptiles and in all Birds and Mammals. It arises from a cartilaginous tract uniting the ventral ends of the ribs. In Amphibians also there is a breastbone, but there are no distinct ribs, and it is not certain that we can compare this sternum with that of higher Vertebrates.

The Skull.—In a young Vertebrate animal the cavity in which the brain lies is surrounded by a membranous sheath, but this is gradually replaced, first by a gristly brain-box, and afterwards in most cases by an almost entirely bony skull. Let us first consider the gristly brain-box or chondro-cranium. (*a*) Its foundation is formed from two pairs of cartilaginous plates—posterior parachordals and anterior trabeculae—which lie beside and in front of the notochord. These are extended upwards by a further formation of cartilage; the end of the notochord may also help a little: the result is a cartilaginous brain-box. (*b*) But to the sides of this are added a pair of cartilaginous nasal capsules in front, and a similar pair of auditory capsules behind. (*c*) About the mouth there are some lip or labial cartilages, which may help in forming the skull; but much more important is a series of cartilaginous 'branchial arches' (never more than

simple sheath; in the adult lamprey there are above the notochord rudimentary arches of cartilage forming a trough in which the spinal cord lies; in cartilaginous Ganoid fishes, such as the sturgeon, in the *Chimæra* type, and in the Dipnoi cartilaginous arches appear both above and below the notochord, but there are as

eight pairs), which loop round the pharynx, running between the primitive gill-clefts. Of these arches the two most anterior, which are called the mandibular and the hyoid arches, are of great importance in the development of the skull; the others form supports for the pharynx, and are permanently important only in Fishes and in gilled Amphibians. In Elasmobranch fishes the mandibular and hyoid arches do not form any direct part of the gristly brain box, but in the Teleosteans and thence onwards they, or the bones which replace them, contribute directly to the upbuilding of the skull. To follow the history of the arches, which undergo numerous transformations, is one of the most difficult and interesting tasks of comparative anatomy.

(d) When a bone develops in direct relation to a pre-existent cartilage which it replaces, it is often called a primary or 'cartilage bone'; and there are many regions of the cartilaginous brain-box which in the course of development are thus replaced by bones. But there are other bones which develop independently of pre-existent cartilage. They invest the cartilaginous brain-box on its roof, on its floor, and on its sides. They are comparable to the dermal ossifications or scutes which occur in Ganoid fishes and many other animals, and they are often called secondary or 'membrane' bones. In structure they are of course indistinguishable from 'cartilage bones'; in origin too they are in one way the same, for all bones arise from a (periosteal) membrane of bone-making cells; but 'cartilage bones' are at one time represented by cartilages, whereas 'membrane bones' never are.

To sum up, the skull is formed (a) from the parachordals and trabeculae at the end of the notochord, (b) from the adjacent sense-capsules of the nose

ossification and investing bones begin with the Ganoid fishes, and are numerous in Teleosteans and in all higher animals. In the development of the individual there is a parallel progress.

Theory of the Skull.—About the beginning of the 19th century Oken and Goethe independently suggested what is known as the vertebral theory of the skull—that the skull is comparable to a number of vertebrae. To this Owen lent his authority, but it has been disproved by the subsequent discoveries of comparative anatomy and embryology (see SKULL).

The Appendicular Skeleton.—Somewhat apart from the axial skeleton are the limbs and the girdles to which these are attached. No secure conclusion has yet been reached as to origin of the limbs of Vertebrates. In the simplest forms—the Tunicates, the lancelet, the Cyclostomata—there are none, and there is a very marked difference between the fin like limbs of fishes and the fingered and toed limbs which occur in almost all higher backboneed animals. According to Gegenbaur, the pectoral and pelvic girdles are structures comparable to the branchial arches, and he supposed that the primitive limbs were made up of modified fin-rays comparable to those which support the unpaired fins of fishes. According to Dohrn the limbs are residues of a longitudinal series of segmentally arranged outgrowths, perhaps comparable to the appendages of a typical Annelid worm (see FISHES, VERTEBRATA). According to others, the limbs are concentrations of two lateral fin folds.

The pectoral or shoulder girdle consists of a dorsal shoulder-blade or scapula, a ventral coracoid, with the articulation for the arm between them, and of a forward growing collar-bone or clavicle. The pelvic or hip-girdle consists on each side of a dorsal ilium, a ventral ischium, with the articulation of the leg between them, and of a third pubic position. The fore-limb—from Amphibians onwards—consists of a humerus articulating with the girdle, a lower arm composed of radius and ulna lying side by side, a wrist or carpus of several elements, a hand with metacarpal bones in the palm and with fingers composed of several joints or phalanges. The hind-limb—from Amphibians onwards—consists of a femur articulating with the girdle, a lower leg composed of tibia and fibula lying side by side, an ankle region or tarsus of several elements, a foot with metatarsal bones in the sole and with toes composed of several joints or phalanges. Distinct from all the other bones are a few little 'sesamoids' which are occasionally developed within tendons and

d and g, parts of first or mandibular arch; f, part of second or hyoid arch; behind these the arches (h) separating gill-clefts; a, c, the nasal and auditory capsules, (b) the eye

and the ear, (c) from the more or less intimately associated mandibular and hyoid arches, (d) from the ossification of the gristly brain-box due to (a), (b), and (c), but also from 'membrane bones' or investing bones which arise independently of pre-existent cartilages. There is no skull in Tunicates or in the lancelet; it is cartilaginous in Cyclostomata and Elasmobranchs; centres of

near joints, notably, for instance, the knee-pan or patella.

The Skeleton of Man.—As the bones of all the chief parts of the human body are described in separate articles, we need not do more than unify these by reference to a diagram of the entire skeleton (fig 5). Altogether there are more than 200 bones, but some which are originally distinct become fused with their neighbours.

In the vertebral column there are originally thirty-three vertebrae, but in adult life the normal number is twenty-six, for, while the first twenty-four remain distinct, five (the twenty-fifth to the twenty-ninth

inclusive) unite to form the sacrum supporting the hip girdle, and the four hindmost fuse more or less completely in a terminal tail-piece or coccyx. Seven cervicals support the neck; twelve dorsals form the

small beak-like bone—the coracoid—which is separate in Birds and Reptiles, but reduced to a mere process of the scapula in all Mammals except the Monotremes. Stretching from the breastbone to shoulder blade is the curved collar bone or clavicle.

The skeleton of the leg also includes thirty bones—in the thigh the femur, which articulates with the hip girdle; in the lower leg the shin bone or tibia and the splint bone or fibula, which articulate with the femur at the knee-joint, where there lies a little 'sesamoid' bone—the patella; in the ankle region seven bones, then five metatarsal bones forming the sole of the foot, and five toes with the same number of phalanges as in the fingers. The pelvic girdle consists in early life of three paired bones—large dorsal ilium, a posterior ischium, an anterior pubis on each side—but these unite about the twenty-fifth year into single haunch-bone, with the socket of which the thigh articulates. See ARM, HAND, SHOULDER-JOINT, FOOT, LEG, PELVIS, RIBS, SKULL, and SPINAL COLUMN; for literature, see the works referred to in the article ANATOMY. Skeletons other than human will be seen under the headings of ANTHROPOID APES, BAT, BIRD, ELK, FISHES, HESPERORNIS, ICHTHYOSAURUS, IGUANODON, MEGATHERIUM, PLESIOSAURUS, &c; and skulls at BABIROUSSA, CARNIVORA, DOG, RODENTIA, &c.

Skelligs, three rocky islands on the south west coast of Ireland, lying 10 miles SW. of Valentia island. On one of the rocks stands a lighthouse, the light of which is 175 feet above high water, and visible 18 miles at sea. On Great Skellig (710 feet high) are the ruins of a monastery.

Skelmersdale, a town of Lancashire, $4\frac{1}{2}$ miles from Ormskirk; pop. 6700.

Skelton, JOHN, an early satirical poet, is supposed to have been born about 1460, most probably in Norfolk, although generally said to have been sprung from a Cumberland family. He studied at Cambridge, perhaps also at Oxford, and received from each the academical honour of laureate. He was appointed tutor to the young prince Henry, and early acquired such reputation for learning that Erasmus styles him 'the one light and ornament of British letters.' He took holy orders in 1498, and became rector of Diss in Norfolk, but seems later to have been suspended for keeping a concubine; although Fuller tells us how, on his death-bed he protested 'that in his conscience he kept her in the notion of a wife, though such his cowardliness that he would rather confess adultery (then accounted but a *venial*) than own marriage, esteemed a capital crime in that age.' Wood tells us that he 'was esteemed more fit for the stage than the pew or pulpit,' and Churchyard says 'his talke was as he wraet.' Already he had produced some translations, and elegies upon Edward IV. and that Earl of Northumberland murdered by a Yorkshire mob in 1489; but now he stuck into an original vein of satirical vernacular poetry, in rattling verses of six, five, and even four syllables, with quick-recurring rhymes, overflowing with grotesque words and images and unrestrained jocularity, and lightened up by bright gleams of fancy. His bent leaned strongly towards satire, and in this kind his chief productions were *The Bouge of Courte*, *Colyn Cloute*, and *Why come ye*

Fig. 5.—Human Skeleton.

greater part of the back and bear ribs; five lumbar occur in the loins; these are followed by the sacrum and the coccyx (see SPINAL COLUMN).

The ribs, or elastic arches of bone which bound the chest, are normally twelve on each side. Most of them articulate dorsally with the bodies of two adjacent vertebrae and with the transverse processes of the posterior one; ventrally the first seven pairs are connected with the median breastbone by means of intervening cartilages, while the posterior five pairs are more or less free (see RIBS).

The skull consists in early adult life of twenty-two separate bones, but originally there were more, and as life continues the number may be further reduced by fusion. For the various bones, see SKULL.

The skeleton of the arm includes thirty bones—in the upper arm the humerus, which articulates with the shoulder-girdle; in the forearm the radius and ulna, which articulate with the humerus at the elbow; the wrist of eight carpal bones; the five metacarpals of the palm; the five digits, of which the four fingers have each three joints or phalanges, while the thumb has two. The important bone of the pectoral girdle is the shoulder blade or scapula. To this, at the shoulder joint, there is fused a

nat to Courte. Of these the first is an allegorical poem showing stinking power of characterisation; the second, a vigorous and unsparing attack on the corruptions of the church, of which he himself says, 'though my ryme be ragged, tattered and jagged, rudely rain-beaten, rust and moth-eaten, if ye take well therewith, it hath in it some pyth'; the last is a sustained invective against Cardinal Wolsey. He attacks with the most plain-spoken boldness his arrogance, avarice, and incontinence, and does not spare even his 'gresy genealogy' and the 'bocher's stall.' Wolsey felt the sting, and tried to arrest his libeller, but Skelton fled to the sanctuary in Westminster, where Abbot Islip sheltered him till his death, June 21, 1529. Of his other poems the chief are *Phyllipp Sparowe*, a young girl's lament for a pet bird killed in a convent of black nuns at Carowe near Norwich, an amusing but rather profane *jeu d'esprit*, which Coleridge called 'an exquisite and original poem'; *The Tunnyng of Elynour Rummynge*, a vigorous burlesque picture of low life, its heroine an ale-wife at Leatherhead in Surrey; the *Garlande of Laurell*, a long but less successful poem; and *Magnifycence*, the only one of his Interludes that has survived. Skelton's reputation for wit, if not ribaldry, was so great that a wretched book of 'merye tales' was popularly linked with his name: as undeserved is Pope's phrase—'beastly Skelton'—written on occasion of a reprint in 1736 of the first collected edition (1668). The only good edition is that by the Rev. A. Dyce (2 vols. 1843). A selection edited by Richard Hughes (1924) is based on Dyce.

Skene, WILLIAM FORBES, an erudite Scottish historian, was born at Inverie on Loch Ness, June 7, 1809, the second son of Scott's friend, James Skene (1775-1864). He had his education at Edinburgh High School, in Germany, and at the universities of St Andrews and Edinburgh, afterwards, in 1834, becoming a Writer to the Signet in Edinburgh. In 1879 he received the D.C.L. degree from Oxford, and in 1881 he succeeded Hill Burton as Historiographer for Scotland. He died on the 29th August 1892. Among his most important works are *The Highlanders of Scotland* (2 vols. 1837), *The Dean of Lismore's Book: a Selection of Ancient Gaelic Poetry* (1861); *Chronicles of the Picts and Scots* (1867); *Foidun's Cronica Gentis Scottorum* (2 vols. 1871); *The Four Ancient Books of Wales* (2 vols. 1868); *Celtic Scotland, a History of Ancient Alban* (3 vols. 1876-80); and *Memorials of the Family of Skene of Skene* (New Spalding Club, 1887).

Skepticism. See SCEPTICISM.

Skerries, a name applied to several groups of isolated rocky islets round the coasts of Great Britain, more especially a group about 2 miles off the north-west coast of Anglesey, having a lighthouse 117 feet high. See also PENTLAND FIRTH.

Skerries, an Irish seaport, 18 miles N. by E. of Dublin. Pop. 1800.

Skerryvore, the chief rock of a reef which lies 10 miles SW. of Tyree and 24 W. of Iona. This reef, which stretches 8 miles west-south-westward, is composed of compact gneiss, worn smooth by the constant action of the waves, and was long a terror to mariners, having caused the loss of one ship annually for forty years previous to 1844. The Northern Lighthouse Commission had long intended the erection of a lighthouse on Skerryvore, the only point of this dangerous reef which could afford the needful foundation; but the difficulty of landing on the rock, from the immense force (3 tons to the superficial foot) with which the Atlantic waves beat upon it, caused the delay of the scheme till 1838. The design and superintend-

ence of the building were entrusted to Alan Stevenson, who followed generally the mode adopted by his father, Robert Stevenson, in the construction of the Bell Rock Lighthouse, and completed his work in 1844. The lighthouse is 138½ feet high; at the base 42, and at the top 16 feet in diameter. The revolving light can be seen 18½ nautical miles away. The cost was £86,977. See the book by A. Stevenson (1848).

Ski. See SNOW-SHOES.

Skibbereen, a market-town of the county of Cork, Ireland, 54 miles SW. of Cork, at the terminus of a branch-line, with a little trade in agricultural produce. It suffered terribly during the famine of 1846-47. Pop. 3000.

Skiddaw, a mountain (3054 ft.) of Cumberland, flanking the east side of Bassenthwaite Water, and 5½ miles NNW. of Deventwater and Keswick.

Skimmer, or SCISSORS-BILL (*Rhynchops*), a genus of long-winged sea-birds belonging to the Gull family (*Laridae*). Their most distinctive feature is the long, thin bill with the lower half longer than the upper. There are only three known species, occurring respectively in Asia, Africa, and America. Darwin describes the American skimmers, or, as they are also called, Shearwaters (*R. niger*), as skimming along the surface of the water, generally in small flocks, plunging up small fish with their projecting lower mandible, and securing them with the upper half of their scissors-like bills. See GULL.

Skin. The skin forms a complete covering for the outer surface of the body, and consists of two distinct layers, of which the outer is termed the *epidermis*, *cuticle*, or *scarf-skin*, and the inner the *corium* or *cutis vera*. Moreover, the skin contains certain structures termed 'tactile corpuscles,' by means of which the properties of bodies are revealed to the sense of touch; and associated with the skin there are such accessory organs as hair, nails, sebaceous glands, and sweat-glands.

The *epidermis* is non-vascular, and forms a protective covering for the *cutis vera*. It varies in thickness from $\frac{1}{16}$ th to $\frac{1}{4}$ th of an inch, being

Fig. 1.—Section of Epidermis from the Human Hand, highly magnified (Ranvier):

A, horny layer, consisting of a, superficial horny scales; b, swollen out horny cells; c, stratum lucidum; B, rete mucosum, consisting of d, prickly cells; e, elongated cells near corium; f, a nerve-fibre.

thickest in the palms of the hands and soles of the feet. In structure it consists of cells, closely adherent to each other by their margins, and arranged in many irregular layers. The individual cells vary in shape, being perpendicular in the deepest layer, and passing by various transitions into a surface stratum of hardened, flattened cells, which are constantly being thrown off by desquamation; fig. 1 shows the various transitions. In many of the cells, even of white races, pigment granules are found, and these account for the tawny colour of the skin. A section of the epidermis of a Negro's leg, showing the cells of the horny and mucous layers, will be found

at Epidermis (q.v.). If a large portion of the epidermis be removed, the process of repair is slow, and proceeds from the edges of the wound, but recovery is quicker if any of the deeper cells of the layer remain. Skin-grafting aims at transplanting small portions of healthy epidermis—including its deeper layers—to denuded surfaces, and when the grafts take root the raw surface is much more speedily covered because the healing process spreads from each graft (see RHINOPLASTIC OPERATIONS). Nails (q.v.) and Hair (q.v.) are growths of the epidermis.

The *cutis vera*, *corium*, or *true skin* is a vascular and sensitive structure, everywhere covered by the epidermis. It rests on a layer which in most places contains fat—the *panniculus adiposus*—and to this layer the corium is sometimes loosely, sometimes firmly, attached. In structure the true skin consists of an interlacing network of white fibrous tissue with a mixture of elastic fibres. On its deep aspect the meshes are more open, and contain lumps of fat. In this way the corium gradually blends with the subcutaneous layer, and so its thickness is not definite, but is generally regarded as varying from $\frac{1}{16}$ th to $\frac{1}{8}$ th of an inch. Wherever hairs occur bundles of muscular fibres are found. The outer surface of the corium is characterised by furrows, which also affect the epidermis. The largest furrows are found opposite the flexures of joints. Finer furrows may be seen on the backs of the hands; while on the skin of the palms and soles ridges with intervening furrows form patterns which are characteristic of each individual. These patterns are permanent, and do not materially change from infancy to adult life (Galton). The latter furrows are due to the fact that the outer surface of the corium is beset with small elevations termed *papillæ* (fig. 2). These are most fully

Fig 2.—Compound Papillæ of Surface of Hand :
a, base of a papilla; b, b, their separate processes. Magnified 60 diameters.

developed where touch is finest, and they fit into corresponding depressions on the under surface of the epidermis. The deeper layers of the corium are plentifully supplied with blood-vessels, which form a fine network of capillaries from which loops pass into most of the papillæ. Lymph vessels are also numerous, and as these communicate freely with the inter-cellular spaces, wounds which penetrate the cuticle may readily admit septic substances into the circulation. Fine nerves are also supplied to the corium for distribution to the 'touch corpuscles' found in certain papillæ. As a rule papillæ with touch corpuscles have no capillary loop, and thus we distinguish 'vascular' and 'tactile' papillæ. The hair-follicles also receive nerves, and fine varicose nerve-fibrils pass into the deeper layers of the epidermis. *Sebaceous glands*, found wherever hairs are present, pour their secretion into hair-follicles at a short distance from the mouth, unless the hair be small, when the gland may open on the surface of the skin, and the hair project through its duct. Being outgrowths of the hair-follicles they are accessory structures to the epidermis, although the body of the gland is lodged in the corium. They are specially abundant in the

scalp and face—some of the largest being found on the side of the nose. Their secretion consists of the fatty degenerated and disintegrated cells which line their interior (see ACNE).

Sweat-glands are found at various depths beneath the corium. Each gland is a coiled-up tube, of which the *duct* is that part leading in a corkscrew manner through the corium and epidermis to the surface. These glands are also outgrowths of the epidermis, and they are lined by epithelial cells. They are most numerous where there is no hair, but they occur everywhere in connection with the skin. Krause states that 2800 open on a square inch

Fig. 3.—Magnified view of a Sweat-gland, with its duct (Wagner):

a, the gland surrounded by fat cells; b, its duct, passing through corium and epidermis.

of skin from the palm; half as many on a similar area on the back of the hand; fewer on the surface of the forehead; 1100 on breast and forearm; while from 400 to 600 are found on the square inch of the lower limbs and back of the trunk. The sweat is naturally *alkaline*, although it may be found acid owing to the presence of fatty acids derived from the decomposition of sebum. In prolonged sweating the secretion becomes neutral and again alkaline. It is colourless, of a saltish taste, and its odour, which is due to volatile fatty acids, varies with different parts of the body. Coloured sweat is among the phenomena of nervous affections, and instances of blue and bloody sweats are on record. In jaundice the sweat may contain bile-pigment.

Ceruminous glands are found in the auditory passage, and have such a close resemblance to sweat-glands that the former may be regarded as modifications of the latter. They yield an adhesive bitter secretion—the wax—which

protects the drum of the ear from insects, dust, &c.

The most important function of the skin, Touch (q.v.), is separately treated. Regarded as a protective covering, the skin possesses the combined advantages of toughness, resistance, flexibility, and elasticity; the connective framework being the part which mainly confers these properties, although the epidermis co-operates with it. The subcutaneous layer of fat, and the modifications of epidermis in various forms, as hairs, wool, feathers, scales, &c., serve for the preservation of warmth, and occasionally (when they occur as claws, talons, &c.) as means of offence or defence. The skin is the seat of a twofold excretion—viz. of that formed by the sudoriparous glands and that formed by the sebaceous glands. The fluid secreted by the sudoriparous glands is usually formed so gradually that the watery portions of it escape by evaporation as soon as it reaches the surface; but in certain conditions, as during strong exercise, or when the external heat is excessive, or in certain diseases, or when the evaporation is prevented by the application of a texture impermeable to air, as, for example, oiled silk, or the material known as mackintosh, or india-rubber cloth, the secretion, instead of evaporating, collects on the skin in the form of drops of fluid. When it is stated that the sweat contains urea, lactates, extractive matters, &c., and that the amount of watery vapour exhaled from the skin is, on an average, 2½ lb. daily, the importance of the sudoriparous glands as organs of excretion will be at once manifest. Moreover, there is reason to believe, from the experiments of Scharling, Gerlach,

and others, that the importance of the skin as a *respiratory* organ is far from inconsiderable, very appreciable quantities of carbonic acid being exhaled hourly by the external surface of the body. In the amphibia, in which the skin is thin and moist, the cutaneous respiration is extremely active, and that the respiratory function of the skin in the higher animals is also considerable is proved not only by measuring the excreted carbonic acid, but by the fact that if the skin is covered by an impermeable varnish, or if the body is enclosed, all but the head, in a caoutchouc dress, animals soon die, as if asphyxiated, their heart and lungs being gorged with blood, and their temperature before death gradually falling many degrees.

The skin is, moreover, an organ of absorption: mercurial preparations, when rubbed into the skin, have the same action as when given internally. Thus potassio-tartrate of antimony, rubbed into the skin in the form of ointment or solution, may excite vomiting, or an eruption extending over the whole body. The effect of rubbing is probably to force the particles of the matter into the orifices of the glands, where they are more easily absorbed than they would be through the epidermis. It has been proved by the experiments of Madden, Berthold, and others, that the skin has the power of absorbing water, although to a less extent than occurs in thin-skinned animals, such as frogs and lizards. This fact has a practical application. In severe cases of dysphagia—difficult swallowing—when not even fluids can be taken into the stomach, immersion in a bath of warm water, or of milk and water, may assuage the thirst. Sailors, also, when destitute of fresh water, find their urgent thirst allayed by soaking their clothes in salt water.

The more important *diseases* of the skin are noticed in special articles. See also ALBINOS, BATHS, NERVOUS SYSTEM, TASTE, TOUCH. The colour of the skin as a race-feature is dealt with at ETHNOLOGY. Peculiarities in the skins of various animals are treated in the articles on those animals (HIPPOPOTAMUS, RHINOCEROS, &c.). For skins as articles of commerce, see FURS, LEATHER. For the stuffing of animals, see TAXIDERMY.

SKIN-CASTING is a popular term for processes which vary not a little in degree and even in nature. In most cases the outer layer of the epidermis tends to die away, and is separated off either very gradually and in small pieces at a time, or in large shreds, or in a continuous slough (see SNAKES). The moulting of feathers and the casting of hair are analogous. In the moulting or 'ecdysis' of Crustaceans and other Arthropods, what is cast is the cuticle—a product of the underlying epidermis. See CRAB, CRAYFISH, CRUSTACEA.

Skink (*Scincus*), a genus of lizards in North Africa, Arabia, Persia, and Sindh. The species burrow and run about swiftly in dry sandy places.

Skink (*Scincus officinalis*).

They live on insects, and are eaten by snakes and larger lizards. The Common Skink (*S. officinalis*) of the Sahara and Egypt is about 8 inches long. It has a wedge-shaped snout, two pairs of rather

strong limbs, small eyes, and smooth scales with bony scutes beneath. It is yellowish or brownish above (salmon-coloured in youth), with each scale spotted; the under-parts are whitish. Its skin is in great repute for imaginary medicinal virtues; indeed, skink-powder is a panacea. Other skinks or Scincidae are the African Mabui (M. vittata, the 'poisson de sable,' is semi-aquatic); the genus Chalcides or Seps (some of which have vestigial limbs, in adaptation to burrowing); the common Australian *Trachysaurus rugosus*; the large *Cyclodius gigas* of New Guinea and the Moluccas, nearly 2 feet long. See LIZARDS.

Skinner, JOHN, the author of 'Tullochgorum,' was born in the parish of Birse, Aberdeenshire, 3d October 1721, the son of the schoolmaster there. He graduated at seventeen at Aberdeen, taught in the parish schools at Kenmay and Monymusk (where he left the Presbyterian for the Episcopal Church), and in 1740 went as private tutor to Shetland, where he married the daughter of the Episcopal clergyman. In 1742 he was ordained a deacon, and placed at Longside, where he ministered for sixty-four years. In 1746 his house was pillaged and his chapel burned by the Hanoverian soldiery, although Skinner was no Jacobite, and was one of the few who, so far as he could, complied with the terms of the Toleration Act—for which, however, he had to receive the absolution of his bishop, the church at large regarding compliance as sin. The Act of 1748 he and his people evaded for the most part, and in 1753 he was imprisoned for six months. At some period before 1789 he became dean of the diocese; and he died at Aberdeen, in his son's house, 16th June 1807.

Skinner is remembered only by a few songs. He published *An Ecclesiastical History of Scotland* (2 vols. 1788), and several controversial writings; and other works appeared posthumously, including those wrought out after the theory of John Hutchinson (q.v.). His *Poems* were collected in 1809 (3d ed. 1859), the best being 'The Ewie wi' the Crookit Horn' and 'Tullochgorum'—praised by Burns, in a friendly letter to Skinner (1787), as 'the best Scotch song Scotland ever saw.' See the *Life* by the Rev. Dr Walker (2d ed. 1883).

His son, **JOHN SKINNER**, Primus of Scotland, was born at Longside, 17th May 1744, in 1753 shared his father's imprisonment, and graduated at Aberdeen at the age of sixteen. In 1763, when only nineteen—for the same reason as in the case of Dr Chalmers, because he was 'a lad of pregnant parts'—he was ordained and placed in charge of Ellon, with a stipend of £25 a year, eked out by farming. Eleven years later he was called to Aberdeen, where by 1776 his congregation had so increased as to compel his removal to a larger house at Longacre, where the upper floor as usual was fitted up as a 'meeting-house'—the large 'upper room' in which Dr Seabury was consecrated in 1784. By this time Skinner had been made coadjutor-bishop (1782), and in 1787 he became bishop of the diocese, and in 1788 primus. The death of Prince Charles Edward, which occurred in this last year, was the solution of the church's Jacobite difficulty; and the leading part in obtaining the Relief Act of 1792 fell to the primus. Skinner proved a wise and successful administrator, and his great influence was exerted invariably for the real good of the church. He died on 13th July 1816, and was succeeded as bishop by his son. See the *Life* by Dr Walker (1887).

Skipton, a market-town in the West Riding of Yorkshire, is finely situated in the broad and fertile valley of the Aire, 26 miles NW. of Leeds. The capital of Craven, it is a gray-looking place, with manufactures of cotton and woollen goods, and is an important station on the London Midland and Scottish line. The castle, once the chief seat of

the Cliffords (q.v.), is of two periods, the reigns of Edward II. and Henry VIII., and is partly a ruin, partly inhabited. The church has some interesting monuments; and there are also a public hall (1861), a grammar-school (1548; rebuilt in 1876-77), a girls' high school, and a saline spring. Bolton Abbey (q.v.) is 6 miles distant. Pop. (1851) 4962; (1921) 12,013.

Skirret (*Sium Sisarum*), a perennial plant of the family Umbelliferae, a native of China and Japan, but long cultivated in gardens in Europe for its roots, which are tuberous and clustered, sometimes 6 inches long, and as thick as the finger. They are sweet, succulent, and nutritious, with a somewhat aromatic flavour, and when boiled are a very agreeable article of food. A kind of spirituous liquor is sometimes made from them. Good sugar can also be extracted. Skirret was at one time more cultivated in Britain than it is at present, although there seems to be no good reason for its having fallen into disrepute. Worledge called it the 'sweetest, whitest, and most pleasant of roots.' It is propagated either by seed or by very small offsets from the roots. It has a stem of 2 to 3 feet high; the lower leaves pinnate, with oblong serrated leaflets, and a heart-shaped terminal leaf, the upper ones ternate with lanceolate leaflets.

Skittles, a game usually played in a covered shed, called a skittle-alley, about 60 feet in length. The skittles are made of hard wood of the shape shown at A in the fig., and they are placed upon

the floor of the shed in the order shown at *a*. The player, standing at *b*, trundles a wooden missile, shaped like a small, flat cheese, from 7 to 14 lb. in weight, and tries to knock down the whole of the skittles in as few throws as possible. The game is very similar to the American bowls, which is played with ten pins arranged in the form of a triangle; and the missile, a round wooden ball, is rolled along a carefully constructed wooden floor. The game of skittles (*Kegel*) with round balls is zealously played in most parts of Germany, but with great local variations. Thus in Silesia there are sometimes fifteen or seventeen pins, though the usual number is nine; and in some places the round balls have holes in them for the fingers of the player—so that they are thrown rather than trundled. Sometimes the pins have different forms and values, one being called the king; and there are many ways of arranging them. The game seems to be of ancient Germanic origin, and to have come from Germany to the Netherlands, England, and France. It is described by Hugo von Trimberg, rector of a monastery at Bamberg in the second half of the 13th century (when there were only three pins). The old English game was called *Kails* (Sir Philip Sidney has *Keels*; in Scotland *Kyles*—all apparently derived from the German *Kegel*), and was played, not with a ball or disc, but with a short club—according to Strutt, 'with a sheep's leg-bone.' There is a learned monograph on the game by Rothe (Halle, 1879). See also **BOWLS**.

Skobelev, MICHAEL DMITRIEVITCH, Russian soldier, born in 1841, entered the Russian guards when twenty, fought through the war of the Polish rising (1863), and in 1866 was called to join the general staff. During the years 1871-75 he was on active duty in Asia, preparing for and then taking

part in the conquest of Khiva and conquering Khokand. In the Russo-Turkish war of 1877-78 he bore a conspicuous part: in the stormings of Plevna he commanded the left wing and entered that position at the head of his army corps; and he took prisoners the so-called Shipka army of the Turks and captured Adrianople. In 1880 he was back again in Asia; and it was he who commanded at the storming of the Turkoman stronghold Geok Tepe (24th January 1881). Skobelev was one of the recognised leaders of the aggressive and militant wing of the Pan Slavist agitators; but he died suddenly on 7th July 1882, at Moscow, before he could put his ambitious schemes into execution.

See *Personal Reminiscences of General Skobeloff*, by Nemirovitch-Danchenko (Eng. trans. 1884), and the *Life* in German by Ossipovitch (Hanover, 1887).

Skoplje (Turkish, *Üskub*; Greek, *Slopeia*), an old capital of Serbia, recovered from Turkey in 1912, stands on the Vardar, 130 miles by rail N.W. of Salonika. It has an Orthodox archbishop and a Catholic bishop. Pop. 41,000.

Skoptsy. See **RUSSIA** (*Raskolniks*).

Skowhegan, a town of Maine, capital of Somerset county, on the Kennebec, 37 miles by rail N.N.E. of Augusta. The Kennebec falls provide power for electric plant, and there are manufactures of woollens, timber products, paper, rugs, and flour. There is some cattle-raising, while agriculture and dairy-farming are important. Pop. 6000.

Skriabin, ALEXANDER (1872-1915), Russian composer, studied under Taneieff and Safonoff at the Moscow Conservatoire, and lived variously at Moscow, Beatenberg in Switzerland, and Brussels, besides making many concert tours as pianist. His compositions (mostly for the piano, and containing nothing for the voice) can be grouped roughly into three periods—the first, up to Op. 25 (1897), includes the First Symphony, the Sonatas Nos. 1, 2, and 3, and numerous books of Preludes; the second, up to Op. 52 (1908), the Second and Third Symphonies, the Sonata No. 4, a *Fantasia*, the *Poème Satanique*, and further Preludes; the third, up to Op. 74 (1915), the Fourth and Fifth Symphonies (*Poème de l'Extase* and *Prometheus*), the Sonatas Nos. 5 to 10, a *Poem-Nocturne*, *Vers la Flamme*, &c. In his second period, Skriabin throws off the influences of Chopin and Liszt that characterise the earlier works, and his style becomes rapid and luminous, but it is not until the third period that he definitely associates music with theosophy (experimenting, too, in combinations of music with colour, light, and perfume), and finally abandons the use of key-signatures, building up whole pieces round a single chord, which is regarded as the tonic for the time being.

See the *Studies* by Eaglefield Hull (1916; rev. 1922) and Swan (1923).

Skua, or **SKUA GULL**. See **GULL**.

Skull. The skull is divided into two parts, the cranium and the face. In human anatomy it is customary to describe the former as consisting of eight and the latter of fourteen bones; the eight cranial bones, which constitute the brain-case, being the *occipital*, two *parietal*, *frontal*, two *temporal*, *sphenoid*, and *ethmoid*; while the fourteen facial bones, which surround the cavities of the mouth and nose and complete the orbits or cavities for the eyes, are the two nasal, two superior maxillary, two lachrymal, two malar, two palate, two inferior turbinated, vomer, and inferior maxillary. The bones of the ear, the teeth, and the Wormian bones are not included in this enumeration. The lower jaw articulates with the temporal bones by means of a diarthrodial joint (see **JOINTS**), but all the others are joined by *sutures*. On the base of the

cranium the occipital and sphenoid bones articulate by means of a plate of cartilage (synchondrosis) in young subjects; in adults this becomes bony union. Sutures are named from the bones between which they are found, but to those around the parietal bones special names are given—e.g. interparietal or *sagittal*; occipito-parietal or *lambdoid*; fronto-parietal or *coronal*; parieto-temporal or *squamous*. During adult life many of the sutures close by bony union and disappear, but both the age at which this occurs and the order of its occurrence are subject to variation. Wormian bones are irregular ossifications found in relation to the sutures of cranial bones, but seldom seen in relation to the bones of the face. They are most frequent in relation to the lambdoid suture, and seldom one inch in diameter. The closure of a suture stops the growth of the skull along that line, and in order to compensate for this defect an increase of growth may occur at right angles to the closed suture and thus irregularities of form may result: for example, closure of the sagittal suture stops transverse growth, but the skull continues to grow in the longitudinal and vertical directions, with the result that a boat-shaped cranium is produced—*scaphocephaly*. Irregular forms may be produced artificially by pressure applied early in life. This is best seen among certain American tribes who compress their children's heads by means of boards and bandages. The bones of the skull are pierced by holes (*foramina*), and similar holes are found in relation to the adjacent margins of bones. Most of these foramina are situated

Fig. 1.—Side View of Human Skull:

a, frontal bone; b, parietal bone; c, occipital bone; d, temporal bone (squamous portion); e, sphenoid bone; f, malar bone; g, nasal bone; h, superior maxillary or upper jaw bone; i, inferior maxillary or lower jaw bone. BD, height of cranium; GO, length of cranium; BN, basinasal length; BA, basialveolar length. (These measurements are supposed to be made in a straight line from point to point.)

in the base or floor of the skull, and are for the ingress of arteries and the exit of veins, lymph vessels, and cranial nerves. The largest of these foramina—the foramen magnum—is found in the occipital bone. It is situated immediately above the ring of the atlas vertebra, and through it the continuity between the brain and spinal cord is established, and further, it transmits the vertebral arteries which enter to supply blood to the brain. Compared with the skulls of animals, the form of the human skull is modified (1) by the proportionately large size of the brain and the consequent expansion of the bones which surround it; (2) by the smaller size of the face, especially of the jaws, so that the face of man, instead of projecting in

front of, is *under* the forepart of the cranium; (3) by the *erect attitude*, which places the base of the skull at a considerable angle with the vertebral column, and, in consequence of a development backwards from its point of articulation with the vertebrae, the skull is nearly balanced on the summit of the vertebral column. Hence the orbits look forwards and the nostrils look downwards. The development of the skull is a subject of great interest, not only in itself, but as throwing light on many points which the study of the adult skull would fail to explain. At a very early period of fetal existence the cerebrum is enclosed in a membranous capsule external to the dura mater, and in close contact with it. This is the first rudiment of the skull, the cerebral portion of which is consequently formed before there is any indication of a facial part. Soon, however, four or five processes which jut from it on either side of the mesial line, grow downwards, incline towards each other, and unite to form a series of inverted arches, from which the face is ultimately developed. Imperfect development or ossification of these rudimentary parts of the face give rise to 'harelip' and 'cleft-palate,' or in very extreme cases to the monstrosity termed 'Cyclopean,' in which, from absence of the frontal processes, the two orbits form a single cavity, and the eyes are more or less blended in the mesial line.

The cartilage, formed at the base of the membranous capsule, is speedily followed by the deposition of ossific matter at various points of the capsule, which soon becomes converted into flakes of bone; while the intervening portions, which remain membranous, permit the skull to expand as its contents enlarge. Then follows the appearance of osseous nuclei in the cartilage at the base, corresponding to the future occipital and sphenoid bones. Lastly, the various bones, some originating in membrane, and some in cartilage (see OSSIFICATION), approach one another by gradual enlargement, and become united in various ways, so as to form a continuous, and ultimately an unyielding bony case, which is admirably adapted for the defence of the brain, for sheltering the organs of special sense, and for being attached to the ligaments and muscles by which the skull is supported

Fig. 2.—Human Skull at Birth, from above:

1, anterior fontanelle; 2, posterior fontanelle; 3, sagittal suture; 4, 4, coronal suture; 5, lambdoid suture; 6, 6, parietal bones; 7, 7, two halves of the frontal bone, still ununited; 8, occipital bone.

and moved on the spine. At the period of birth most of the principal bones have grown into apposition with their neighbours, forming the sutures; but one large vacuity remains at the meeting-point of the parietal and frontal bones, which is termed the anterior fontanelle (so called from the pulsations of the brain, which may be here seen resembling the rising of water at a spring or fountain. There are two fontanelles in the mesial line (as shown in fig. 2), and two lateral fontanelles on either side (as shown in fig. 3), which do not close till the second year after birth, and sometimes remains open much longer. The deficiency

of the osseous brain-case at this position not only facilitates delivery, but also acts to some extent like a safety-valve during the first months of infantile life, at which time the brain bears an unusually large proportion to the rest of the body,

Fig. 3.—Human Skull at Birth (side view):
1, 2, lateral fontanelles

and is liable to sudden variations of size from temporary congestion, and other causes. The sutures remain distinct long after the closure of the fontanelles, and serve a purpose both in permitting an increase of the size of the cranium by the growth of the bones at their edges, and in diminishing and dispersing vibrations from blows, and thus contributing to the security of the brain.

The number of centres of ossification in the skull is tolerably constant; each bone having a certain number. After the sutures have been formed, and the skull has acquired a certain thickness, a process of resorption commences in the interior of the bones, and reduces the originally dense structure to a more or less cellular or cancellated state. The interior thus altered is called the *Diploë*, and by this change the weight of the skull is much diminished while its strength is scarcely affected. The *diploë* usually begins to be apparent about the tenth year, and is most developed in those skulls which are thickest. A continuation of the same process of resorption which causes the *diploë* gives rise to the formation of the cavities known as the frontal and sphenoid sinuses. The formation of the *diploë* divides the walls of the cranium into three layers—viz. an outer tough layer; an inner dense, brittle, and somewhat glass-like layer, known as the vitreous table or layer; and the intervening cancellous *diploë*. *Diploë* is absent from the cribriform plate of the ethmoid bone and from the roof of the orbital cavities, and thus these are the thinnest parts of the cranium. The growth of the skull after the seventh year proceeds slowly, but a slight increase goes on to about the age of twenty. The skull-bones are freely supplied with blood from arteries which pass from the dura mater internally and the pericranium externally, through the numerous foramina observed on both surfaces; the blood being returned by veins which take various directions.

The fact that concussion of the brain scarcely ever proves fatal, unless there is also fracture of the skull, affords the most distinct evidence that the skull is constructed in such a manner that so long as it maintains its integrity it is able to protect its contents from serious lesion. This marvellous protective power is due to its rounded shape, whereby its strength is increased, and in consequence of which blows tend to glide off it without doing material damage. Moreover, the curved lines or ridges which may be traced round the skull tend to strengthen it. The weakest part

of the skull is at the base. Hence, notwithstanding its removal from exposure to direct injury and the protection afforded by the soft parts, fracture takes place more frequently at the base than at any other part of the skull, fracture often taking place here even when the skull was not broken at the part struck. There are two points in the architecture of the bones of the face which deserve especial notice—viz. (1) the great strength of the nasal arch; and (2) the immobility of the upper jaw, which is fixed by three buttresses—the nasal, the zygomatic, and the pterygoid.

The base of the skull, whether seen from within or from below, presents many objects of physiological interest in relation to the nervous system. As seen from within, the base presents on each side three fossæ, corresponding to the anterior and middle lobes of the cerebrum and to the cerebellum. These fossæ are marked, as is the whole skull-cap, by the cerebral convolutions, and they contain numerous 'foramina' and 'fissures' which give passage to various sets of nerves and blood-vessels. The external or outer surface of the base of the skull, if we consider it from before backwards, is formed by the palate processes of the superior maxillary and palate bones; the vomer; the pterygoid and spinous processes of the sphenoid and part of its body; the under surface of the temporal bones; and the occipital bone. The most important of the parts which it presents are named at fig. 4.

The *Morphology of the Skull* is the highest and most difficult problem of comparative anatomy, and has cost the most extraordinary labour for its solution. Goethe and Oken independently suggested that the skull was to be regarded as the modification of a series of four vertebræ, and this 'vertebral theory' was worked out in the most elaborate detail by Owen and other anatomists (see *SKELETON*). Huxley, however, in a celebrated Croonian Lecture (1858), revised and extended the hitherto neglected embryological observations of Rathke, proposed an unanswerable destructive criticism of the archetypal theory, and may be said to have thus definitely placed the newer view in the way of general acceptance. An enormous amount of detailed research, for which we are indebted chiefly to Parker in England and Gegenbaur in Germany, has established the newer theory on the sure ground of actual observation.

Taking first the simple unsegmented cartilaginous cranium of a skate or dog-fish, with its appended jaws and branchial arches, we find that in development, though the notochord extends into the region

Fig. 4.—Base of the Human Skull :

- 1, 1, hard palate; 2, 2, palate bones; 3, vomer, 4, zygomatic fossa; 5, basilar process of the occipital bone, 6, foramen magnum; 7, foramen ovale; 8, glenoid fossa; 9, external auditory foramen, 10, carotid foramen of the left side, 11, styloid process, 12, mastoid process; 13, one of the condyles of the occipital bone.

of the head, the vertebræ stop altogether short of it; but that on each side of the cranium there arise a pair of cartilaginous bars—the *trabeculae* or 'rafters' of the future skull—and three pairs of cartilaginous capsules, nasal, ocular, and auditory, form round the developing sense-organs; the nasal capsules immediately unite with the ends of the trabeculae, which are meanwhile uniting below, and growing up at the sides to form the brain-case. The auditory capsules become united with the trabeculae by the appearance of two new masses of cartilage—the parachordals—the eyes of course remaining free. At first there are no jaws, but a series of seven or more similar vertical cartilaginous bars or arches, considerably resembling the trabeculae, between which slits open into the pharyngeal cavity. The first pair of these arches develops an ascending process, which passes above the developing mouth, and becomes the 'palato-ptyergoid' arch or upper jaw, the original portion remaining as the mandible. The second pair of arches—the 'hyoid'—becomes more or less modified usually to aid in supporting the jaws and floor of the mouth, while the remaining pairs become little modified, and serve throughout life to support the gills.

The more complex bony skulls of higher vertebrates are now in principle readily understood. The chondro-cranium and subjacent arches in all cases develop in the same way, although reduction and even atrophy of the gill arches subsequently takes place. The bones, although similar in the adult, originate in two utterly distinct ways, either by actual ossifications in the substance of the chondro-cranium and jaws, or by the ossification of overlying dermis, and are hence known as cartilage bones and membrane bones respectively—the latter corresponding to the dermal bones and teeth of ganoid and elasmobranch fishes. In mammals a further extraordinary specialisation takes place: the ends of the mandibular and hyoid arches lose their suspensory function, are taken up during development into the interior of the ear capsule, and are metamorphosed into the auditory ossicles.

Various Forms of the Skull.—Age.—At birth the existence of the fontanelles has already been referred to. The frontal and parietal eminences are especially prominent, and the mastoid process is absent. The face is only one-eighth of the bulk of the cranium, whereas in the adult the face is equal to one-half. During the first seven years the skull grows rapidly, and by this time many parts have attained definite size. At the period of puberty the face and regions of the air-sinuses undergo expansion. The face elongates owing to the growth of teeth and the increase in the size of their alveolar sockets. In old age the skull may become lighter and thinner or the reverse. Loss of the teeth and absorption of their sockets result in diminution of the size of the face, and thus the upper jaw recedes, while the chin becomes prominent.

Sex.—It is not always possible to determine the sex from the skull; but, as a rule, the skull of the male has more strongly marked muscular impressions, while the mastoid processes, superciliary ridges, and air-sinuses are more pronounced than in the female, whose skull generally retains the leading features of a young skull.

Race.—In comparing the skulls of different races of mankind it is necessary to have recourse to various methods of measurement, and these are usually conducted on the skulls of adult males. The following is a short summary of these methods. (a) *Cranial Capacity.*—This is obtained by filling the cranial cavity with shot, and then measuring the quantity in a graduated vessel, special precautions being observed in order to obtain equable results. The capacity of normal human crania

varies from 60 to 110 cubic inches—the average in all races being 85 cubic inches—e.g. Eskimo, 91.5; European, 90.3; Chinese and Mongols, 87.3; African Negroes, 82.4; Native Australians (aboriginal),

Fig. 5.—Typical Crania seen from the Vertex: a, Negro, index 70, Dolichocephalic; b, European, index 80, Mesaticephalic; c, Samoyed, index 85, Brachycephalic. (After Tylor.)

79.3; Andaman Islanders, 78.1. The average capacity of female skulls is 10 per cent. less than that of male skulls. (b) *Linear measurement of the horizontal circumference of the cranium.* In the adult European male the average is 20.7 inches, and in the female 19.6 inches. (c) A third method is by comparison of the relative *length, breadth, and height* of the cranium. The standard of maximum length is taken as 100, and thus $\frac{100 \times \text{breadth}}{\text{length}} = \text{index of breadth or cephalic index}$; and on this basis skulls are classified in three groups—viz.:

Brachycephalic = breadth-index above 80.
Mesaticephalic = " " from 75 to 80.
Dolichocephalic = " " below 75.

In a similar way the proportion of height to length may be calculated, and a *height-index* established. It varies less than the breadth-index—e.g.:

	Breadth	Height
Mongolians of Siberia and Central Asia.....	88	73
Andaman Islanders.....	82	77
Chinese.....	79	75
English.....	76	71
Native Australians (aboriginal).....	71	71
Fiji Islanders.....	66	74

(d) *The Degree of Projection of the Jaws.*—We have seen that the human skull, when compared with the skulls of lower animals, presents a small face extended vertically, and thus placed under the anterior part of the cranial box. Prominent jaws therefore indicate an approach to an animal type, especially when associated with a receding forehead. The degree of projection is expressed by

Fig. 6.—Lateral View of three typical Skulls: a, Australian, prognathous; b, African, mesognathous; c, European, orthognathous. (After Tylor.)

the *gnathic index* of Flower, and is obtained by comparing the basi-alveolar length with the basi-nasal length. When the gnathic index is below 98, skulls are said to be *orthognathous*; from 98 to 103, *mesognathous*; above 103, *prognathous*—e.g.:

	Gnathic Index.
English	96
Chinese	99
Esquimo	101
Fiji Islanders	103
Native Australians (aboriginal)	104

(e) The form of the nasal skeleton and its anterior openings is also subject to variation, and so its height and width may be measured, and the relation between the two expressed as a nasal index.

Nasal index below 48 = leptorhine.
 " from 48 to 53 = mesorhine.
 " above 53 = platyrhine.

For example:

	Nasal Index.
Esquimo	44
English	46
Chinese	50
Native Australians (aboriginal)	57

(f) In a similar way the form of the orbit is subject to variation, but this is of less consequence than the nose. Other measurements of the face skeleton are also made. A time-honoured measurement, long thought to be sufficient in itself for founding a classification of races, was the *Facial Angle* of the Dutch anatomist Peter Camper (q.v., 1722-89). This was obtained by drawing one line from the centre of the forehead to the most projecting part of the upper jaw just above the incisor teeth, and another from the opening of the ear to the base of the nasal opening; between these was contained the facial angle.

For the relation of craniometry to the science of man, see ETHNOLOGY and works there cited. Skulpin. See DRAGONET.

Skunk (*Mephitis*), a genus of small carnivorous quadrupeds of the family Mustelidæ. The body is elongated, and usually much arched; the tail long, and thickly covered with long, fine hair; the head small, with thick, blunt snout; the legs short, and the paws comparatively large, with five incompletely divided toes. The general colour is black and white. The power, characteristic in some degree of all the Mustelidæ, of forcibly discharging the fetid secretion of the Anal Glands (q.v.) is in the skunks enormously developed. All the species are American, and, as they differ little in habit, the Common Skunk (*M. mephitis*) may be taken as typical of the whole genus. The common skunk—an animal about the size of a cat—has fur of a glossy black; on the forehead is a patch of white diverging into two lines which extend the whole length of the back and meet again in the beautiful bushy tail. The under surface of the tail is also white, and, as it is usually carried erect or laid over against the body, the white is regarded by some naturalists as a 'warning colour.' Thus according to Belt: 'The skunk goes leisurely along, holding up his white tail as a danger-flag for none to come within range of its nauseous artillery.' The common skunk is found throughout North America, but is most abundant in the Hudson Bay region. It chiefly frequents high-lying, bushy, or even rocky districts and the banks of rivers, remaining concealed in its burrow by day, but emerging at dusk in search of the worms, insects, birds, and small mammals

which form its food. Its movements are slow and leisurely. It never attempts to run away if pursued, for, feeble and defenceless as it looks, it is

Common Skunk (*Mephitis mephitis*).

most efficiently protected by the possession of a nauseous fluid, the discharge of which neither man nor beast will wittingly provoke. Should an unwary intruder venture too near, the skunk turns its back, erects its tail, and, by means of a muscular contraction, ejects the contents of its anal pouches with a force which carries them to a distance of from 8 to 10 feet. So penetrating is the evil odour of this fluid that it is perceptible a mile off, and has been known to cause nausea in persons within a house with closed doors from which the animal was a hundred yards distant; and so persistent is it that clothes defiled by it can only be purified by prolonged hanging in smoke. It is said that the fluid has irritating properties which excite severe inflammation of the eyes, and cases are cited of Indians who have thus lost their eyesight. The skunk is hunted for its fur, which is in considerable demand; but the hunter must be careful to avoid alarming the animal, and thus causing it to discharge its obnoxious fluid. Skunks usually raise from six to ten young in a season. If taken young they are easily tamed and make pretty pets, for they are cleanly in habit and rarely emit their offensive secretion save when provoked. The Long-tailed Skunk (*M. macrura*) is found in central and south Mexico, and a much smaller species (*M. putorius*), with four white stripes, ranges from the southern states to Yucatán and Guatemala.

Sky. See ATMOSPHERE, CLOUDS, DUST, and METEOROLOGY.

Skye, an island of Inverness-shire, the second largest of the Hebrides, is separated from the mainland by a channel $\frac{1}{2}$ mile wide at the narrowest, Kyle Rhea. Its extreme length, south-south-eastward, is 49 miles; and its breadth varies from 7 to 25 miles; but on account of the extraordinary number of inlets at all parts of the island no point is above 4 miles from the sea. Area, 643 sq. m.; pop. (1841) 23,082; (1881) 16,889; (1921) 11,608. Skye is for the most part mountainous and moory, but it contains some pleasant tracts of arable and pasture land, and one considerable plain, formerly the bed of a lake, in the parish of Kilmuir, where some ruins of a religious house called after St Columba were found. The rocks are mainly volcanic of Tertiary age; and the principal mountains are the Coolin Hills (not Cuchullin), which stretch irregularly from south-west to north-east, terminating in the sharp peak of Sgurr-nan-Gilleann (3167 feet) above Sligachan. Another peak, Sgurr Dearg, has been found to be the highest of the range (3234 feet), but Sgurr-nan-Gilleann will still be regarded as the chief of the Coolin Hills. The serrated outline of these hills arrests the eye at a great distance, and forms the dominant feature in the view

at almost every point round the island, and far out at sea. The most famous scene in this region is Coruisk ($1\frac{1}{2} \times \frac{1}{2}$ mile), the 'stern, dread lake' of Scott's *Lord of the Isles*. Glen Sligachan, ascending $5\frac{1}{2}$ miles from the head of Loch Sligachan, is by many considered the grandest glen in the Highlands. The fantastic Quiraing (1779 feet) and the Storr (2360), in the north of the island, offer splendid scenery, as also do many points along the coast—here columnar basalt formations on a grand scale, and there cliffs 1000 feet high, over which leap many waterfalls, and whose bases are frequently worn into deep caves, some of them of historical interest. One, near Portree, afforded a refuge to Prince Charles Edward; another, on the west coast, was the temporary prison of Lady Grange. The largest arms of the sea are Lochs Bracadale, Dunvegan, and Snizort.

The coasts abound in fish, the most important being herring, salmon, cod, and ling; besides oysters are found in several places. The cod and ling fishery is chiefly confined to Lochs Dunvegan and Snizort. There are no rivers of any magnitude; but salmon and sea-trout are got in some of the principal streams, and trout in most of the fresh-water lochs. Deer are not numerous, nor grouse. West Highland cattle are reared to a considerable extent, but sheep-farming on a large scale predominates. The rainfall averages 65 inches, but the climate is mild and healthy. Agriculture in Skye, being comparatively unprofitable, owing to the moisture of the climate, is falling into entire neglect on some of the chief sheep-farms. The soil, however, is in many places excellent, and capable, in dry seasons, of yielding good cereal crops, while for turnips it is peculiarly suited.

The inhabitants are for the most part poor and ill-housed, but well-behaved and intelligent. At one time they contributed largely to the British army—not less than 10,000 private soldiers, it has been calculated, during the long war with France. The number of soldiers now sent from Skye is very small. In the districts where the men practise fishing nearly the whole of the adult males go to the east coast fisheries in summer, while from all parts of the island young men and women go to the south in search of field-labour. Potatoes and fish are the general diet, meat being a rare luxury. The population is chiefly Celtic, with, however, a considerable Norse admixture. Gaelic is still universally spoken, but is gradually giving place to English. Lord Macdonald's seat, Armadale Castle in Sleat, is one of the most beautiful in all its surroundings to be seen on the Scottish coasts. At Macleod of Macleod's ancient castle of Dunvegan, perched on a headland, Dr Johnson 'tasted lotus' (1773) and Scott slept in the 'Fairy Room' (1814). The principal port of Skye is Portree, a picturesquely situated village of 900 inhabitants, to which steamers regularly ply from Glasgow, and from Kyle of Lochalsh and Mallaig, in connection with the Skye Railway and Mallaig Railway. Other villages, also calling-points of the steamers, are Kyleakin ('Hakon's Strait'), Broadford, and Dunvegan. 'Talisker' whisky is made at Carabost at the head of Loch Bracadale. Diatomite is found in Trotternish, and manufactured for explosives. A seam of oil-shale was discovered in 1913. In 1926 the splitting up into small holdings of the whole of the Macleod estate was completed.

See Alexander Smith's *Summer in Skye* (1865); Robert Buchanan's *Hebridean Isles* (1883); J. A. Macculloch's *The Misty Isle of Skye* (1905); and for mountaineering, *Island of Skye* (ed. Steeple, Barlow, and Macrobert, 1923).

Skye Terrier, a breed of dogs supposed to be the outcome of a cross between the native dog of Skye and a Maltese terrier, landed from a passing

ship—a statement difficult to believe and impossible to prove. Though long known in Scotland, where he was in some places used as a working terrier, it is only of late years that the Skye terrier has

Skye Terrier.

become common over the whole of England. The chief beauty of the Skye is its long and graceful coat, which requires so much attention that it is better suited for a town life than a country one. In its proper place, the Skye is a bright and cheerful companion. The modern Skye should be very low at the shoulder, not above 9 or 10 inches high, with as long a body as possible; many good specimens measure 40 inches from nose to tip of tail. The coat should be very long and abundant, nearly touching the ground, but hanging quite straight, without any curl. Colour varies from a dark blue to a light gray. The weight should be about 20 lb. The Skye terrier is divided into two varieties, Prick-eared and Drop-eared. Though many admirers claim working properties for the Skye, as now bred, it should only be regarded as an ornamental dog. The Paisley or Clydesdale terrier is a Skye with a light-coloured and silky coat, and is kept entirely as a house-dog.

Skyros, or **Scyro**, an island of the Grecian Archipelago, the largest of the northern Sporades, 24 miles N.E. of Eubœa. Length, 17 miles; area, 79 sq. m. Skyros is very mountainous in the south, the mountains being covered with forests of oaks, firs, and beeches; but the northern part, though also hilly, has several fertile plains, which produce fine wheat and grapes for wine. The only town is Skyro, or St George, on the east coast. This island is associated with the legends of Achilles and Theseus. In 469 B.C. Cimon the Athenian conquered it and carried off to his native city the bones of the hero Theseus. It was likewise celebrated for its goats and its variegated marble. Rupert Brooke was buried here in 1915. Pop. about 3500.

Slade, **FELIX** (1790–1868), of Halsteads, Yorkshire, was an antiquary and art collector, and bequeathed to the British Museum his valuable collections of engravings and of Venetian glass. He also left by will money to found art professorships at Oxford, Cambridge, and at University College, London. Amongst Slade professors have been Ruskin, Sidney Colvin, and W. B. Richmond.

Slags, sometimes called *Scoriae*, are fused compounds of silica with lime, alumina, and other substances. Blast-furnace slag is usually little else than a silicate of lime and alumina. In smelting processes the slag floats on the top of the molten metal, and is run off or raked off as 'waste material,' provided that the metal has been practically all

extracted from it. Many slags which were thrown away in early times have been profitably smelted again in modern days, owing to the amount of metal left in them. Some slags form an opaque glass, but other varieties are more stone-like in appearance, while some are beautifully crystallised. In Great Britain many millions of tons of iron blast-furnace slag are annually produced. Until comparatively recent times this was considered useless material, but it is now utilised in several ways. By the action of steam upon it in the melted state it is made into fine threads or filaments called 'slag wool' or 'silicate cotton.' This is a bad conductor of heat and sound, and is used as a covering to boilers, and to prevent sound passing through floors. It is also employed for fireproof netting. In some cases blast-furnace slag has been made into serviceable bricks and large blocks for building, as well as into paving sets. On the Continent a useful building cement, or substitute for mortar, has been made from it. The slag from the manufacture of steel from Cleveland pig-iron by the basic process contains about 17 per cent. of phosphoric acid, and forms a valuable fertiliser for sour, peaty, and clay soils.

Slander is an injury to a person's character and reputation caused by spoken words, or in some other fugitive form such as sounds, looks, signs, or gestures. It is to be noticed that oral unlike written defamation is only actionable (1) on proof of actual, or, as it is technically termed, special damage; (2) in the following specific cases: (a) statement that the plaintiff has committed a criminal offence, (b) an assertion that he is suffering from an unclean and contagious disease, (c) defamatory words spoken in the way of his business or profession. To impute unchastity to a woman was not in itself actionable unless (it is said) the words were spoken in London, when by the custom of the city an action would lie thereon; but the Slander of Women Act (1891) makes the mere imputation a ground of procedure. The remedy for slander is an action at law for damages. To prove the truth of the alleged slander is a complete answer, and the defence of privilege may also be set up. The criminal law affords no protection against slander, nor will any 'indictment lie for mere words not reduced into writing, unless they be seditious, blasphemous, grossly immoral, or uttered to a magistrate in the execution of his office, or uttered as a challenge to fight a duel, or with an intention to provoke the other party to send a challenge.' This radical distinction between written and spoken defamation is not recognised in Scots law. See LIBEL, TORT; Odgers, *The Law of Libel* (1911); Sir F. Pollock, *The Law of Torts* (12th ed. 1923); Gatley, *Law and Practice of Libel and Slander in a Civil Action* (1924).

Slang embraces not only peculiar jargons or dialects, such as Gypsy, Canting or Flash, Back-slang, and Shelta or Tinkers' Talk, but also a vast number characteristic of trades, pursuits, and positions in every class of society; so that we may agree with Professor A. Barrère, that perhaps the best general definition at which one can arrive is that 'Slang is a conventional tongue with many dialects, which are, as a rule, unintelligible to outsiders.' In its extended sense it is difficult to draw the line between technical terms—as for instance those used on the turf or in sport—and slang, especially when equivalents for them are wanting in correct English. Any kind of shibboleth used to distinguish a class, be it of students, clergymen, authors, or the most fashionable circles, is correctly called slang.

The chief elements of all slang consist first of absolutely foreign words, including those manu-

factured; as when a costermonger says 'molty kerteever,' from the Ital. *molto cattivo*, for 'very bad,' or a street-vagabond uses the Romany *lelled* ('taken'), for 'arrested.' The other is the substitution of English words for equivalents, as when we hear 'brass' for impudence, 'timbers' and 'pins' for legs, 'claret' for blood, and 'tile' for a hat. Thus it is often rough metaphor or poetry. 'A certain proportion of slang words after performing, as it were, quarantine, receive a clean bill of health, and are admitted to that great port the dictionary.' Some make a reappearance in recognised language. Thus *humbug* was long treated as pure slang, but is now generally used even by the most correct writers. Very little slang is to be found in Greek or Latin (though Aristophanes and Martial often approach it), or in any European language until the middle ages. François Villon (15th century) wrote ballads in an *argot* which was by far the most copious and perfected in Europe. In Germany *Kotwalsch* (*walsch*, 'foreign' or 'Italian'; *rot* being either from *rot*, 'red,' or *rotte*, 'a gang') can be traced back to the 13th century. Martin Luther wrote a preface to a dictionary of the jargon used by the thieves of his time, in which half the words are Hebrew, derived from the receivers of stolen goods and their Yiddish dialect. In Italy there was a *lingua furbesca*; and in Spain the *Tumanesteca* which was largely mixed with Spanish Gypsy, itself a very much corrupted Romany. English Canting, or the language of the dangerous and vagabond classes, which in a great measure preceded all other forms of slang, did not before the end of the 15th century embrace more than 150 or 200 words. Harman, a magistrate who in 1567 published a vocabulary of Slang or Canting, declares explicitly that it was only within thirty years of his time of writing that the dangerous classes had begun in England to use a separate language at all.

Shelta (q.v.) is spoken by tinkers. Shakespeare, it should be noted, makes Prince Hal speak of a tinker's language. *Yiddish* (Ger. *Jüdisch*, 'Jewish') is a strange compound of very corrupt Hebrew and ancient or provincial German, spoken by Jews. It is extensively spoken in the East End of London. It is in Germany a language of some importance. Hotten was the first to show and illustrate the curious fact that among street-musicians and costermongers a very corrupt and singular form of Anglo-Italian had become current. Still more strangely, it has come to be considered by tramps as the lowest and most vulgar means of expression. The keeper of a tramps' lodging-house after hearing a Cambridge professor speak Gypsy and Tinkers' Slang made no remark, but hearing him speak Italian said, 'Well, I'd never a-supposed you'd been down as low as that.'

The Dutch language during the time of the Georges contributed a good many words, such as *boeser*, 'a buffer'; *blunk*, 'to drink.' In America a still greater number was derived from this source (e.g. sleigh, from *slé*), which have since come over to England. Some confusion has resulted from the fact that owing to its great resemblance to other northern languages philologists have often thought they had discovered in English slang words of Saxon or Danish origin which were really Dutch, and often Dutch slang. There still remains much to be done as regards investigation in this field. About the beginning of the 19th century, when there was much attention paid to such subjects, and many fast or fashionable men affected to be familiar with vulgar life, there sprang up, it is said, about Leadenhall in London, and bearing that name, that which was afterwards known as Back-slang. This consisted of words spelled backwards, such as *top* for *pot*, *yennep* for *penny*, *nig*

for gin—a device not unknown in 'Nodnol' in earlier times. Many traces of it are to be found in the gay novels and memoirs of the thirties and forties. Contemporary with it in origin is rhyming slang—i.e. the employment of a word which loses its own signification, taking that of another with which it rhymes. Thus *Lord John Russell* means *bustle*, a canting term meaning to pick pockets, also money. *Romany* or *Gypsy*, *Shelta* or *Tinkers' Talk*, *Canting* or *Kennick*, also known at one time as *Flash* or *Thieves' Latin*, form the principal English slangs. All have their dialects or local differences. Thus, the *Shelta* heard in tramps' London lodging-houses is a very much corrupted form of that which is spoken in Scotland. Slang may consist of mere intonation or pronunciation: thus, *Hotten* gives the use of 'Gawd,' or 'Gorde,' for God, and the like by certain clergymen as pulpit slang. There are in America preachers who carry this to such an extent that they have almost formed a language of their own in this way; and a certain bishop was once declared to be in the habit of saying in the pulpit: 'He that hath *yaws* to *yaw*, let him *yaw*,' while in ordinary life he said plainly enough: 'He that hath ears to hear, let him hear!' The misuse of certain French terms is also slang, which is, however, returned a hundredfold by the rather recent adoption and abuse of English words by Parisians, who, for example, believing that *five o'clock* means to drink tea, have formed the remarkable slang verb *fiveocloquer*, and even say *Fiveocloquons-nous à quatre heures*? Parliamentary, military, sporting, legal and literary, stage, showmen's, shopkeepers', and stock-exchange slang, and that of different callings or trades are all extremely interesting, since there is not one that has not many very old words, often of Norse or Celtic origin, which have not as yet been much investigated. One of the most prolific sources of slang of late years has been the American. This has for a 'stem' obsolete English and provincial terms which have been retained chiefly in New England and the West, and which are really not slang, though so called. To these may be added words of German, Dutch, Canadian, French, Red Indian, Negro, and Spanish origin. The Great War caused many Anglo-Indian and other words to pass from soldiers' slang into current use.

The principal works on this subject are Harman's *Caveat for Common Corsetors, vulgarly called Vagabones* (1566); the *Life of Bamfylde Moore Carew* (no date), containing a vocabulary of Canting mis-called Gypsy; Grose's *Dictionary of the Vulgar Tongue* (1785); *Bacchus and Venus* (1737), with a canting vocabulary republished as the *Scoundrels' Dictionary*. (This dictionary is said to have appeared by itself in 1710 as *A Dictionary of the Canting Crew*.) The first work of any value on this subject in which slang was treated in its true sense was the *Slang Dictionary* of John Camden Hotten (1859). Professor A. Barrère and Charles Godfrey Leland's *Dictionary of Slang, Jargon, and Cant* contains Americanisms, Gypsy, Shelta, Pidgin English, Anglo-Indian, and other terms, with a history of English slang (2 vols. 1885; new ed. 1897). John S. Farmer and William Ernest Henley's *Slang and its Analogues* is a monumental work in seven volumes (1890-94), and the same authors' *Dictionary of Slang* is abridged therefrom (1 vol. 1905). See also M. A. Mugge, *Dictionary of War Words* (1920) and P. L. Jaeger 'On English War-Slang' in *Englische Studien* (1926). For American slang, see F. N. Scott, *American Slang* (1926); and AMERICANISMS. Gypsy: see works of George Borrow, *Lavengro*, *Romany Rye*, &c., and *Dialect of the English Gypsies*, by Dr Bath Smart and Crofton (1863-88). See also the articles GYPSIES and SHELTA, with works there cited. Anglo-Indian: Sir Henry Yule and A. Brunell, *Glossary of Anglo-Indian Colloquial Words and Phrases* (1886). Pidgin English: *Pidgin English Ballads*, with vocabulary of the Jargon, by Charles G. Leland (1886). French

Slang: Barrère, *Argot and Slang* (Lond. 1887); and books on slang of the 19th century by Rigaud (1881) and Sainéan (1920), and of the 20th century by Bauche (1920) and Leroy (in Eng. 1922). German Slang: *Avé-Lallemant, Deutsches Gaunerthum* (1862); Genthe, *Deutsches Slang* (1892); a book by Delcourt (in Fr. 1917); Kluge, *Rotwelsch* (1901); Gunther, *Die deutsche Gaunersprache* (1919).

Slate, or CLAY-SLATE (Fr. *esclat*, a 'shiver' or 'splinter'), is a highly metamorphosed argillaceous rock, fine-grained and fissile, and of a dull blue, gray, purple, or green colour. A red slate is found at Acton, Quebec. Slate splits into thin laminæ or plates, that are altogether independent of the layers of deposit; though sometimes coinciding with them, they more frequently cross them at different angles (see CLEAVAGE). Some rocks that split into the thin plates of the original stratification are popularly but erroneously named slate, as thin bedded sandstones properly called flagstones or tilestones, sometimes used for roofing. True slate is a very compact rock, little liable to be acted upon by atmospheric agencies. It is chiefly obtained from Palæozoic strata, but it is found also among more recent rocks. It is used for various purposes, being split into thin slabs of small size for ordinary roofs and into larger slabs for dairy fittings, wash-tubs, cisterns, tables, &c., and, when polished, for writing-slates and 'blackboards.' School slates are manufactured in very large numbers in Wales. They are split, like roofing-slates, by hand; but the sawing, grinding, and polishing processes are done by machinery: the making of the wood frames for them being also done by machines. In the United States slate is used for grave-vaults and for tombstones. Increasingly large quantities are being quarried for electrical purposes, particularly in Maine and Vermont. There are extensive quarries of roofing-slate in Wales and Scotland, and in the Ardennes in France, some of which have been wrought for a long time. For some years previous to 1891 the average annual quantity of slates quarried or mined in England and Wales amounted to about 450,000 tons (value one million sterling); in 1922 only 222,139 tons were quarried, but the value was nearly two million sterling. Among the great slate-quarries there may be mentioned those of Penrhyn (near Bethesda), Llanberis, and Festiniog. Considerable but much smaller quantities are produced in Ayrllshire in Scotland and in some counties in Munster, Ireland. Welsh slates are largely exported to Germany and Australia. Pennsylvania is by far the largest slate-producing state in the United States of America, but Maine and Vermont both outrank it in the production of electrical slate. In recent years there has been a remarkable increase in America in the output of slate 'granules' used principally as a surfacing material for manufactured roofing. Pulverised slate or 'flour' is used as a filler in roofing mastic, in road asphalt, and also in rubber, oilcloth, and linoleum.

In roofing with slates it is necessary to put them on in two thicknesses, so that the sloping joints may be covered by the overlap of the course above. Besides this, the third course must also cover the first by an inch or two, to prevent rain from penetrating. Slates are generally laid upon boarding, and bedded in lime, and nailed with malleable-iron nails, galvanised, so as to prevent them from rusting. When large strong slates are used

they may be nailed to strong laths in place of boarding. Welsh slates are the smoothest and most generally used; but Argyllshire slates are stronger and better when the roofs are liable to be injured.

Slate-pencils are either cut or turned sticks of soft slate, or they are made by pressing moistened slate powder until it is firm enough to be made into pencils.

Slaughter-houses, or ABATTOIRS.—The public abattoir for slaughtering and preparing animals for food originated in France. On the report of a commission, Napoleon decreed their construction for Paris, and between 1807 and 1818 five were built. So pleased was he with the first completed in 1810 that he further decreed that abattoirs should be established in all large and medium French towns. Since then the idea has been adopted by all the advanced European nations. Edinburgh had a good abattoir in 1851, replaced in 1910 by a larger one on a new site. London's first public abattoir, opened in 1855, was at the Islington market. In later times very many abattoirs have been built or rebuilt in this country, and the newer ones are frequently very fine in design, style, and equipment. The finest abattoirs, however, are to be found in Germany.

The general requirements to be aimed at in a modern slaughter-house are as follows. The site should be open and roomy, and where land is not too expensive. Good drainage and a plentiful supply of pure water are essential. Transport arrangements in the way of roads and railways should be ample. The convenience of the position for dealers, butchers, and other users requires consideration. As far as possible the buildings should be in separate blocks to secure abundance of light and of ventilation, and sound sanitary conditions. Materials should be stone, brick, or reinforced concrete, and iron columns, beams, and roof framing.

The first department of a slaughter-house is that of lairage and pennaage, where the animals are placed to await slaughter. The lairs and pens are made of iron or steel bars or tubes fixed in cast-iron columns set in a concrete floor with chequered tiles on top sloped to central passage-ways; a roof over is now generally provided. The position is adjacent to the slaughter-houses for cattle, pigs, and sheep, which, if possible, should be in different buildings.

The equipment for cattle-slaughtering consists of killing rings or pins, to fasten the animals to for stunning by either the pole-axe or the automatic pistol; hand safety wall-hoists and gambrels to hoist the beasts for bleeding, skinning, and dressing; and runways with wheel-travellers 12 feet above the floor to take the split and dressed sides of beef. Sheep and calves are killed on stands, or 'cradles,' and dressed, suspended to hooks on side rails. Pigs are hoisted—stunned or otherwise—to bleeding-bars, from which they are pushed on to a bench and rolled into a scalding-tank, from which they are lifted by a lever-cradle on to a scraping-bench, and then hoisted to overhead tracking for dressing.

From the slaughter-houses the dressed sides generally pass to hanging-halls to be air cooled and dried, and from these either to the delivery-doors or the cold rooms, if not required at once. These departments are connected by overhead runways with wheel-travellers, the hangers being arranged so that the travellers can pass them. The side lines are joined up to the main track by switches, and wheel hooks with their loads can pass to and from any part of the system. Insulated cold rooms, cooled by refrigerating machinery, are a feature of all modern abattoirs, where the meat can be stored or 'matured' until required.

For dealing with diseased or suspected animals a small lairage and slaughter-house is provided away from other buildings, and a dissecting-room should be added for the convenience of the inspectors. The offal department should adjoin, where diseased meat and other waste animal-matter can be sterilised and worked up into tallow and meat meal, the equipment consisting of a steel steam digester, tallow separating and settling tanks, steam drier for digested meat, offal, and blood, and a grinding-mill.

Engine and boiler houses are required to supply power and steam to the refrigerating machinery and offal plant, and hot water to the slaughter-houses. Other subsidiary departments frequently built or rented by private firms or individuals deal with the cleaning of tripe, the melting or rendering of fats, the preparation of skins or hides, the cleaning of the entrails for sausage casings, and the working up of hoofs and horns.

The administrative buildings and offices, staff restaurant where provided, accommodation for inspectors, dealers, and butchers, are usually placed near the main gates, and these buildings give the architect his opportunity. In Germany they are frequently very ornamental, and placed in grounds laid out with flower-beds, shrubs, and trees.

The European abattoir, as a rule, is built in one story, all the principal operations being conducted on the ground floor. Sometimes there is an extensive cellarage for the accommodation of machinery, the salting of hides, &c., and some of the subsidiary departments may have two floors, but the ground-floor idea is adhered to wherever practicable. In the United States, where there are very few public abattoirs, most of the slaughtering business being in the hands of the packing companies, the practice is quite different. The packing-house arose out of American conditions. Cattle were cheaply reared on the great western plains and dressed meat required in the more populous east. The great distances between made it uneconomical to send small consignments of beasts to butchers. The offal, on which packers have always largely relied for their profit, was mostly wasted. Private enterprise evolved the idea of large central slaughtereries and manufactories in which every part of the animal would be used to the best advantage, and the experiment was started at the great stockyards of Chicago. Success was not immediate, but the rise of refrigeration solved the chief difficulties. Cold storage and iced and insulated railway trucks enabled the packers to deliver fresh meat all over the Union and, with refrigerated ships, ultimately to England and other places overseas.

Packing-houses vary greatly in design—there has been continuous development—but on one point they nearly all agree. They are tall buildings, four or six stories high, with cellarage in addition, and the beasts to be slaughtered travel on foot up a ramp or inclined way to the top stories where the slaughter-houses are situated. This gives the advantage of gravitation for subsequent handling, hand-friction 'droppers' being used instead of mechanically operated hoists. The offal is shot through shutters to the floors below the slaughtering stories. In the later plants the department blocks are separate, with as many as four to six railway sidings between them. Connection with the cold-storage block is made by bridges or covered ways on the level of the slaughtering floors, and from the offal floor to the tankage-block where blood, bones, hoofs, horns, and other inedible material are worked up into tallow, manure, poultry food, materials for button-making, &c. The refrigerating department is on a very large scale, for it has not only to accommodate great quantities of fresh meat but also to

provide large spaces for the curing of hams and bacon.

The rendering of fats into oleo for margarine-making, 'kettle' rendered lard, and prime steam lard is conducted on the two floors under the offal floor, the ground floor being used for storage of the products, and the cellars underneath for salting and storing skins and hides. The stockyard or lairage is at the rear of the factory, with further lairs on the slaughter-house level. The offices, sausage-making and smoking departments, ice-making plant to supply ice for insulated meat trucks, together with the boiler and power houses, may be at the front of the factory, where there should be a good road.

It would take too much space to describe in detail the great variety of ingenious machinery used in packing-houses. It is constantly being altered and improved. The 'string-gang' is greatly used in the slaughtering departments. The carcasses mechanically propelled on overhead runways pass before a line of men, each of whom does a small part of the dressing, and a very large number of animals are killed and dressed in the most economical way in a relatively small space. The aim of the packing-house is to utilise everything. The great chemical laboratories of the largest packers make rennet and pepsin, and extracts of the thyroid, pituitary, and many other glands, which are used in medicine all over the world.

Slave-coast, a division of the coast of Upper Guinea, Africa, extending eastwards from the Gold Coast through Togoland, Dahomey, Lagos to the river Benin in Nigeria.

Slavery, in the fullest sense of the term, implies that the slave is the property or at the disposal of another, who has a right to employ or treat him as he pleases; but the system has been subjected to innumerable limitations and modifications. Slavery probably arose at an early period of the world's history out of the accident of capture in war. Savages, in place of massacring their captives, found it more profitable to keep them in servitude. All the ancient oriental nations of whom we have any records, including the Jews, had their slaves. The Hebrews were authorised by their law to possess slaves, not only of other races, but of their own nation. The latter were generally insolvent debtors who had sold themselves through poverty or thieves who lacked the means of making restitution; and the law dealt with them far more leniently than with stranger slaves. They might be redeemed, and if not redeemed became free in the space of seven years from the beginning of their servitude; besides which there was every fiftieth year a general emancipation of native slaves.

Greek Slavery.—In the Homeric poems slavery is the ordinary destiny of prisoners of war; and the practice of kidnapping slaves is also recognised—Ulysses himself narrowly escaping a fate of this kind. None of the Greek philosophers considered the condition of slavery objectionable on the score of morals, though they desired it to be humane in practice. Aristotle maintained that some men were born inferior, and were therefore slaves by nature; while Plato only desired that no Greeks should be made slaves. One class of Greek slaves were the descendants of an earlier and conquered race of inhabitants, who cultivated the land which their masters had appropriated, paid rent for it, and attended their masters in war. Such were the Helots in Sparta, the Penestæ in Thessaly, the Bithynians at Byzantium, &c., who were more favourably dealt with than other slaves, their condition somewhat resembling that of the serfs of the middle ages. They could not be sold out of the

country or separated from their families, and were even capable of acquiring property. Slaves obtained by purchase were the unrestricted property of their owners, who could dispose of them at pleasure. In Athens, Corinth, and the other commercial states they were very numerous, and were mostly barbarians. They were employed partly in domestic service (some being *pædagogoi*, employed to accompany boys to school, &c.), but more as bakers, cooks, tailors, or in other trades, in mines and manufactories, as labourers on country estates, and as seamen and oarsmen; and their labour was the means by which the owner obtained profit for his outlay in their purchase. These slaves were for the most part purchased; but many were born in their master's family. The Athenian state employed public slaves as police, as soldiers, public criers, gaolers, &c. An extensive traffic in slaves was carried on by the Greek colonists in Asia Minor with the interior of Asia; another source of supply arose from the practice common among Thracians and Scythians of selling their children. In Greece in general, and especially at Athens, slaves were mildly treated, and enjoyed a large share of legal protection. According to Demosthenes, a slave at Athens was better off than a free citizen in many other countries. Manumissions were possible. A master could obtain damages if a slave was maltreated. The slave was not allowed to wear his hair long, was prevented from entering the gymnasia and public assemblies, but had access to temples and festivals. It has been estimated that in the palmy days of the Athenian state there were as many as 400,000 slaves in Attica; about three times the number of freemen.

Roman Slavery differed in some particulars from that of Greece. All men were considered by the Roman jurists to be free by natural law; while slavery was regarded as a state contrary to natural law, but agreeable to the law of nations, when a captive was preserved, instead of being slain (the name was believed on doubtful etymological grounds to be '*servus*, quasi *servatus*'); or agreeable to the civil law, when a free man sold himself. In earlier times there was no restriction on the master's power of punishing or putting to death his slave, which was generally carried out by crucifixion; and even at a later period, when the law on this head was much modified, slaves were used with great rigour. The estimation in which their lives were held is illustrated by the gladiatorial combats. Old and useless slaves were often exposed to starve in an island of the Tiber. Under Sparta-cus (q.v.) a rebellion of slaves attained alarming dimensions. In the time of the empire the cruelty of masters was in some degree restrained by law. It was enacted that a man who put to death his own slave without cause should be dealt with as if the slave had been the property of another; and that if the cruelty of the master was intolerable he might be compelled to sell the slave. Slaves could contract a kind of marriage called *Contubernium*; and ultimately this relation was regarded as indissoluble. The children of a female slave followed the status of their mother. There were various ways in which a slave might be manumitted, but the power of manumission was restricted by law. The harbouring of a runaway slave was illegal. The number of slaves in Rome, originally small, was increased much by war and commerce; and the cultivation of the soil came in the course of time to be entirely given up to them. During the later republic and empire persons in good circumstances kept an immense number of slaves as personal attendants; and the possession of a numerous retinue of domestic slaves was matter of ostentation—200 being no uncommon number for one person.

A multitude of slaves were also occupied in the mechanical arts and the games of the amphitheatre. Originally a slave was incapable of acquiring property, all his acquisitions belonging to his master; but when slaves came to be employed in trade this condition was mitigated, and it became the practice to allow a slave to consider part of his gains, called his *peculium*, as his own, a stipulation being sometimes made that he should purchase his freedom with his *peculium* when it amounted to a specific sum. Having no legal standing, a slave could not give evidence.

Though the introduction of Christianity did not do away with slavery, it tended to ameliorate the condition of the slave. The fathers taught that the true slavery is not that of the body, but the slavery of sin; and Chrysostom thought the apostle did not insist on the suppression of slavery because it was desirable that men should see how truly the slave could enjoy liberty of soul. Constantine allowed poor parents to sell their children into slavery. Justinian, though his Constitutions (529 A.D.) drew a very sharp line between slaves and freemen, did something to promote the eventual extinction of slavery; the church excommunicated slave-owners who put their slaves to death without warrant from the judge. But it was not till the reign of Basil (867-886) that the slaves' *contubernium* was hallowed by the blessing of the church. The number of slaves again increased; multitudes being brought with them by the barbarian invaders, who were mostly Slavonic captives (whence our word *slave*); and in the countries which had been provinces of the empire slavery continued long after the empire had fallen to pieces. In the Germanic societies there were a few slaves proper, captives in war and the like, but the basis of the Village Communities (q.v.) was the tenants paying rent and holding land under the free. In Britain great numbers of the Celtic natives were enslaved by the Anglo-Saxons; and the Christian Anglo-Saxons had a regular trade with the Continent in Irish slaves, Bristol being a great slaving port. After the Norman Conquest slaves as in a separate class almost ceased to exist, and slavery eventually merged into the mitigated condition known as serfdom, which prevailed all over Europe in the middle ages, and has been gradually abolished in modern times. But though the practice of selling captives taken in war as slaves ceased in the Christian countries of Europe, a large traffic in slaves continued among Mohammedan nations, by whom Christian captives were sold in Asia and Africa; and in the early middle ages the Venetian merchants traded largely in slaves, whom they purchased on the coast of Slavonia, to supply the slave-markets of the Saracens. The history of the achievements of the Barbary corsairs is not to the glory of the Christian nations of Europe. These professional sea-robbers continued for centuries—down to 1812, indeed—to harry the coasts and the commerce of Europe, carrying large numbers of Christians into all but hopeless captivity. When Cervantes was for five years a slave he had about 25,000 fellow-captives in Algiers alone, some treated fairly well, some with great barbarity. Cervantes was ransomed for about £100; £30 or £40 was a more usual price. Another famous slave was St Vincent de Paul. The order of Trinitarians (q.v.) was founded in 1198 for the purpose of redeeming captives (especially French) out of the hands of the infidels, sometimes bringing away several hundreds at a time; and in the 18th century it was not unusual in English and Scottish churches to make collections for a like purpose (see *CORSAIR, GALLEY*). Christians sent to the galleys by their own or foreign authorities were worse off than domestic

slaves. English convicts used to be transported to what was practically slavery in His Majesty's Plantations (see *PRISONS*); and convict labour is still a kind of judicial slavery for life or a term of years.

Serfdom.—A numerous class of the population of Europe known as serfs or villeins were in a state of what was almost tantamount to slavery during the early middle ages. In some cases this serf population consisted of an earlier race, who had been subjugated by the conquerors; but there were also instances of persons from famine or other pressing cause selling themselves into slavery, or even surrendering themselves to churches and monasteries for the sake of the benefits to be derived from the prayers of their masters. Different as was the condition of the serf in different countries and at different periods, his position was on the whole much more favourable than that of the slave under the Roman law. He had certain acknowledged rights—and this was more particularly the case with the classes of serfs who were attached to the soil. In England, prior to the Norman Conquest, a large proportion of the population were in a servile position, either as domestic slaves or as cultivators of the land. The humblest was nearly a slave—the *theow*; the other the *Coerl* (q.v.), an irremovable tiller of the ground. The powers of the master over his serf were very extensive, their principal limitations being that a master who killed his serf was bound to pay a fine to the king, and that a serf deprived of his eye or tooth by his master was entitled to his liberty. And English serfdom was always territorial rather than personal. After the Norman Conquest there were various names used for the serfs, who seem ultimately all to have been confounded in one class, though originally different. The *villein* (*villanus*) was the Anglo-Saxon *coerl*; he could also be an Anglo-Saxon small free landowner, depressed by the Conquest. The villeins were the tenants among whom the ploughlands of the township were chiefly distributed, each villein being supposed to have on an average, a *virgate*, i.e. 30 acres of arable *plus* right of pasture. The *cottier* (*cotarius*) or *bordarius*, also an agricultural labourer, had no share in the arable, and was less favourably situated; he might only have a cottage and garden, and no plough or oxen, and might even work for some of the richer villeins. The distinction between a *villanus* (or *rusticus*) and a *cotarius* (or *nativus*) was, however, always maintained in the rolls, but the 14th-century terms, *villeins regardant* and *villeins in gross*, only referred to different ways of proving villeinage in a law-court. There are *servi* mentioned in Domesday Book, but they are few in number, and have disappeared by the 12th century. In strict legal theory all the villein's chattels were his lord's and could be confiscated if the occasion warranted it; he had to do whatever he was bid; he never knew what the morrow's work would be; he could not leave the manor to which he was attached; he was excluded from bearing arms; he could not sit as recognizer in the shire or hundred court; and there were disabilities against him entering the church. In actual practice, however, much of this breaks down. Every shade and local variation of dependence appears, and the definitions of Bracton and other 13th-century lawyers are often artificial and inconsistent. The manor rolls show that villeinage rested on tenure rather than status, and that villein tenure (as opposed to freehold) implied agricultural service (not rent). A freeholder could occupy a villein tenement, and the distinction lies between *villanus* and *liber tenens*; Magna Carta includes both in most of its general provisions, e.g. 'nulli' (sect. 40), 'homines' (sect. 44). A villein was never a personal slave, but only a villein with reference to some particular manor, and, in fact, did practically

own property (cf. *Magna Carta*, sect. 20, which protects his plough-team even against the crown itself). Enfranchisement was possible by purchase, taking orders (despite legislation on the subject), or residing in a borough for a year and a day. At times they were definitely entrusted with aims; and the uncertainty of service was probably much exaggerated, while in the manorial court they were self-governed, besides being in frankpledge. The complete independence of the villeins, which fitted into the schemes for parliamentary representation (with the theory that 'taxation requires consent'), and which coincided with the substitution of royal writ for feudal tenure, was hastened on and consummated by economic forces. The development of taxation, the spread of trade, the crusading movement, all helped to make money in demand, while even from the beginning there had been a strong impulse to commute services into money as a matter of convenience. Every alienation of demesne implied diminished need of labour on it, and the increase of population meant there were plenty of men to be hired for money when the bailiff wanted it. Just as the food-payments of Saxon and early Norman times passed into the labour services of the 12th and 13th centuries, so the labour services became commuted into money-rent under the three Edwards. Seven years of bad harvests at the beginning of the 14th century, the Black Death (q.v.), and the Peasants' Revolt of 1381 made commutation universal. The villein became the yeoman or small farmer, while conveyance by feoffments came to be the test of freehold. Serfdom lingered on in places, however, for we find a commission issued in 1574 by Queen Elizabeth, to inquire into the lands and goods of all her bondsmen and bondswomen in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy all their lands and goods as freedmen. In a few rare instances liability to servile duties and payments in respect of lands seemed to have continued down to the reign of Charles I. In Scotland serfdom died out earlier than in any other country in Europe, being virtually extinct at the end of the 14th century, but in the 17th century a remarkable form of it was revived. Colliers and salters were bound by the law, independent of paction on entering to a coal-work or salt-mine, to perpetual service there; and in case of sale or alienation of the ground on which the works were situated, the right to their services passed without any express grant to the purchaser. The sons of the collier and salter could follow no occupation but that of their father, and were not at liberty to seek for employment anywhere else than in the mines to which they had been attached by birth. Statutes 15 Geo. III. chap. 28 and 39 Geo. III. chap. 56 restored these classes of workmen to the rights of freemen and citizens, and abolished the last remnant of slavery in the British Islands.

In France, though a general edict of Louis X. in 1315 purported to enfranchise the serfs on the royal domain on payment of a composition, this measure seems never to have been carried into effect, and a limited sort of villeinage continued to exist in some places down to the Revolution. In Italy one great cause of the decline of villeinage was the necessity under which the cities and petty states found themselves of employing the peasant population for their defence, whom it became expedient to reward with enfranchisement. In the 11th and 12th centuries the number of serfs began to decrease, and villeinage seems no longer to have had an existence in Italy in the 15th century. Joseph II. abolished serfdom in Bohemia and Moravia in 1781, and in the German lands in 1782. Over a large portion of Germany the mass of the peasants had acquired

their freedom before the end of the 13th century, but in some parts of the Prussian dominions a modified villeinage (*Leibeigenschaft*) continued to exist until swept away by the reforms of Von Stein in the 19th century. In Russia (q.v.) serfdom remained a part of the social system until 1861.

Negro Slavery existed from the earliest times; the Carthaginians seem to have brought caravans of slaves from various parts of North Africa; but in this the negroes suffered no more than other contemporary barbarians. The negro slavery of modern times was a sequel to the discovery of America. Prior, however, to that event the negroes, like other savage races, enslaved those captives in war whom they did not put to death, and a considerable trade in slaves from the coast of Guinea was carried on by the Arabs. The deportation of the Africans to the plantations and mines of the New World doubtless raised the value of the captive negro, and made slavery rather than death his common fate; while it may also have tempted the petty princes to make war on each other for the purpose of acquiring captives and selling them. The aborigines of America having proved too weak for the work required of them, the Portuguese, who possessed a large part of the African coast, began the importation of negroes, in which they were followed by the other colonisers of the New World. The first part of the New World in which negroes were extensively used was Hayti in St Domingo. The aboriginal population had at first been employed in the mines; but this sort of labour was found so fatal to their constitutions that Las Casas (q.v.), Bishop of Chiapa, the celebrated protector of the Indians, interceded with Charles for the substitution of African slaves as a stronger race. As early as the beginning of the 16th century a good many Africans were already in Hispaniola; the emperor accordingly in 1517 authorised a large importation of negroes from the establishments of the Portuguese on the coast of Guinea. Sir John Hawkins (q.v.) praying for help to the Almighty God (who never suffered his elect to perish), was the first Englishman who engaged in the traffic, in which his countrymen soon largely participated, England having exported no fewer than 300,000 slaves from Africa between the years 1680 and 1700; and between 1700 and 1786 imported 610,000 into Jamaica alone. At first the trade was in the hands of special companies, one of which long enjoyed the special right or *Asiento* (q.v.) from Spain of supplying slaves. Most of the English slaving ships belonged first to Bristol, and from 1730 onwards to Liverpool (q.v.). The slave-trade was attended with extreme inhumanity; the ships which transported the negroes from Africa to America were overcrowded to such an extent that a large proportion died in the passage; and the treatment of the slave after his arrival in the New World depended much on the character of his master. Legal restraints were, however, imposed in the various European settlements to protect the slaves from injury; in the British colonies courts were instituted to hear their complaints; their condition was to a certain extent ameliorated, and the flogging of women was prohibited. But while slavery was thus legalised in the British colonies, it was at the same time the law of England (as decided in 1772 by Lord Mansfield in the case of the negro Somerset, and less emphatically by other judges at earlier dates, without any actual statute on the subject) that as soon as a slave set his foot on English soil he became free; though, if he returned to his master's country, he could be reclaimed. Up till this date the contrary impression was the usual one, though public opinion was strongly setting against the custom of keeping slaves. In 1764 there were believed to be

thousands of negro slaves in London; and advertisements of 'black boys' for sale were frequent, as also rewards offered for runaways. As late as November 1771 the *Birmingham Gazette* advertised the public sale of a negro boy, sound, healthy, and of a mild disposition. Even for the British, however, personal liberty was often an illusion rather than a reality. The press-gang seized men for ships of war, and kidnappers impressed them for service in the East India Company or in the American colonies.

Before the idea of emancipation was contemplated the efforts of the more humane portion of the public were directed towards the abolition of the traffic in slaves, mainly under the influence of a sense of Christian duty. In 1787 a society for the suppression of the slave-trade was formed in London, numbering Thomas Clarkson and Granville Sharp among its original members. The most active parliamentary leader in the cause was William Wilberforce, and Zachary Macaulay was one of its most zealous friends. The Quakers were the only religious body who as such petitioned the House of Commons on the subject. Many people, such as the Rev. Raymond Harris, a Jesuit from Liverpool, defended slavery. W. Penn, though he did much to improve the condition of negro slaves, was himself a slave-owner. Boswell, who on this point opposed his master, speaking of 'so very important and necessary a branch of commercial interest,' says: 'To abolish a status which in all ages God has sanctioned and man has continued would not only be robbery to an innumerable class of our fellow-subjects, but it would be extreme cruelty to the African savages, a portion of whom it saves from massacre and introduces to a much happier life' (*Life of Johnson*, chap. xxxv.). Lord Nelson declared he would always be ready to oppose the 'damnable, cruel doctrine of Wilberforce and his hypocritical allies.' In 1788 an order of the crown directed that an inquiry should be made by a committee of the Privy-council into the state of the slave-trade; and an act was passed to regulate the burden of slave-ships and otherwise diminish the horrors of the middle passage. A bill introduced by Wilberforce for putting an end to the further importation of slaves was lost in 1791, but in 1792 Wilberforce, supported by Pitt, carried a motion to abolish the slave-trade gradually. And it is noteworthy that the anti-Christian French convention, influenced by the teaching of Rousseau, decreed (4th February 1794) that slavery should be abolished throughout the French colonies, and all slaves admitted to the rights of French citizens. Meanwhile, conquest of the Dutch colonies having led to a great increase in the British slave-trade, an order in council in 1805 prohibited that traffic in the conquered colonies; and in the following year an act was passed forbidding British subjects to take part in it, either for the supply of the conquered colonies or of foreign possessions. In the same year a resolution moved by Fox for a total abolition next session was carried in the Commons, and, on Lord Granville's motion, adopted in the Lords; and the following year the general abolition bill, making all slave-trade illegal after 1st January 1808, was introduced by Lord Howick (afterwards Earl Grey) in the House of Commons, was carried in both Houses, and received the royal assent on 25th March 1807. British subjects, however, continued to carry on the trade under cover of the Spanish and Portuguese flags; the slave-ships were more crowded than ever, to reduce the chances of capture, and the negroes were not unfrequently thrown overboard on a pursuit. The pecuniary penalties of the act were discovered to be inadequate to put down a traffic so lucrative as to cover all losses by capture.

Brougham therefore in 1811 introduced a bill, which was carried unanimously, making the slave-trade felony punishable with fourteen years' transportation, or from three to five years' imprisonment with hard labour. An Act of 1824 declared it piracy, and, as such, a capital crime, if committed within the Admiralty jurisdiction; and the statute of 1837, mitigating the criminal code, left it punishable with transportation for life. The Anti-slavery Society practically established the colony of Sierra Leone in 1787 as a home for destitute negroes.

The United States of America abolished the slave-trade immediately after Great Britain (1808), and the same was in the course of time done by the South American republics of Venezuela, Chile, and Buenos Aires, by Sweden, Denmark, Holland, and, during the Hundred Days after Napoleon's return from Elba, by France. Great Britain, at the peace, exerted her influence to induce other foreign powers to adopt a similar policy; and eventually nearly all the states of Europe passed laws or entered into treaties prohibiting the traffic. The accession of Portugal and Spain to the principle of abolition was obtained by treaties of date 1815 and 1817; and by a convention concluded with Brazil in 1826 it was declared piratical for the subjects of that country to be engaged in the slave-trade after 1830. By the conventions with France of 1831 and 1833, to which nearly all the maritime powers of Europe have since acceded, a mutual right of search was stipulated within certain seas, for the purpose of suppressing this traffic. The provisions of these treaties were further extended in 1841 by the Quintuple Treaty between the five great European powers, subsequently ratified by all of them except France. The Ashburton treaty of 1842 with the United States provided for the maintenance by each country of a squadron on the African coast; and in 1845 a joint co-operation of the naval forces of England and France was substituted for the mutual right of search.

The limitation of the supply of negroes naturally led, among other good results, to a greater attention on the part of the masters to the condition of their slaves. But the attention of British philanthropists was next directed towards doing away with slavery altogether in the colonies. Societies were formed with this end, an agitation was set on foot, and attempts were made, for some time without success, to press the subject of emancipation on the House of Commons. At length in 1833 a ministerial proposition for emancipation was introduced by Mr Stanley (Earl of Derby), then Colonial Secretary, and an emancipation bill passed both Houses, and obtained the royal assent 28th August 1833. This act, while it gave freedom to the slaves throughout all the British colonies, at the same time awarded an indemnification to the slave-owners of £20,000,000 under cover of a loan, repayment of which was never demanded. Slavery was to cease on 1st August 1834; but the slaves were for a certain duration of time to be apprenticed labourers to their former owners. Objections being raised to the apprenticeship, its duration was shortened, and the complete enfranchisement took place in 1838. The serious decadence of trade and commerce in the British West Indies has been commonly attributed to emancipation; but though the change in the position of the negroes unquestionably contributed to the result, it is clear that before a slave had been manumitted by law the industry of Jamaica and the other islands had already begun to fall off. It must be remembered that though slavery is abolished in the British empire, that is true only of the empire in a restricted sense. Slavery still exists in British protectorates in Africa and in Indian states. In these, however, emancipation progresses.

The French emancipated their negroes in 1848; as did most of the new republics of South America at the time of their establishment; while the Dutch slaves had freedom conferred on them in 1863. In Hayti slavery ceased as far back as 1791, its abolition having been one of the results of the negro insurrection of that year. In Brazil (q.v.) slavery was not abolished until 1888.

The history of negro slavery in the United States is partly dealt with at Negroes (q.v.); the steps that hindered or prepared the way for its final abolition in 1862-65 are part of the history of the United States (q.v.), and are dealt with in such articles as ABOLITIONISTS, BROWN (JOHN), DRED SCOTT CASE, FUGITIVE SLAVE LAW, GARRISON, LINCOLN, MISSOURI (for the 'Missouri Compromise'), &c. Here it may be noted that in 1800 there were in the United States 893,041 slaves; that Vermont, Pennsylvania, Massachusetts, Rhode Island, Connecticut, New York, and New Jersey emancipated their slaves before 1840, most of them by gradual measures. The average value of slaves was about this period stated at \$600. The 3,953,760 slaves at the census of 1860 were in what were known as the Southern States. Eminent leaders of public opinion from the earliest period of the national existence—such as Washington, Franklin, Jefferson, Madison, Jay, Hamilton—regarded slavery as a great evil, and inconsistent with the principles of the Declaration of Independence. The Society of Friends uniformly opposed slavery, and agitated against it. The Presbyterian Church made six formal declarations against it between 1787 and 1836. The Methodist Episcopal Church always cherished strong anti-slavery views; though when in 1844 one of their bishops was suspended for refusing to emancipate slaves he had inherited through his wife, a secession took place, and the Southern Methodist Episcopal Church was formed. Individuals and groups of persons of almost all churches were found defending slavery. In 1835 the Charleston Baptist Association resolved that the right of masters to dispose of their slaves had been distinctly recognised by the Creator. In 1836 a North Carolina bishop strongly commended for publication a sermon which declared that without a new revelation from heaven no man was authorised to pronounce slavery wrong. In 1838 the New School Presbyterian Church in Petersburg, Virginia, protested against a resolution of the General Assembly declaring slavery a sin against God, pronounced that resolution irreconcilable with American civil institutions, and affirmed that the relation of master and slave had been recognised by the great Head of the Church. Yet, on the whole, anti-slavery views grew steadily; but until the crisis of the civil war very many of those who personally held strong anti-slavery opinions hesitated to join actively in abolitionist agitation, as unwilling to invade what many of their fellow-citizens held to be their indisputable rights. To this halting attitude the war put an end.

Mohammedanism (q.v.) recognises the institution; Mohammed's own precepts insist on the kindly usage of the slave; and Moslem slavery is mainly domestic slavery, household slaves being on the whole well treated. But there is no more awful chapter in the history of human callousness and human misery than the story of the slave-trade as carried on by 'Arab' or Moslem slave-traders, its main tracks from the interior of Africa to the coast being in many places marked by the whitened bones of slaves who during the ages sank in the way, fell out of the caravans in spite of the lash, and died or were slaughtered to save trouble. The main regions from which slaves were procured for the Moslem East were the Sudan

proper, the Egyptian Sudan, or Valley of the Upper Nile, Somali Land, and the borders of the Portuguese East African territory. British and other men-of-war have long been employed in capturing slave-dhows on the east coast. In 1869 the Egyptian Khedive Ismail gave Sir Samuel Baker large powers for the suppression of the slave-trade, a crusade carried on by Gordon Pasha. The sultan of Zanzibar signed a treaty for the suppression of the trade in 1873. By occupying Caucasasia, Russia stopped an important supply for the Turkish harems; it also closed the slave-markets of Khiva and Bokhara, and by crushing the Turkomans (Tekkes and others) freed at once 40,000 slaves. Cardinal Lavigerie, who became archbishop of Algiers in 1867, made the suppression of the slave-trade and slavery his life work, and secured the help of many zealous fellow-workers. The Congo Free State under Leopold II. disappointed the hopes of its founders, and many of the atrocities associated with it only came to an end with the accession of King Albert (1909), while forcible recruitment of labourers in Central Africa for the St Thomas cocoa plantations was also stopped in the same year. Slavery, implying native labour procured by force or fraud and applied for private profit, has continued into the 20th century in two forms: first, by slave-raiding and business-trafficking in slaves, raids from Abyssinia into Kenya and the Sudan being especially notorious; second, by transfer, gift, inheritance, adoption, debt-bondage. The demand for tropical products (cotton, rubber, sugar, copra, ivory, palm-oil, &c.) involves a demand for cheap labour, together with the tendency to exploit that labour. The problem in many of the British African colonies or protectorates (especially in those on the east, such as Kenya) of obtaining labour fairly and effectively is already serious, as many colonists sink their capital in the country on the assumption that labour is both cheap and plentiful, and wholesale 'removing' of tribes is not a policy to be commended. The League of Nations (q.v.) has done much useful work towards the abolition of slavery, by various conventions (together with related conventions such as those on the illicit trade in arms), of which the most important was that which, under the guidance of Lord Cecil, passed the assembly of the League in 1926. Just previously, the Maharaja of Nepal had liberated over 50,000 slaves in his kingdom, but it was estimated that there were then in the world still some 3,000,000 slaves, of whom about 2,000,000 were to be found in Abyssinia, while the slave-trade was actively practised in various parts of the Sahara, in Liberia, China, in several Mohammedan states in Asia, and in particular in the Arabian peninsula, especially the Hejaz. While labour conditions in the Congo have enormously improved, it would appear that they are still very unsatisfactory in Portuguese Angola and Mozambique, and in other parts of Africa.

Slavonia. See CROATIA, SERBIA.

Slavs, or SLAVONIANS (native name, *Slovane* or *Slovane*, probably connected with *slovo*, 'a word,' thus meaning the people who spoke intelligibly as distinguished from their neighbour, *Niemets*, the German, literally the 'dumb man'; this opinion is held by the majority of scholars, but lacks the support of Miklosich, who considers both to be tribal names), the general appellation of a group of nations belonging to the Indo-Germanic family, whose settlements extended from the Elbe to Kamchatka, from the Frozen Sea to Salonika, the whole of eastern Europe being occupied almost exclusively by them. They were settled in this continent before historical times, as their migrations are never mentioned. It seems probable from the description given in the fourth book of Herodotus that at least one of the Scythian tribes, the Budini, was Slavonic, and to it may perhaps be added that of the Nemi. The original names of the Slavonic tribes seem to have been Wini or Wends (*Venedi*) and Serbs. The former of these names occurs among the Roman writers, and later, in Jordanis, in connection with the commercial peoples of the Baltic; the latter is spoken of by Procopius as the ancient name common to the whole Slavonic stock. The earliest historical notices represent the Slavs as having their chief settlements about the Carpathians, from which they spread northward to the Baltic, westward as far as the Elbe and the Saal, and later, after the overthrow of the kingdom of the Huns, southward beyond the Danube, and over the whole peninsula between the Adriatic and the Black Sea. These migrations ceased in the 7th century; the division of the Slavonic stock into separate branches became now more complete, and gradually they began to form independent states. The sections of the stock may be divided into three groups; the western includes the Poles, Wends, Czechs, and Slovaks (the two latter frequently classed together as Bohemians), estimated at about 29½ million; the southern the Serbo-Croatians, Bulgarians, and Slovenes, estimated at 15½ million; the eastern the Great Russians, Little Russians (Ukrainians), and White Russians, estimated at 103 million. This makes a total of the Slavonic populations of 148,000,000, but in many cases accurate figures are not easily available. Many of the old Slavonic states lost their independence and were till the 20th century in a state of greater or less vassalage. Russia, Serbia, and Montenegro alone were wholly independent. Bulgaria was till 1908 a tributary state of Turkey, but practically independent. Till 1918 Bohemia and Moravia were united to Austria, and outside of Serbia and Montenegro there were southern Slavs (Yugo-slavs) subject to Austria,

to Hungary, or to both jointly. Poland was distributed between Russia, Austria, and Prussia. Some Slavonic tribes had never enjoyed independence—e.g. the Sorbs and Slovenes. The Slavism of the 19th century turned out to be an illusion and a dream.

The Slavs are represented by ancient writers as an industrious race, living by agriculture and the rearing of flocks and herds; as hospitable and peaceful, and making war only in defence. The government had a patriarchal basis, and chiefs were chosen by the assemblies. But in the west contact with the feudal institutions of the German empire, and in the east with Byzantium and the Mongols, greatly altered this primitive constitution; the Slavonic princes aimed at unlimited power, and the chiefs succeeded in binding the free peasants to the soil, as the feudal nobility had done. In the course of the 11th, 12th, and 13th centuries a hereditary monarchy was formed in some of the Slavonic states. The people sank into the lowest condition of serfdom. Between them and the nobles there was no third or middle class, as the privileges of the nobility prevented the growth of towns, and such trade as there was was chiefly in the hands of foreigners.

The religion of the ancient Slavs, like that of the Teutonic nations, seems to have been in many of its features a kind of nature-worship—not without, perhaps, a predominating divinity: at least so Procopius tells us. But the whole subject of Slavonic mythology is in a very confused state. For our information about Slavonic deities we are indebted to Nestor and the German chroniclers who wrote about the Baltic Slavs—e.g. Thietmar, Helmold, and others. We thus only know the gods of these peoples and the Russians. About those of the Poles, Czechs, and southern Slavs we know very little. The idols, from the accounts given of them, appear to have been of wood; and this is probably the reason why no genuine remains of them have come down to us. The chief deity, whose worship was probably common to all the western Slavs, was Sviatovit, with whom may be associated Perun and Radegast—and some have thought that these three names denote different personations or manifestations of the same power. Of gods of an inferior order we may name Prowe, perhaps a god of justice, and Chernobog, the black god, together with multitudes of demons and spirits good and bad. Thus, among the Russians there were *rusalki*, water-nymphs, *leshie*, satyrs; and among the Serbs and Bulgarians, *velas* and *samo-divas*, a kind of malicious fairy.

Some of these deities were worshipped under monstrous forms: thus, Sviatovit had four heads, Rugewit, the god of war, had seven faces, and so on. The Slavs seem to have had some crude notion of existence and retribution after death. Worship was performed in groves and temples, cattle and fruits being offered by the priests, whose office was originally performed by the head of the family or chieftain; perhaps this may be the reason why there is a common name for priest and prince (*knez*) among the western Slavs: the word, however, is certainly borrowed from the O. H. Ger. *chuning*. The eastern Slavs received Christianity from Byzantium in the 9th century, through the instrumentality of Cyril (q.v.) and Methodius; the western from Rome and Germany. They were christianised with little opposition, for they had no religious caste, and there were no persons politically or socially interested in the cultus of their idols.

SLAVONIC LANGUAGES.—The term Slavonic, is a generic name (like Celtic or Teutonic) for a group of kindred languages and people belonging to the great Indo-European family. The Slavonic

languages are in a highly inflected state: the noun has seven cases, and all the numerals are declined. An article is implied in the termination of the adjective, as is shown by the form which it assumes when used as a predicate. As regards tenses, Russian, Polish, and Czech in their modern forms have lost the imperfect and aorist, but they are preserved in Serbo-Croatian and Bulgarian. The poverty of the tense-system is amply compensated by the so-called *aspects*, which are found in every Slavonic verb—e.g. the frequentative, the momentaneous, and others, which supply tenses that may be wanting to the simple verb and express very delicate distinctions of time and manner. The Slavonic family in preserving these aspects has been truer to the old type of language than Teutonic. Traces of them can be seen in Greek and in Old Irish. The prepositions in and out of composition are used with a delicacy reminding us of ancient Greek. These languages have great power of compounding words, and rich vocabularies. The oldest form known is the Paleo-Slavonic or ecclesiastical Slavonic, so called because used in the Orthodox churches. The original home of this language has been the subject of much dispute, and has divided Slavists into two camps; some finding it in Bulgaria, others in the ancient Pannonia, now corresponding to the territory occupied by the Slovenes; hence it is sometimes called Old Bulgarian and sometimes Old Slovenish. It is, however, only an elder sister and not a mother language. The Slavonic family of languages can be divided into groups. The western—Polish (including Kashubish), Czech, Slovak, and Wendic (or Sorbic, divided into two varying dialects); the southern—Serbo-Croatian, Slovenish, and old and modern Bulgarian, the latter having lost nearly all its cases and the infinitive mood; the eastern—Russian, Ukrainian, and White Russian, the latter treated as a distinct language by Miklosich. Polish, which died out at the beginning of the 18th century, has been preserved in some vocabularies, &c.: from these fragments Schleicher constructed a grammar. Polish, Czech, Croatian, and Wendic are written in the Latin alphabet, and the remainder in the Cyrillic. See the sections on language and literature in the articles BULGARIA, CZECHO-SLOVAKIA, POLAND, RUSSIA, and SERBIA. We may here remark that in literature Russian, Polish, and Czech are richest, the two latter nations having developed a literature much earlier than the former. This remark applies especially to Czech, which can show good prose-writing in the 14th century. Many of the Russian and Polish poets have very great merit. Slovenish and Sorbish are poor. The Serbs developed a respectable literature in the 19th century, and the Bulgarians are already active. But both have only recently shaken off the Turkish yoke, fatal to all progress. Serbian, Russian, and Bulgarian are very rich in old ballads and popular songs. These are scanty in Czech, and almost entirely wanting in Polish. Old Bulgarian literature, as it has come down to us, consists mainly of religious works, original and translated.

See books on the Slavs by Mickiewicz (in Fr., 1849), Léger (in Fr., 1873, 1890–99), Korczak-Branicki (in Fr., 1879), Einfeldt (in Ger., 1907), Balch (in Eng., 1910), Niederle (in Fr., 1911), Radosavljevič (Eng., trans. 1919) and Rivet (in Fr., 1919–20); Bibliography by Kerner (1918); books on Pan-Slavism by Krasinski (1848) and Nötzel (1914), both in Ger.; various books on the Slavonic Churches by Jagić (in Ger., 1913, 1916, 1919–20); histories of Slavonic Literature by Safarik (1869), Fyppin and Spasović (1880–84), and Murko (1908); all in Ger.; studies of the Literature by Talvi (Mrs Robinson, 1850), Morfill (1883), and Popović (1917), all in Eng.; Anthologies in Ger. by Berneker (1903), and in Eng. by Selvor (1919); various works on Slavonic languages by Miklosich, including his Grammar (1868–79) and his Dictionary

(1886), and books by Jagić (1908), and Block (1911), all in Ger. See also the articles on the various Slav peoples and countries, and the books there cited.

Sleaford, a town of Lincolnshire, on the right bank of the Slen, a branch of the Witham, 17 miles SSE. of Lincoln. It has a fine church (12th to 15th century), a grammar-school (1624), and a monumental cross (1850). Here King John fell sick after crossing the Wash, and whilst spending the night in the old castle (now almost wholly disappeared). Pop. 6680.

Sledges, or **SLEIGHS**, are travelling vehicles without wheels, which in some form are in use in all countries where snow lies for any considerable part of the year. Usually they are on runners—either one or two pairs—which are connected by a framework and support the body of the vehicle; but the well-known travelling-sledge (*pullha*) of the Laplanders, built in the form of a canoe, with sharp bow and square stern, of light materials and covered with reindeer skin, has no runners. In the northern United States and in Canada, where sleighs are brought to great perfection, lightness, and beauty, they take the place of carriages in winter; and there, too, sleds of lighter build, and supporting a light platform or seat, are made for coasting—i.e. sliding down hills. Long sleds for this purpose, sometimes capable of carrying forty persons, have two pairs of runners with their framework, on which a platform rests (often like a ladder, covered with a cushion); the front pair of runners is turned on a pivot by a steersman with the aid of ropes and pulleys. In Canada toboggans are in popular use for coasting (here called *tobogganing*), and consist of a single length of wood (or two boards joined together), about $\frac{1}{2}$ inch thick, curved backward in front, and the curved portion held back by leather thongs. The toboggan, of course, has no runners, may accommodate two to eight persons, and is guided by the steersman's foot dragging behind, toe downward. In Russia sledges are often drawn by a team of three horses (*troika*).

Sleep is symptomatic of repose in the brain and nervous system; in those who are awake cerebral activity is unceasing. Potential energy is being constantly expended in mental operations, vital processes, muscular movements, &c.; also in the perception of impressions that stream towards the brain incessantly from every part of the economy and of the environment. This is attended by wear and tear of the nervous textures, and by the deposition in them of waste-products proportionate to the work effected. Waking is therefore a positive condition—one in which energy is consumed more quickly than it is restored, and than the waste-products are eliminated. It is a state that entails a full working blood-supply to the brain. After a time, longer or shorter, a sense of fatigue suggestive of repose supervenes that is only relieved by sleep. Sleep, on the contrary, is a negative state—one in which these processes are reversed. The brain is inactive; consciousness and volition are in abeyance; coincidentally the central blood-supply is diminished, the brain is smaller in size, and its temperature is lowered. Expenditure of energy is curtailed to the greatest extent compatible with life. Recuperative processes continue, and predominate over the destructive; the nervous structures are depurated, and potential energy is accumulated. When recuperation is completed awaking occurs, and is accompanied by feelings of invigoration. Waking and sleep, therefore, are indicative of cerebral activity and of cerebral rest; they are both physiological functions of a healthy nervous system. When either is unduly prolonged, curtailed, or

modified it gives evidence of a departure from health.

The brain is a composite organ. It contains innumerable centres which dominate an equally vast variety and number of functions; and these require and obtain sleep in varying degrees according to their functions. The supreme (psychical) centres which are constantly alert during waking need more sleep than some of the subordinate centres. These latter rest partially by day, so that the complete abdication of their functions at night is less urgently required.

The incursion of sleep is gradual. It is synchronous with the subsidence of activity in the brain and nervous system, and it is best studied in this connection. Molecular activity does not cease in the whole brain instantly, but in one portion after another until the whole organ becomes tranquil. It is suspended first in the centres situated highest in the cerebrum, and afterwards in those at lower levels, till the medulla oblongata and spinal cord are included. It consequently affects the motor centres of the brain first. The earliest symptom of sleep is the weakening of the voluntary muscles; relaxation takes place in one set after another until the body assumes the horizontal posture. The sphincter muscles are exceptional; they remain contracted. During deep sleep true slackening occurs in the muscular fibres, even in diseases like tetanus and hydrophobia. A man may fall asleep in motion, as in walking or riding, and maintain his equilibrium; a certain amount of activity being sustained in the motor centres enables him to do so. If he yields to sleep in a stationary attitude, the motor centres being quiescent, he tends to sink into the recumbent posture. Activity next wanes in the psychical centres of the brain. The will ceases to control the working of the intellectual faculties, and the perceptive powers are lessened. The mind, no longer inhibited from within nor corrected from without, revels in absurdities until mental operations cease, or, at least, till they are wrapped in oblivion. The centres of the special senses in the brain are next involved, and usually in the following order; they fail to perceive slight or ordinary impressions, while their special nerves transmit them in a slow and imperfect manner. (a) Vision: The eyelids close; the eyeballs turn upwards and inwards in the orbits. The eyeballs occasionally, if rarely, move independently, and not in unison, during sleep. The pupils contract—the contraction being in ratio to the depth of sleep; they dilate widely in the act of awaking. (b) Hearing: Loud noises interrupt sleep, though an expected noise does so more readily. Monotonous sounds do not prevent or interrupt sleep; their cessation may terminate it. (c) Smell: Slight odours may prevent the onset of sleep; but very pronounced smells are required to disturb it. (d) Taste: It is difficult to determine the condition of this sense during sleep, the sense of touch being apt to vitiate the conclusion. (e) Touch: This is the most sensitive sense during sleep. It is chiefly through it that man is warned of danger, and that his safety is secured. Reflex acts can always be elicited, their vigour depending on the strength of the stimulus, the degree of sensitiveness of the part to which it is applied, and the depth of sleep. The centres in the medulla oblongata then become less active. They chiefly dominate the heart, the lungs, and arterial pressure. The heart beats from ten to twenty times less per minute, and the blood pressure is diminished. The respirations are about four fewer per minute. The inspirations are shallower and chiefly thoracic. The pause between inspiration and expiration is practically absent.

Pettenkofer and Voit stated that of the total carbonic acid eliminated in twenty-four hours 58 per cent. is given off during the twelve hours of day and 42 per cent. during the twelve hours of night; whilst 67 per cent. of the oxygen taken in is absorbed during the twelve hours of night and 33 per cent. during the day. The centres that dominate the various secretions only respond to suitable stimuli, and as these are wanting during sleep the secretory organs are less active. The digestive juices are not formed, and if the gastro-intestinal movements do not cease entirely, they are greatly lessened. The urine is secreted in one-fourth the quantity. The quantity of sodium chloride, sulphates, and urea it contains is smaller; the latter is decreased one-half. The secretion of sweat is increased, and that of milk is continued.

In consequence mainly of the inactivity of the bodily functions the bodily temperature falls as much as from $0^{\circ}5$ to 2° F., chiefly for some hours after midnight; it being lowest about 4 A.M. It falls similarly by day in those who work by night and sleep by day. According to Helmholtz, a man gives off about three times more heat when he is awake than he does when he is asleep. During sleep the economy is more vulnerable to the influence of deleterious surroundings; it has less resisting power. Hence it is that poisoning by gas and the effects of extreme cold, such as frost-bite, are most readily contracted during sleep; hence also the liability to catch cold from sleeping in a draught. Briefly summarised, during sleep the brain, ganglia, medulla oblongata, and spinal cord are in a state of repose. And the extent to which they are involved may be inferred from the fact that sleeping persons suffer little, if any, from shock in accidents which affect those who are awake most injuriously.

Sleep varies in depth in persons of different ages. It is usually profound in the young, and light in the aged. The depth bears some relation to its duration. Natural sleep varies from time to time during the same night. The observations of Kohlschütter, of Rummo and Ferrannini, and of Mönninghoff and Piesbergen showed that it was deepest an hour after its onset, when its intensity decreases quickly, then more slowly, and again it becomes more profound a second time after four to five hours. This is important in sleep-disturbance, for excitations will act more powerfully when it is lightest. On the other hand, when it is deepest the lowest centres are least inhibited, and the blood is less thoroughly oxygenated. It is then that epileptic, convulsive, spasmodic, and such-like seizures are most apt to occur. Cases of sleep lasting for weeks and months have been recorded (that of Johann Latus in the hospital of Myslowitz in Silesia in 1891-92 lasted 4½ months); in Britain it occurs in neurotic patients, and sometimes is called trance. It is pathological and not natural sleep. In western Africa 'sleeping sickness' is a well-known fatal disease.

Cause of Sleep.—For upwards of two thousand years continuous attempts have been made to elucidate the cause of sleep without success; many theories have been promulgated, but they have fallen short of explaining it.

Of *circulatory theories* the one that prevailed during many centuries attributed sleep to a determination of blood to the head; and much evidence was adduced in its support. Nevertheless, congestion of the brain is incompatible in health with good and refreshing sleep. This hypothesis was replaced by the anæmic theory. From the observations of Donders (1854), Durham (1860), Regnard (1868), Hammond and Weir-Mitchell (1869), and Ehrmann, Salathé, and F. Franck (1877), it would seem to be conclusively demonstrated that

the blood-supply of the brain is lessened during sleep. Whether this is causative, concomitant, or consequent is still open to conjecture. Pathological anemia is a well-recognised source of wakefulness. It appears certain that a blood-supply sufficient for nutritive purposes, but insufficient for mental activity, is an essential factor in natural sleep. The brain, like all other organs, governs and is not governed by its vascular supply.

Humboldt suggested one of several *chemical theories*—that sleep was due to the want of oxygen; and many have since urged that everything that deprives the brain of oxygen conduces to sleep. An atmosphere deficient in oxygen, or one containing an excess of carbonic acid, induces drowsiness and sleep, but it is poisoned, and not healthy sleep. Pfleger believed that activity of the psychical cells depends on the quantity of intra-molecular oxygen they contain, and that all function is attended (particularly in the gray matter) by explosive movement in the cells, caused by the combination of oxygen with the tissue-elements, in which oxygen is consumed and carbonic acid is formed. He thought that these movements used up the oxygen at a greater speed than the circulation could replace, and that a time arrived when the lack of oxygen and an excess of carbonic acid caused drowsiness and sleep. Again, it has been urged that the waste-products (resulting from mental operations) in the nervous textures occasioned sleep. Preyer believed that the accumulation of these (ponogenes) at first caused fatigue, then sleep, and that waking occurred when they were eliminated in sleep. This doubtless is a factor in the causation of sleep, but it does not explain it.

The absence of external stimuli, such as occurs in the darkness and quietness of night, has been credited with causing sleep. It is a desirable aid to sleep, but, in health, sleep ensues despite all disturbing agencies—even on the torture-rack. Sleep has been ascribed to the law of periodicity that governs all organised things. The study of the bodily functions shows that rest and activity alternate—even the heart gets about ten to twelve hours rest in the pauses between its contractions. Of other numerous theories, it will suffice to say that no one of them can be accepted as fully explaining and finally settling the subtle problem. It may be that the mystery will never be solved until a deeper insight into the working of the mind itself is acquired.

How long should one sleep? is a question that must be answered generally. No hard and fast law can be laid down; every man must be a rule to himself. It is quite clear that nature intends everyone to sleep until the effects of waking are dissipated, and until the bodily energy is renovated. In childhood, when the constructive processes of growth involve large expenditure of energy, sleep is long and profound. In youth much sleep is still needed. In middle age, when decay and repair alone require to be balanced, less sleep is required. In old age, when repair is slowly and imperfectly effected, more sleep is desirable. The duration of sleep is also largely influenced by sex, temperament, occupation, habit of sleep, season, climate, &c. The true guide is the recuperation of the energies; that is indicated by a feeling of well-being on awakening. Some persons awake, after sleeping for an apparently sufficient number of hours, worn, jaded, and exhausted. That is an indication of disease, pointing to an inability on the part of their textures to accomplish their reparation.

Sleeplessness.—The effects of curtailed sleep are very marked. The loss of a single night's sleep is attended by symptoms of enervation; that of several

nights' sleep, by serious consequences. In many diseases the lack of sleep determines a fatal issue; conversely, sleep often determines recovery. Few persons appreciate the fact that the voluntary curtailment of sleep for an hour every night for a year is equivalent to the loss of forty-four nights' sleep of eight hours' duration. That represents an enormous expenditure of energy—e.g. during that time the cardiac pulsations are approximately 210,000 and the respirations about 90,000 more frequent than they would have been during sleep. Undue curtailment of sleep is attended by loss of flesh, the essence of emaciation being the preponderance of decay over repair. The skin becomes dry, and it loses its suppleness and translucency. All the bodily textures are badly nourished, and the organs suffer from lack of innervation. When sleep has been limited unduly, inability to sleep ensues and becomes the bane of existence. Exhaustion of the cerebral structures leads to still graver symptoms, such as insanity. Indeed, insomnia preludes or enters to a greater or less extent into the causation of almost every form of mental alienation. They arise from similar causes. Many of the tragedies of life are due solely to the prolonged want of sleep. Insomnia or continued sleeplessness may cause death from exhaustion. Sleep, on the other hand, is a powerful curative agent—one that alone suffices to determine recovery. It has been well called 'the chiefest thing in physic.'

Sleeplessness is a symptom designed to subserve a highly conservative purpose. It attracts attention in some to ailments that might otherwise elude detection; in others it maintains consciousness requisite for the preservation of life. Sleeplessness is symptomatic of cerebral activity. This may be originated and perpetuated in divers ways. It may arise from mental causes, for the mind is dependent on the brain for its external manifestation. In mental overwork, worry, grief, suspense, &c. the intellectual or emotional centres respectively grow hyperæmic. At night the vaso-motor nerves that dominate the arterial vessels, worn out by continued inhibition, fail to moderate the supply of blood to these centres, and so the man is impelled to work and to worry, and he is prevented from sleeping. In the early stages he is long in falling asleep, and when he does it is to dream of his work and worry. Eventually insomnia becomes pronounced. Sleeplessness may depend on faulty conditions in the brain itself. Cerebral cells primarily or congenitally feeble, or secondarily debilitated by unhealthy conditions, display their enfeeblement in an incompetency to accumulate nervous force. Their molecules are rearranged in a preternaturally unstable manner, and they discharge their latent energy in response to trifling excitations. Such cells are designated 'explosive.' The peripheral cells generally participate in the enfeeblement, and they and their conducting nerves transmit impressions in a rapid and exaggerated manner. The reaction-time is lessened. This is a fruitful source of wakefulness in neurasthenia and its allied conditions. Sleeplessness from this cause usually appears at the epochs of life, and under privations or strains. The patient gets to sleep easily, but awakes in two or three hours, to remain awake till five or six in the morning. The awaking is often attended by distress and misery. It is in this class of cases that insomnia often occurs and recurs mysteriously. All neurotic diseases tend to recur paroxysmally; a bad sleep-habit once acquired is liable to return from time to time from very trivial causes.

Sleeplessness may result from a blood-supply altered either as regards quantity or quality. The cerebral cells are very sensitive to their environ-

ment; they bear excess and deprivation badly. Hyperemia and anæmia of the brain are consequently productive of cerebral unrest and of wakefulness; and these brain-conditions may arise from diseases of the heart, lungs, and other organs, which secondarily implicate the cerebral circulation. The brain textures are unfavourably affected by alterations of vascular tension; high tension is unfavourable to sleep. They are equally disturbed by overheated blood such as pertains to feverish states. They are similarly perturbed by blood contaminated by peccant matters, such as those of gout, rheumatism, syphilis, malaria, &c.; hence the sleep disturbance in these diseases, and also that which follows the excessive use of tobacco, alcohol, &c. In the latter class the patients get to sleep quickly, to awake at two or three in the morning, to lie awake for some hours; and they are often awakened by slight external excitations.

Sleeplessness may be originated by sensory stimuli, which cause contraction of the peripheral and dilatation of the cerebral blood-vessels, acceleration of the heart's action, and an increase of arterial tension. They also cause dilatation of the pupils, and change the character of the respirations; these become deeper, quicker, and more abdominal. Consciousness of external things can alone be aroused by impressions transmitted to the brain textures (themselves insensitive) becoming converted into sensations and ideas through the agency of the mind. When excitations are of sufficient intensity to cause sensations wakefulness is inevitable. Excitations may be instigated in the most varied ways; they include pain of all kinds, and many impressions arising out of digestive and other derangements. They affect the neurasthenic, gouty, and rheumatic unduly.

It is evident that successful treatment depends on accuracy of diagnosis. In each and every case the sleeping conditions of the sufferer should be attended to. Exercise and food should be proportionate to the body and to the strength of digestion. The *primæ viæ* and the state of the skin must not be neglected. A good habit of sleep should be assiduously cultivated. In sleeplessness due to mental causes change of work should be advised, that new centres may be called into operation, and the overwrought ones correspondingly relieved. It is in these cases alone that devices for getting to sleep, such as the monotonous counting of figures, sheep, &c., are efficacious. In bad cases the judicious use of pure hypnotics is helpful; they force the mind into oblivion. Drugs like barbitone and chloral hydrate, which act chiefly on the brain centres that function thought, and induce sleep that closely resembles natural sleep, are called pure hypnotics, in contradistinction to many substances, as narcotics, analgesics, anodynes, soporifics, &c., that arrest pain, diminish sensibility, and disturb in a pronounced manner the functions of the brain and nervous system.

When wakefulness is due to neurasthenic conditions, tonics, increased nutrition, the abandonment of excesses, change of air and scene are indicated; electricity and suitable baths are useful adjuncts; hypnotics should be sparingly employed. Sleeplessness due to hyperæmic conditions of the brain is to be met by sedative treatment; that which depends on anæmia, by tonics, &c. In both, posture during sleep will repay attention. That which originates from gouty, rheumatic, syphilitic, and like poisons only yields to the alleviation of the constitutional state.

In sleeplessness due to sensory stimuli and pain, care must be taken to ensure the removal or mitigation of these, that the sleep they prevent may supervene. Medicines—analgesics or anodynes—

such as belladonna, should be first selected, for they act as indirect hypnotics by operating chiefly on the nerve-terminals. When such remedies fail, narcotics, as morphine and opium, are called for; they not only lessen perceptivity in the brain and sensitivity in the nerve-endings, but they diminish the conductivity of the nerves. Such wide-reaching drugs have many disadvantages in such cases, but pure hypnotics are useless. Hypnotics, narcotics, and sleep-inducing medicines should never be taken except under medical advice. To drug the brain into quiescence without remedying the cause of the cerebral activity will in many cases only aggravate the evil, for they will be complicated by a drug-taking habit. In most instances drugs are best avoided.

Good bibliographies of this subject are to be found in Copeland's *Dict. of Med.* (vol. in. pt. 2, Lond. 1838); in *Dict. Encycl. des Sciences Médicales*, art. 'Sommeil' (ser. iii. tom. 10, 1881); also in Neale's *Medical Digest* (Lond. 1891). The following may be consulted in connection with the physiology of sleep. Cappie, *The Intracranial Circulation* (Edin. 1890); Carpenter, *Mental Physiology* (Lond. 1874); Durham, *Physiology of Sleep* (Guy's Hosp. Reports, 1860); Fleming, 'On Sleep,' *Brit. and For. Med. Chir. In *Plants*, sleep is one of the phenomena of irritability. Light acts on plants as a powerful stimulus, essential to their active and healthful vegetation. When it is withdrawn the flowers of many plants close, and the greater number show a tendency to it, whilst leaves more or less decidedly incline to fold themselves up. The leaf-stalk also generally hangs down more or less, although in some plants it is more erect during sleep. The sleep of plants, however, is not always nocturnal. The flowers of some open and close at particular hours of the day. Thus, the crocus is a morning flower, and closes soon after mid-day; whilst some flowers expand only in the evening or during the night. It was Linnæus who first observed the sleep of plants in watching the progress of some plants of *lotus*, the seeds of which he had sown. The periodic movements of plants, of which sleep is one, have various uses. The opening of flowers in the morning and the closing in the evening are related to pollination. See PLANTS (*Movements*), and PHYSIOLOGY (VEGETABLE).

Sleeping-sickness, the European name for a malady long endemic on the Congo and the west coast of Africa, has of late years appeared in Uganda, where it has proved very fatal. It has been ascertained to be due to the presence in the blood of a parasite of the genus *Trypanosoma*, which is communicated by the bite of one or more species of Tsetse (q.v.).

Sleepy-sickness is a popular name for Encephalitis lethargica (q.v.).

Sleidanus. JOHANNES, historian, was born at Schleiden, in the neighbourhood of Aachen in 1506, and having been trained to the law he entered the service (1537) of Francis I. of France. But becoming a convert to Protestantism he was dismissed (1541); and for the rest of his life he was ambassador of the Protestant princes of Germany, and represented them at the court of England and at the Council of Trent. He died at Strasburg on 31st October 1536. His name lives as the author of a history of the reign of Charles V.—a well-written, impartial work entitled *De Statu Religionis et Reipublicæ Carolo V. Cesare Commentarius* (1555; best ed. Frankfurt, 1785–86, 3 vols.). Baumgarten edited the Letters of Sleidanus (1881) and wrote a Life of him (1878).

Sleighs. See SLEDGES.

Sleswick (Ger. *Schleswig*; Dan. *Slesvig*), a region divided in 1920 between Prussia and Denmark. Area of Danish province (South Jutland), including the island of Rømø (Röm), 1598 sq. m.; area of Prussian province of Schleswig-Holstein, including the islands of Heligoland, Sylt, &c., and the former duchies of Holstein and Lauenburg, 5802 sq. m. Sleswick is separated from Holstein (q.v.) by the river Eider and the Kiel Canal. The whole region belongs to the alluvial peninsula of Jutland, its eastern half being an undulating plain and its western a series of low-lying but very fertile marsh-lands, protected from the ocean by sea banks. The eastern coast (230 miles) is deeply indented by several long narrow arms of the sea called fjords, some of which make excellent harbours, and alongside it lie the large islands of Fehmern (in Germany) and Alsén (in Denmark). The western coast is more regular, but very low; and a string of low islands (Rømø assigned to Denmark; Sylt, Föhr, Pellworm, Nordstrand, and others remaining German) and sandbanks stretching right in front of it protect it to some extent from the waves of the North Sea. The chief occupations of the people are agriculture, cattle-feeding, ship-building, and navigation. Corn and fat cattle are exported, the latter (of an excellent breed) in large numbers to England. Fishing is carried on in the inlets of the Baltic, and there are profitable oyster-beds amongst the sandbanks of the North Sea. Flensburg is the chief seaport of Sleswick. Pop. of undivided Sleswick-Holstein (1910) 1,621,004; pop. of the Danish province (1921) 163,622 (mostly Danes); of the Prussian province of Schleswig-Holstein (1925) 1,518,164. The capital of the latter is Kiel. Protestantism is the religion of the vast majority.

At the dawn of history Sleswick was inhabited by the Cimbri; they were succeeded by the Angles, Jutes, and Frisians. But the greater part of the Angles crossed over into England, and their place was taken by Danes. When Charlemagne reduced the Saxons to his sway the Danish king built a wall from sea to sea alongside the Eider, the southern frontier of his domains, to protect himself against the emperor's attacks. And from that time (808) for 350 years Sleswick alternated between the Danish and the imperial yoke, its duke paying homage sometimes to the king of the Danes, sometimes to the German emperor. In 1157 the duchy was definitively united with the Danish kingdom. Meanwhile Holstein to the south was conquered and christianised by Charlemagne and his successors, and the countship of Holstein formed in 934 by the German king Henry I. Between 1157 and 1225 this southern part of the peninsula was subject to the rule of Denmark. From the year 1386 the Danish duchy of Sleswick and the German countship of Holstein had one common ruler, the Count of Holstein having fallen heir

to the former dignity in that year. About fifty years earlier a compact had been made, the *Constitutio Waldemariana*, by which it was solemnly agreed that the crown of Denmark and the duchy of Sleswick should not in future be held by the same individual ruler. In spite of this agreement, however, King Christian I. of Denmark possessed himself of both Sleswick and Holstein, and, having in 1474 acquired from the Emperor Frederick III. the suzerainty of Ditmarsh, he converted the countship of Holstein into a duchy. The sons of the next Danish king divided his territories amongst them after his decease, and their immediate successors still further subdivided them; but eventually they were all gathered up again (1581) under the heads of the royal line (Glückstadt) and the ducal line (Gottorp). The latter held Sleswick as a fief of Denmark and Holstein as a fief of the German empire; nevertheless the king of Denmark ruled in several detached portions of both duchies.

Ten years after the conclusion of the Thirty Years' War the Duke of Sleswick (Frederick III.), backed by his son-in-law Charles X. of Sweden, declared himself an independent and sovereign prince. This the Danish kings all along resented, and at length, when Charles XII. of Sweden was routed at Pultowa, Frederick IV. of Denmark grasped (1721) the opportunity, invaded Sleswick, expelled the duke, and seized his territories in that duchy. The heads of the ducal line became, one in 1751 king of Sweden, the other (the nominal duke) in 1762 emperor (Paul III.) of Russia, and soon ceased to take any interest in Sleswick-Holstein, the whole of which (both duchies) was formally given up to the king of Denmark in 1767. On the dissolution of the German empire in 1806 Holstein was united with the Danish crown, but was reincorporated in the German Confederation by the Congress of Vienna in 1815. From 1767 the Danish sovereigns had steadily endeavoured to make the duchies thoroughly Danish and to reduce them to complete dependence upon the Danish crown. At length in 1846 King Christian VIII. proclaimed that the law of succession in Sleswick should be the same as for the Danish crown—in other words, that Sleswick was to be made an integral part of the Danish kingdom. This action, as well as the refusal of the king to summon the common estates of the joint duchies, was warmly and actively resented by the people of Sleswick and by the German party in both Sleswick and Holstein. At length (March 1848) the latter, headed by Count Reventlow and Prince Frederick of Augustenburg, rose in revolt. They found a zealous supporter in Frederick William IV. of Prussia, who made himself the executive agent of the German Confederation. War began in March 1848; several severely contested battles, as at Düppel, were fought before peace was made in the end of 1850. Through the intervention of Austria matters were for a time put on a footing satisfactory to the people of the two duchies—so far at least as fair words and fine promises could go. The Danes, however, still pursued their policy of forcible denationalisation in both Holstein and Sleswick. The death of King Frederick VII. of Denmark in the end of 1863 brought the question of succession to a crisis; for Frederick of Augustenburg proclaimed himself Duke of Sleswick, to which title the new king of Denmark likewise laid claim. Austria and Prussia called upon Duke Frederick to abdicate and leave the duchy, and forbade Denmark to proclaim a constitution for it. Both refused to obey. Thereupon the two powers took up arms against the northern kingdom, and after a short but decisive campaign wrested both Holstein and Sleswick from the Danes. How they divided their conquest between them, and then

quarrelled over the division, and how Austria came out of the conflict thoroughly woisted, has been already told under Germany (q.v.). From the conclusion of that war (1866) to 1920, Sleswick-Holstein constituted a province of Prussia. In the northern part of Sleswick, mainly Danish in population, German measures, such as the compulsory use of the German language in schools, &c., were considered oppressive, but the agitation for incorporation with Denmark more or less died down after the treaty of 1907, which settled the quarrel over the Danish 'optants,' who were refused citizenship by both countries, till it was revived by the Great War and by the creation of many new states on the principle of self-determination. Under the Treaty of Versailles a plebiscite was agreed on, and Sleswick was divided for the purpose into three zones. The northern zone voted as a whole; the middle by communes; and the southern (along with Holstein) was left in undisputed possession of Germany. The northern zone voted for Denmark in the proportion of 3 to 1; the second zone for Germany by 4 to 1 (Flensburg, 3 to 1; the remainder, 6½ to 1). Curiously enough the strongest German vote was in the Frisian communes (over 27 to 1). Germany thus lost the northern zone only.

SLESWICK, the former capital of Sleswick-Holstein, stands on the Schlei inlet of the Baltic, 28 miles NW. of Kiel. It was a great trading town in the 9th century, and has a Gothic cathedral (13th century) with a fine high altar (1514-21), and the Gottorp (q.v.) Castle. There are tanneries and fisheries. Pop. 20,000.

Slevogt, MAX, German artist, was born in 1868 in Bavaria. With a fantastic and whimsical style that is very charming, he has specialised in lithography and wood-cuts, after doing much illustrative work for *Jugend* and *Simplicissimus*. He has been termed the 'Mozart of drawing, with a spark or two of Watteau.'

Slickensides are the smooth, polished, or striated, and generally glazed surfaces of joints and faults in rocks. They are considered to have been produced by the friction of the two surfaces during the movement of the rock. Slickensides are often coated with a deposition of calcite, hæmatite, chalcedony, or other mineral matter, which takes the form of the grooves and striæ and thus often looks as if it had been striated. See **FAULT**.

Sliding Scale. See **CORN LAWS**; **PROFIT-SHARING**; **TRADE UNIONS**.

Sligo (Irish *sligach*, 'shelly river'), a maritime county of Connaught, with an area of 442,295 acres. Pop. (1841) 180,886; (1861) 124,845; (1881) 111,578; (1901) 84,022; (1911) 79,045; (1926) 71,393, mostly Roman Catholics. The surface rises gradually from the coast as far as the Benbulbin range (2072 feet) and the Slieve Gamph. There are some picturesque lakes, and three of the streams are to some extent navigable. The greater portion of the county is on Carboniferous Limestone. On both sides of Slieve Gamph—a metamorphic ridge—conglomerate and Old Red Sandstone appear, skirting the older formation. Iron, copper, lead, silver, and barytes occur. There is fishing on the coast, but the chief occupation is agriculture; tillage has been superseded by pasturage and cattle-feeding. About half the total area is under grass; a fourth part is uncultivable. The bulk of the holdings range between 5 and 30 acres each. Numerous co-operative creameries have been formed. The county was anciently the seat of the O'Connors. There is a group of rude stone monuments at Carrowmore near Sligo, another at Highwood overlooking

Lough Arrow; the remains of a round tower and a beautiful 10th-century cross at Drumcliffe; ruins of ancient abbeys at Ballysadare, Banada Court, and Ballindoon; numerous cashels, raths, souterrains, and some fine castles in ruins. The island of Inishmurray has the remains of an early Christian establishment planted inside an old pagan cashel or rude stone fort.

SLIGO, chief town of the county, stands on the Garvogue, which is spanned by two bridges, 137 miles NW. of Dublin by rail. Pop. 10,000. The town contains a Roman Catholic cathedral, the church of the Dominican Friars, and other places of worship, a Bishop's Palace (Roman Catholic), college, two convents, prison, hospitals, workhouse, two police barracks, town-hall, county court, and the lunatic asylum for the counties of Sligo and Leitrim. Sligo has the termini of three railways, and its port has been much improved. A shirt and clothing factory gives employment. The corn-mills supply five counties with ground maize, oatmeal, and flour; and there are important salmon-fisheries here and at Ballysadare.

Sligo was the scene of some of St Patrick's first missionary efforts, was plundered by the Danes, and often burnt and pillaged. There are traces of an old castle and fort. The beautiful ruins of a Dominican abbey, founded in the 13th century by the Earl of Kildare, still remain. Sligo, besieged by the parliamentarians in 1641, was captured and lost again by the adherents of William III.; constituted a borough by James I. in 1612, it returned two members to the Irish House of Commons. The Act of Union left it one member, and it was disfranchised in 1870.

Slings, as weapons, differed little from the familiar toy. But slings fastened to the end of a short pole were capable of discharging a bolt with such force that at 500 yards distance it could pierce a helmet or a thin shield. The sling was used in the Persian wars. The Balearic islanders were counted of old the most expert with the sling, which was more recently a favourite weapon of several semi-savage peoples, notably the Tahitians in the Pacific. Slings were used by the besiegers during the defence of Chitral; see Sir G. S. Robertson's *Chitral* (1898).

Slip, in a dockyard, is a smooth inclined plane, sloping down to the water, on which a ship is built. It requires a very solid foundation. For the repair of ships of comparatively moderate size slips consist of a carriage with blocks, as in a graving-dock, working on an inclined railway extending for some distance beyond high-water to a sufficient depth below low-water of spring tides to enable vessels to be floated on the carriage. When the vessel is floated over and grounded on the cradle powerful hauling gear, worked by steam or other power, is set in motion to draw the ship out of the water. Slipways are useful adjuncts to shipping ports, and for vessels up to 2500 tons register they are better than a dry-dock, as better light is afforded for making repairs, and no pumping is needed; but this size is nearly the limit, though there is no good reason, if the slip and gearing be made strong enough, why larger vessels may not use slipways. The term slip is applied also to a jetty or pier sloping down from high-water to low-water, so that boats may land passengers readily at any state of the tide. See **DOCK**, **SHIPBUILDING**.

Slivno (Bulg. *Sliven*), or **SELMINIA**, a town of Bulgaria, at the southern base of the Balkan Mountains, 70 miles N. by W. of Adrianople, is celebrated for its annual fair. Arms, cloth, and attar of roses are manufactured. Population 28,000.

Sloane, SIR HANS, physician and naturalist, was born at Killyleage, County Down, 16th April 1660, the son of an Ulster Scot. He devoted himself to natural history and medicine, and in spite of an attack of hæmoptysis, which lasted from his sixteenth till his nineteenth year, he arrived in London in 1679 a well-read student. His apprenticeship to Stafforth, a pupil of Stahl, and his friendship with Boyle and Ray did much to encourage and advance him in his favourite studies. In France he attended the lectures of Tournefort and Duverney, and obtained on his return, by the active support of Sydenham, a footing in London as a physician. Already F.R.S., he spent over a year (1685-86) in Jamaica, collecting a herbarium of 800 species; and after his return became physician to Christ's Hospital (1694-1724), President of the College of Physicians (1719-35), Secretary to the Royal Society (1693), Foreign Associate of the French Academy (1708), and Sir Isaac Newton's successor as President of the Royal Society (1727). He had been created a baronet and physician-general to the army in 1716, and in 1727 was appointed royal physician. Though of remarkably delicate constitution, he lived to the great age of ninety-two, dying at Chelsea, 11th January 1753. His museum and library of 30,000 volumes and 3500 MSS., offered at his death to the nation for £20,000, formed the commencement of the British Museum (q.v.). He contributed numerous memoirs to the *Philosophical Transactions*, and published in 1745 a treatise on medicine for the eyes. But his great work was the *Natural History of Jamaica* (fol. 1707-25).

Sloe, or **BLACKTHORN** (*Prunus spinosa*), is generally a shrub of 4 to 10 feet high, but sometimes becomes a small tree of 15 to 20 feet. It is

Sloe (*Prunus spinosa*): a, fruit.

much branched, and the branches terminate in spines. The youngest shoots are covered with a fine down. The flowers are small, snow-white, and generally appear before the leaves. The fruit is ovate, or almost globose, pale blue with blackish bloom, and generally about the size of the largest peas. The sloe is abundant in thickets and borders of woods and hedgerows everywhere in Britain and almost all parts of Europe. The shoots make beautiful walking-sticks. Being spiny, the sloe is sometimes planted as a fence against cattle; but the roots having a habit of spreading and sending up suckers, hedges of it are troublesome to keep from encroaching on the fields. The bark is bitter, astringent, and tonic. The flowers, with the calyx, are purgative, and were once a favourite domestic medicine. The leaves are used for adulterating tea. The unripe fruit dyes black. The fruit, which is very austere, may be made into a preserve; and from it a kind of brandy may be extracted. An astringent extract of it, called *German Acacia*, was once much employed in cases of diarrhoea. The juice has been used to impart roughness to port wine and in the

fabrication of spurious port. The sloe of the southern United States (*P. umbellata*) has a pleasant black or red fruit.

Slonim, a town of Poland (by conquest from White Russia), 75 miles SE. of Grodno. Pop. 25,000.

Sloop is a one-masted cutter-rigged vessel, differing from a 'utter (q.v.), according to old authorities, in having a fixed bowsprit and some what smaller sails in proportion to the hull. The terms 'sloop' and 'cutter' appear, however, to be used nearly indiscriminately. In the British navy of the Victorian era a sloop-of-war was a vessel, of whatever rig, between a corvette and a gun-vessel, and ordinarily constituting the command of a commander. In the days of the sailing navy sloops-of-war carried from ten to eighteen guns; but from the introduction of steam the number of guns ceased to be distinctive. Under the new classification of the navy, the term sloop-of-war has been modified, the modern vessels designated sloops are the smallest type of cruiser, about 1400 tons or less and 15 knots speed, carrying three or four 4 in. guns and two anti-aircraft guns. In peace time they are used for showing the flag and police duties—in war time as mine-sweepers and escorts for merchant ships.

Sloth. These animals, which are referable to two genera (*Cholapus* and *Bradypus*), form a distinct family of the order Edentata. Their nearest allies are the armadillos and ant-eaters of South and Central America, to which countries the sloths also are restricted. They are exclusively arboreal animals and entirely vegetable feeders. In the forests which they inhabit it is quite unnecessary for them to descend to the ground in order to reach another tree, as the interlocking of the branches affords an easy passage. It has been asserted that when a sloth is absolutely compelled to walk upon

Two-toed Sloth (*Cholapus didactylus*).

the ground it acquits itself more creditably than might have been expected from an animal so conspicuously fitted for a purely arboreal life; though some authorities allege that it is quite incapable of progression upon the ground. The form of the animal is bulky and awkward; the fingers and toes are long, and furnished with long curved claws, which enable it to obtain and keep a firm hold upon the branches along which it crawls with the body hanging down. The two genera *Cholapus* and *Bradypus* are known respectively as the 'two-

toed' and 'three toed' sloths, from the number of toes upon the fore-feet. Neither genus has any incisor teeth; they have canines and molars with flat crowns, suitable for crushing vegetable food. The hair of the sloth is coarse and shaggy, and frequently of a dirty green colour, which is due not to any colouring substance in the hair, but to the presence of minute green Algae on the surface. The damp and warmth of the tropical forests probably favours the growth of these Algae, which disappear when the conditions are altered on the removal of the creature from its native forests. The long green hair combined with the lethargic habits of the sloth must be a protection to it against the attacks of jaguars and large snakes, which are its principal foes. This resemblance to a lichen-covered branch is strangely heightened in one species by an oval mark upon the back which bears the closest resemblance to the broken end of a branch. When the sloth is driven to take extreme measures it can use its teeth and claws to good purpose, and it has been even known to grasp a dog round the neck and strangle it.

Sloth Bear. See BEAR.

Slough. See SKIN, SNAKES.

Slough, a town of Buckinghamshire, 18½ miles W. of London and 2½ NNE. of Windsor. It has grown from a mere village since the railway epoch, and is a well-built place, the seat since 1863 of the British Orphan Asylum. Sir William Herschel lived at Slough from 1786 till his death, and his son, Sir John, thereafter till 1840. A huge dépôt for Government motor-cars, lorries, &c., was erected here during the Great War. Stoke Poges (q.v.) and the Burnham Beeches (q.v.) are near. Pop. (1861) 3425; (1901) 11,161; (1921) 16,392.

Slovaks, a branch of the Slavs (q.v.) who dwell in the mountainous districts of east Czechoslovakia (q.v.), and number in all about 2,000,000. They are a race of peasants, and live by cultivating the soil. In religion they are partly Lutherans, partly Roman Catholics. These people formed a constituent part of the ancient kingdom of Moravia, but were incorporated among the subject-lands of the Hungarian crown from the beginning of the 11th century to 1918. Their language is little more than a dialect of Czech, the speech of the Bohemians. Down to the end of the 18th century the Slovaks used Czech as their written or book language, but since that period certain patriotic writers—more notably the poets Holly, Chalupka, Sladkovitch, Hurban-Vajanský, and Hviezdoslav, the philologists Bernolák and Hattala, and the novelist Tomaschik—have tried to create a pure written Slovak literature. Their efforts have been opposed by Hungarians and Czechs.

Slovenians, a branch of the south Slavonic stock to which also the Serbs (Serbians) and Croats belong. The Slovenians are found mainly in Styria, Carinthia, and Carniola, and number in all about 1,250,000. They are sometimes called *Winds* or *Wends*, though distinct from the Wends (q.v.) of Germany. There is not much literature in the native speech apart from the 'Freising Fragments' (forms of confession and a sermon), dating from the 10th century, and 16th-century translations of the Bible, until we come to the end of the 18th century. Since the revival of the language which then took place the principal writers have been the poet-philologist Vódnik (1758–1819), the poets Prešern (1800–49), Vesel-Koseki, Aškerc (1856–1912), and Župančič (b 1879), the journalists Bleiweis and Janežič. See SLAVS, SERBIA.

Slow-match, generally rope steeped in a solution of saltpetre and lime-water, and burning at the rate of one foot per hour. Fort-fires are very

similar, but burn an inch a minute. They were used for firing guns before the introduction of friction tubes, and sometimes for firing military mines, &c. They were superseded by *Bickford's fuse*, a train of gunpowder enclosed in two coatings of jute thread waterproofed. See FUSE.

Slow-worm. See BLIND-WORM.

Sloyd (Swed. *sloyd*; cf. Eng. *sleight*), a system of manual instruction developed in the schools of Finland and Sweden, and largely adopted in other countries. The word properly denotes work of an artisan kind practised not as a trade or means of livelihood, but in the intervals of other employment. The fundamental idea of educational sloyd is to utilise this in a disciplinary way as an integral part of general education. To this end the older children are engaged in making articles of common household use varying from simple objects such as a flower-stick or a pen-rest to more complicated articles such as a cabinet or a small table. These objects are made from drawings or from models, but to exact measurements, and the utmost accuracy and finish are insisted upon. The tools employed are the ordinary tools of the carpenter, with certain exceptions, the most important of which is the knife. It is held that work of this kind is valuable, as supplementing and correcting the ordinary school education in the three R's. It fulfils the injunction 'to put the whole boy to school,' it develops faculties that are not otherwise exercised, it trains the eye, and in particular gives a general dexterity of hand. It utilises, as a means of education, the universal delight of children in making things, and it develops in a pre-eminent degree habits of self-reliance, order, accuracy, attention, and industry. It tends like gymnastics to the increase of physical strength, and it has a desirable effect socially, inasmuch as it fosters a liking for bodily labour and a respect for it. Above all it stimulates and exercises the practical intelligence or power of thought in dealing with things. To obtain these results the educational ends of sloyd must be kept prominently in view. The teacher accordingly ought to be a trained teacher who has acquired the requisite manual skill rather than an artisan, and the work ought to be properly graduated. Besides wood-sloyd, sloyd-work in iron and in cardboard (*papp-sloyd*) is also practised. There are also various systems of wood-sloyd differing in practical details. The main principles of sloyd had been advocated by many prominent educationists, and in particular by Herbart and by Froebel, of whose kindergarten system sloyd may be regarded as a continuation. But it was in Finland, on the reorganisation of the national system of education by Uno Cygnaeus, that manual work was first made a part of the regular instruction in the common schools. In Sweden this branch of education has been systematised and its principles expounded, chiefly by Herr Otto Salomon, director of the great slójd-seminarium at Nääs (instituted 1872).

Salomon's *Teachers' Handbook of Slójd* was translated and adapted for English teachers in 1891 by Mary R. Walker and W. Nelson, who also translated Alfred Johansson's *Practical Directions* (1892).

Slug, a name used for those land-molluscs of the order Pulmonata (air-breathing) in which the shell is rudimentary or absent. They have the same structure as the Snail (q.v.), but the shell, when present, is usually concealed beneath the mantle, though in some genera (e.g. *Urocyclus*) it is visible through an aperture in the mantle, while in others (e.g. *Helicario*) it becomes decidedly spiral and more exposed, so that it is impossible to draw any hard and fast line between the true slugs and the shell-bearing pulmonates or snails.

The mantle is usually an oval structure placed anteriorly on the back, with an orifice on its right side leading to the pulmonary cavity. In all slugs slime issues anteriorly from a mucous gland in the foot; in *Arion* and some others there is also a posterior gland. Slugs are divided into six families, each of which seems to have been evolved separately from a group of shell-bearing ancestors. The family Succineidae, in which the jaw has a quadrate accessory plate, contains both testaceous and shell-less genera, the latter being found in South America, the West Indies, and the Indian and Australian regions. The Vaginulidae, in which the male and female genital orifices are distinct, occur throughout the tropical regions of the world. The Limacidae, including the genera *Limax* and *Agriolimax*, are a family of almost world-wide distribution, known by the possession of a smooth jaw and aculeate marginal teeth. The Arionidae, the typical genus of which is *Arion*, have a usually ribbed jaw and quadrate marginal teeth; they are found most abundantly in Europe and North America, more sparingly in South America, Asia, and Africa, and not at all in Australia. The Testacellidae (including *Testacella*) and the Selenitidae, both of wide distribution, have all the teeth aculeate; the former are without, the latter with, a jaw. Over 500 species of slugs have been described, of which nineteen inhabit the British Islands. Of these three belong to *Testacella*, a genus possessing a small external shell on the posterior part of the body. The *Testacellae* are carnivorous, and devour earthworms, which they

Fig. 1.—Diagram of a Slug:

a, mantle; b, respiratory orifice; c, long horn with eyes; d, short horn; e, sole of the foot; f, posterior mucus pore; g, foot-fringe.

pursue underground. Four species belong to *Limax*—viz. the Great Gray Slug (*L. maximus*) and its ally *L. cinereoniger*, the Yellow or Cellar Slug (*L. flavus*), recognised by its yellowish colour and bluish tentacles, and the Tree Slug (*L. arborum*). Two species belong to *Agriolimax*, the

Fig. 2.—Slugs:

a, *Agriolimax agrestis*; b, *Arion*; c, *Arion empiricorum*, at rest; d, its eggs.

common Gray Slug of our gardens (*A. agrestis*) and the Brown or Marsh Slug (*A. lavis*), which is found in damp places. Two are of the genus *Amalia*, which differs from *Limax* in having the back sharply keeled. There are several of the genus *Arion*, differing from *Limax* in the more anterior position of the respiratory orifice, and the

possession of a caudal slime gland. The Black Slug (*A. ater* or *empiricorum*) is a very large species, varying much in colour, being black, white, black with white sides, black with a red fringe, brown, brown with yellow sides, red, gray, or yellow. The red variety is called the Red Slug, and was considered by Linnaeus a distinct species. The Striped Garden Slug (*A. hortensis*) is a small species common in gardens; it has the under side of the foot yellow or orange. The Irish Slug (*Geomalus mucosus*) is only found in County Kerry, Ireland, and in Portugal. Slugs do great damage to garden crops, and various methods have been devised for destroying them. They may be sought under stones or boards, or enticed by decaying cabbage-leaves, or collected while on the move at night, or in wet weather. They are readily killed by salt water. They lay their eggs, which often resemble small oval bags of jelly, in clusters in moist places. Slugs frequently climb trees, and some of them, especially the Tree Slug, have the power of descending by means of threads of mucus. The name Slug is often applied by gardeners to the larvæ of saw-flies (Tenthredinidae).

Slums. See HOUSING AND TOWN-PLANNING.

Sluys, a small town of Holland, province of Zeeland, 6 miles NE. of Bruges. In the middle ages it was a great seaport, the port of Bruges and Ghent, on an inlet of the North Sea now silted up, so that the town is now two miles from the sea. It is memorable for the naval battle fought off the shore between the English and the French on 24th June 1340, in which Edward III. won a brilliant victory.

Smack, a generic term for small decked or half-decked coasters and fishing-vessels. Most smacks are rigged as cutters, sloops, or yawls.

Smalcald. See SCHMALKALDEN.

Small-arms include all weapons that can be actually carried by a man. They are described under their respective heads, BAYONET, FIREARMS, REVOLVER, SPEAR (or Lance), RIFLE, SWORD. Small-arms are manufactured for the British government at Enfield and Birmingham.

Small Debts is a phrase current in Scotland to denote debts under £20, recoverable in the Sheriff Court (see SHERIFF). In England the same debts are recoverable in the County (q.v.) Court. See DEBT.

Small Holdings. See ALLOTMENTS, CROFTER, PEASANT PROPRIETORSHIP.

Smallpox, or **VARIOLA**, is one of the most formidable of the class of febrile diseases known as the *Exanthemata* (q.v.). The period of incubation (see under MEASLES) is generally twelve days. All cases of regular smallpox are divisible into three stages—viz. (1) that of the initial or eruptive fever; (2) that of the progress and maturation of the specific eruption; and (3) that of the decline. The course of an ordinary case of *discrete* smallpox—i.e. one where the pocks remain throughout distinct from each other—will first be described, and afterwards the other forms will be discussed. The *first stage* begins with rigors, followed by heat and dryness of the skin, a quickened pulse, furred tongue, loss of appetite, pain in the pit of the stomach, with nausea, vomiting, headache, and often pains in the back and limbs. The violence of the pains in the back, and the obstinacy of the vomiting, are frequently very well marked and characteristic symptoms. In children the disease is often ushered in by convulsions; while delirium sometimes attends its onset in adults. On the third day minute red specks begin to come out—first on the face (where they are always most numerous), then on the neck and wrists, and

on the trunk of the body, and lastly, on the lower extremities. These correspond to the incipient *pocks*, which can be felt like small shot under the skin, better, sometimes, than they can be seen. The fever, pain, sickness, &c. usually begin to subside as soon as the eruption appears, and by the beginning of the fifth day, when the eruption is generally fully out, and the *second stage* commences, have entirely disappeared. Upon the second or third day of the eruption a little clear lymph is seen in each pimple, which has increased considerably in size since its first appearance, and which is thus converted into a *vesicle*. The vesicles gradually increase in breadth, and, their contents becoming more and more yellow and opaque, are converted into *pustules*. These are at first depressed in the centre, but at their fullest development often become turgid and hemispherical. The suppuration on the face is complete by about the ninth or tenth day from the commencement of the fever, and the same process rapidly follows in the other parts of the body in the same order of succession as that in which the eruption originally appeared. The progress of the pustules is usually accompanied by swelling of the skin of the face, with a painful sensation of heat and tension; the scalp is often swollen; soreness of the mouth from a modified eruption there is often present; and the patient exhales a peculiar and disagreeable odour. About the eighth or ninth day of the disease a recurrence of the fever, known as the *fever of maturation*, or *secondary fever*, sets in, with a return of headache, restlessness, and sometimes delirium. The *third or declining stage* is little more than a period of convalescence. About the eleventh or twelfth day the pustules on the face become brown and dry at the top, or some of them break, and the fluid which oozes out solidifies into a yellowing crust; and from this time the process of *desiccation* goes on, the swelling of the face subsides, and at last only dry scabs remain, which gradually fall off about the fifteenth or sixteenth day. It is not till three or four days after the scabs have formed on the face that the same process is completed over the whole body. The scabs are usually completely gone by the twenty-first day, leaving behind them blotches of a reddish-brown colour, which sometimes continue for some months before they quite disappear; and some of the pustules, in consequence of ulceration of the true skin, may leave pits, especially on the face, which remain permanently. The period of scabbing is accompanied by various symptoms of improvement: the tongue becomes clean, the appetite returns, and by the time that the scabs have fallen off the patient may be regarded as restored to health; so that the entire course of a case of discrete smallpox occupies about three weeks.

Generally speaking, the severity of the disease is proportional to the number of pocks; and when these are so numerous as to run together on any part of the body, the disease is said to be *confluent*. This form differs in many important respects from that already described. The eruption is necessarily modified: the individual pocks are smaller, but by their coalescence they give the skin of the face an appearance 'like a mask of parchment,' and generally lead to much more scarring of the skin. Severe laryngitis and bronchitis, and ulceration of the corneæ, with consequent impairment or destruction of sight, are of frequent occurrence; and salivation is a usual symptom. But most important of all is the difference in the course of the fever. The remission described above in the first stage is slight, if it occurs at all; and the secondary fever, although on this account less conspicuous, is more severe, and much more dangerous to life.

Malignant smallpox is characterised by the severity of the onset, but particularly by the occur-

rence during the first few days of hæmorrhages under the skin, and from the various orifices of the body. Such cases are almost without exception rapidly fatal, sometimes so early that no sign of the characteristic eruption appears at all.

Modified smallpox, sometimes (but not happily) called *varioloid*, is the name applied to cases of the disease in which the eruption runs a less severe course than usual. They may be at first discrete or confluent; but the pocks abort either at the papular or the vesicular stage, or if they become pustular are small, and dry up with unusual rapidity. The constitutional symptoms are correspondingly less marked. This form of the disease with rare exceptions occurs only in those who have been vaccinated, or have had a previous attack of smallpox. The form of the disease which followed inoculation (q.v.) had a shorter incubation period (usually ten days), and a shorter and milder course; and the mortality was very much less than when it was contracted by infection.

The *cause* of smallpox is universally allowed to be a specific contagion, of whose nature we are in the most profound ignorance. There is probably no disease so contagious as this. Dr Haygarth stated (in 1793) that, during his long attention to this subject, not a single instance had occurred to prove that persons liable to smallpox could associate in the same chamber with a patient in the distemper without receiving the infection. The contagion acts either through the air, or by contact with the skin, or by inoculation; and the disease may be caused by the dead body, even when it has not been touched. What products of the diseased body are contagious is not exactly known, but the contents of the pustules and the dried scabs certainly are so. Opinions are divided as to the period at which the disease begins and ceases to be contagious. It is safest to maintain that it is capable of self-propagation as soon as the febrile symptoms have exhibited themselves. How soon the patient ceases to be dangerous cannot be decided with accuracy; but the stability of the contagious principle may be inferred from the fact that clothing will retain it for months, and it is said for years, when confined. Like all the contagious exanthemata, smallpox appears in an epidemic form, at irregular and, in our ignorance, it would almost seem capricious intervals. After an extraordinary exemption, perhaps for years, a district is suddenly invaded by it, and continues to suffer for a longer or shorter period, after which the disease spontaneously disappears—dies out, as it were—and does not reappear perhaps for years. Different epidemics vary very much in their severity, and isolated cases are usually milder than those occurring when the disease is epidemic. Race has much to do with the severity of the disease, the constitution of the dark races, especially the Negro, being singularly susceptible of the contagion, and exhibiting very little power of resisting the fatal tendency of the disease.

It is generally admitted that the discovery of *Vaccination* (q.v.); by which smallpox has lost much of its danger, is one of the great achievements of modern medicine. *Inoculation* (q.v.) protected the individual, but was liable to spread the disease, and sometimes caused fatal cases; while vaccination has the advantage of protecting both the individual and the community.

With regard to prognosis, it may be stated generally, it is a very fatal, and was formerly an extremely destructive disease—one death occurring in every four or five cases. Modified smallpox is very seldom fatal, although instances of death are occasionally reported. Smallpox is more fatal at the two extremes of life than in the intervening period, and is especially dangerous in pregnancy.

In olden times it was believed that the eruption was an effort of nature to get rid of the noxious matter, and hence heating and stimulating measures were adopted with the view of promoting the eruption. To Sydenham belongs the credit of first recommending an entirely opposite or cooling mode of treatment; but his suggestions met with the most strenuous opposition, and it was not till long after his death that the cooling treatment was fairly established. In mild cases, and in cases of modified smallpox, the physician has merely to guard the patient against hurtful influences, such as stimulating foods or drinks, too hot a room, or improper exposure to cold, and to prescribe cooling drinks during the fever, and occasional laxatives if they shall be required. In more severe cases the fever may be combated by saline purgatives, prescribed so as to produce two or three liquid stools daily, and by free ventilation of the surface of the body. When the eruption is all out, if the pimples on the face are few and distinct the danger may be regarded as over, and no further treatment is required. If, however, the disease assume a confluent form, wakefulness and restlessness are apt to come on about the eighth day, and soporific drugs may be administered with benefit. If the pustules are abnormally torpid in reaching their maturity, it may be expedient to administer strong broths, or even wine; and when the pustules are livid, and intermixed with Petechiae (q.v.), cardiac stimulants are necessary in addition, although the patient is then too often beyond the reach of help. During the secondary fever the bowels must be kept gently open, and hypnotic and soothing remedies are often required. A more nourishing diet is now called for, and wine should be given if the pulse is very weak. The external itching is partly relieved by opiates, but local applications are also employed: cold cream, or a mixture of ichthyol 10 per cent. in glycerin, may be thus used with advantage. Numerous special methods have been devised for the purpose of preventing the pitting or scarring of the face, which is often a hideous permanent disfigurement to the patient, e.g. boracic fomentations, but there is not yet sufficient evidence that any of them is uniformly satisfactory in its results.

During the period of desquamation an occasional warm bath may be prescribed with advantage; and the patient should always resort to this measure, as a precaution against carrying the contagion about with him, before again mixing in society.

The history of this remarkable disease is clothed in considerable obscurity. Its original habitat is quite uncertain; but there seems no doubt that it has been prevalent in India from a remote period, and in China since at least 200 years before the Christian era. It has been conjectured that it was one of the pestilences which occurred in Europe during the first and second centuries after that era; but the first accurate description of it is that of Rhazes, an Arabian physician, who flourished early in the 10th century. It appears to have reached England towards the close of the 9th century. After the Crusades it prevailed in most of the temperate countries of Europe, but did not reach the northern countries of Norway, Lapland, &c. for some time later. In 1517 it was carried from Europe to St Domingo; and three years later it reached Mexico, where it committed fearful devastations, and whence it spread with intense virulence throughout the New World. (According to Robertson, three millions and a half of people were destroyed in Mexico alone.) In 1707 it was introduced into Iceland, when more than a fourth part of the whole population fell victims to it; and it reached Greenland still later (1733), when it spread so fatally as almost to depopulate the

country. These cases are striking illustrations of the law that seems universally true, that a contagious disease is always most virulent on its first introduction to a new scene of action. At the present day the interior of Africa, and especially the upper basin of the Nile, seems to be the region where smallpox is most destructive. In Europe it is constantly present in most of the large cities; but during the 19th century—i.e. since the introduction of vaccination—epidemics were much less frequent and severe than before. The most intense and wide-spread was that of 1869-73 (see Report of Medical Officer of the Privy-council, 1874). Smallpox seems first to have been called by that name in the 15th century; *pockes* or *pox* (a contracted plural of *pock*) having come to be loosely used for several eruptive diseases, and especially for 'French pox' or syphilis. Till Sydenham's time measles and scarlet fever were frequently confounded with smallpox.

For smallpox in sheep, see SHEEP-POX.

Smalt. See BLUE, COBALT.

Smaragdite, a peculiar variety of Amphibole (q.v.), light grass-green in colour, with a foliated, lamellar, or fibrous structure. It occurs as a constituent of the rock called Eklogite.

Smart, CHRISTOPHER, a hapless English poet, was born at Shipbourne in Kent, 11th April 1722, and was educated at Maidstone, Durham, and Pembroke Hall, Cambridge, of which he was elected fellow in 1745. He won the Seatonian prize for an English poem on the attributes of the Supreme Being five times, and left college on his marriage to a step-daughter of John Newbery's in 1752. He now became a bookseller's hack, and made for some years a hard living betwixt improvidence, dissipation, and the expense of wife and children. His mind at last gave way, yet he lived on, with a few brief intervals of sanity, till his death in the rules of the King's Bench, on the 21st May 1771. Smart was assisted by Samuel Johnson in his monthly publication, *The Universal Visitor*, and the moralist preserved a kindly feeling for him in his misfortunes. 'I did not think he ought to be shut up,' he said to Burney. 'His infirmities were not noxious to society. He insisted on people praying with him; and I'd as lief pray with Kit Smart as any one else. Another charge was that he did not love clean linen: and I have no passion for it.'

Smart's works include a number of feeble epigrams, birthday odes, and occasional poems; the *Hilliad*—a heavy satire in answer to a criticism of [Sir] John Hill's; a bald prose translation of Horace (1756), well known to schoolboys; a poor poetical translation of *Phadrus* (1765), and a still poorer metrical version of the *Psalms* (1765), of the *Parables* (1768). His poems were collected in 1791, but the editor was careful to exclude the only thing that now claims a notice, *A Song to David* (printed 1763; ed. Blunden, 1924), some of the stanzas of which are said to have been scratched with a key on the walls of his madhouse. The poem extends to a hundred stanzas, and is marred by repetitions, and grievous defects of rhythm and structure, but it shows a genuine spark of true poetic inspiration not common in its age, and it is not too much to say that the poor poet here for once 'had reached the zenith from his madhouse cell.' Rossetti called it 'the only great accomplished poem of the last century . . . A masterpiece of rich imagery, exhaustive resources, and reverberant sound.'

Smart, HENRY (1813-79), composer, nephew of Sir G. T. Smart (1776-1867, organist to the Chapel Royal), was educated for the law, but early became famous as an organist. His more ambitious compositions (operas, cantatas) have not held their ground, but he is still known for

his organ works, part songs, and church music. See the Life by Sparks (1880).

Smartweed, a name given to some plants of the genus *Polygonum* (q.v.) on account of their acrid properties; especially *Polygonum Hydropiper*, or Water-pepper.

Smeaton, JOHN, an eminent civil engineer, was born at Aushorp near Leeds, 8th June 1724, and early showed a bent towards mechanical pursuits. On leaving school, where he excelled in geometry and arithmetic, he entered his father's office as law clerk; but his heart was not in his work, and about 1750 he removed to London, to commence business as a mathematical instrument maker. In the following year his experiments in mechanical invention were resumed. His improvements on mill-work gained him the Copley Medal of the Royal Society in 1759. In 1753 he was chosen a member of the Royal Society; and in the following year he visited the Netherlands, and inspected the engineering works of that country. In 1753 the second wooden lighthouse on Eddystone (q.v.) rock was destroyed by fire, and the re-erection of the work was entrusted to Smeaton. The new lighthouse was built of stone (1756-59), and this great work, the greatest of its kind hitherto undertaken, remained for 120 years a stable monument of Smeaton's engineering skill, till the erection of the new Eddystone close by (1879-82). Even after his great achievement Smeaton seems to have had little employment, as he applied for and obtained in 1764 the post of 'receiver of the Derwentwater estate;' and this situation he held till 1777, by which time he was in full professional employment. The chief of his other engineering works were Ramsgate harbour (1774); the Forth and Clyde Canal; several important bridges in Scotland (Perth, Banff, Coldstream), together with an immense amount of mill-machinery. He also improved Newcomen's steam-engine. He was in constant attendance in parliament during a large portion of his life. In 1783 his health began to decline, and he retired from active business, dying at Aushorp of paralysis, 28th October 1792. In 1781 Smeaton wrote a *Narrative of the Construction of the Eddystone Lighthouse*. The Society of Civil Engineers published posthumously his numerous professional Reports (3 vols. 1797), which were regarded by his successors 'as a mine of wealth for the sound principles which they unfold, and the able practice they exemplify.'

See a *Short Narrative of John Smeaton* (1793); and *Smiles's Lives of the Engineers* (new ed. 1904-5).

Smectymnus, a name compounded of the initials of the following five divines: Stephen Marshall, Edmund Calamy, Thomas Young, Matthew Newcomen, and William Spurstow, joint-authors of *An Answer* (1641) to Bishop Hall's *Humble Remonstrance to the High Court of Parliament* (1641), in defence of the liturgy and episcopal government. Of the five authors, the chief was Thomas Young, Milton's tutor.

Smederevo. See SEMENDRIA.

Smedley, FRANCIS EDWARD, novelist, was born in 1818 at Marlowe. Always deformed, he took early to writing, his half-dozen works including *Frank Fairleigh* (1850), *Lewis Arundel* (1852), and *Harry Coverdale's Courtship* (1855). Bright, cheery books, these appeared originally in *Sharpe's Magazine*, of which Smedley for two years was editor, and they were illustrated by Cruikshank and 'Phiz.' He died in London, 1st May 1864.

Smeinogorsk. See ZMEINOGORSK.

Smell. See NOSE, SENSATION.

Smelling Salts. See SALTS.

Smelt (*Osmerus*), a genus of Salmonidæ, or of

a distinct family, Argentinidæ. The dentition is peculiar—e.g. in the canine-like character of some of the teeth, and in the presence of a row on each side of a groove in the roof of the mouth. The Common Smelt (*O. eperlanus*), called *Spirling* or *Spurling* in Scotland, and *Eperlan* in France, is a fish of 8 or 10 inches (rarely 12 inches) in length. The form is very trout-like, but rather more slender; the tail is larger in proportion, and more forked. The lower jaw is longer than the upper. The back is whitish, tinged with green; the upper part of the sides shows bluish tints, the lower part of the sides and the belly are of a bright silvery colour. The smelt has a peculiar, cucumber-like smell, and a delicious flavour, on account of which it is highly esteemed for the table. From the sea smelts often ascend estuaries and rivers, and they thrive well in lakes and ponds. The same is true of the common American species—*O. mordax*. A third species—*O. thaleichthys*—of smaller size occurs on the Pacific coasts of North America, and another—*O. dentex*—on the corresponding Asiatic coasts. The name smelt is sometimes extended to related genera—e.g. *Argentina*, *Retroinna*, and the Pacific surf-smelts (*Hypomesus*).

Smelting. See COPPER, IRON AND STEEL, &c.

Smeru, or SEMRU, the highest mountain of Java near the eastern end of the island. It is 12,240 feet high, and is an active volcano.

Smerwick, a peninsula and bay in County Kerry, Ireland, where in July 1579 Sir James Fitzmaurice landed, by authority of the pope, with a number of Italian and Spanish soldiers. They entrenched themselves within a fort, but in November were overpowered and put to the sword, to the number of six hundred, by Lord-deputy Grey and young Walter Raleigh. This gruesome story is introduced into Kingsley's *Westward Ho!*

Smetana, BEDŘICH (1824-84), pianist and composer, was born at Leitomischl in Bohemia, and studied music under Proksch; he taught and directed concerts, mostly in Prague, and was conductor at the National Theatre there from 1866 till 1874, when he lost his hearing. His compositions include the operas *The Bartered Bride* (1866), *Dalibor*, *Libuše*, *Two Widows*, *The Kiss*, *The Secret*, the cycle of six symphonic poems *My Country* (1874-79), and the string quartet *From My Life*. Many of his works, characterised by splendid vigour, spontaneity, and often by a certain refreshing humour, deal with episodes of Czech life and history (though never actually employing folk-tunes), and he is regarded as the founder of the modern Czech school of music. There are studies in French by Ritter (1907), and in German by Rychnovsky (1924).

Smethwick, a municipal (1899), county (1907), and parliamentary borough of Staffordshire, about 3 miles west of Birmingham. There are important iron, glass, chemical, and machine works. Pop. (1891) 36,100; (1901) 54,539; (1921) 75,757.

Smew. See MERGANSER.

Smilax, a genus of Liliaceæ, or according to some (on account of anatomical differences) of a separate family Smilacaceæ. It consists of herbaceous or half-shrubby plants, generally climbing, with net-veined leaves having tendrils at the base, six stamens, a free three-celled ovary, three stigmas, and a roundish berry. The typical genus (*Smilax*) is the most important of the tribe. The Sarsaparilla (q.v.) of commerce is the product of the roots of several species of *Smilax*; and the large fleshy tubers of *S. China*, a native of China and Japan, are nutritious and used for food. *S. Pseudo-china*, an American species, has similar tubers, which are used for making beer and for fattening hogs in some parts of the United States.

Smiles, SAMUEL, author of *Self-Help*, was born at Haddington in 1812. His family owed much to the intelligence, shrewdness, and force of character of their mother, who, when left a widow with a family of eleven, continued successfully to conduct a small business. Samuel Smiles had artistic leanings, but studied medicine in Edinburgh, took his degree when he was twenty, and published at his own expense a work on *Physical Education* (1838). At first he practised in Haddington as a medical man with small success, lectured on chemistry, and wrote articles for an Edinburgh newspaper. He settled as a surgeon in Leeds, but abandoned this for the editorial chair of the *Leeds Times*. He became secretary of the Leeds and Thirsk Railway Company in 1845, and in 1854 secretary of the South-Eastern Railway, retiring in 1866. While at Leeds he came into contact with George Stephenson, and conceived the idea of writing his life, a work which he eventually accomplished (1857). *Self-Help* followed in 1859, and was soon an assured success, 20,000 copies being sold during the first year, and up till 1889 the sales had reached 150,000 copies, while the book had been translated into seventeen languages. Some young men in Leeds who met in the evening for self-education had asked Smiles 'to talk to them a bit,' though really written before, it was only after the success of Stephenson's life that *Self-Help* appeared. Henceforward his career was that of a popular author and compiler, varied by travel to the scenes of the labours of the characters he described. He recovered from an attack of paralysis in 1871; was made LL.D. by Edinburgh in 1878; and lived till the 16th of April 1904, leaving an *Autobiography* to be published in 1905.

To the *Self-Help* series of books he added *Character* (1871), *Thrift* (1875), *Duty* (1880), and *Life and Labour* (1887). Works which teach the same truths by example are *Lives of the Engineers* (1861); *Industrial Biography* (1863); *Lives of Boulton and Watt* (1865); *Thomas Edward* (1876); *George Moore* (1878); *Robert Dick* (1878); *James Nasmyth* (1883); *Men of Invention and Industry* (1884). Besides contributions to the *Quarterly Review*, he also published *The Huguenots in England* (1867), and *The Huguenots in France* (1873); *A Publisher and His Friends: John Murray* (1891); and *Jasmin, the Barber-poet* (1891).

Smillie, ROBERT, miners' leader and Labour member of parliament, was born of Scottish parents in Belfast in 1857. At the age of 14 he worked in a Govan shipyard; at 16 he began his career as a Lanarkshire coalminer. Engaging early and actively in trade union work, he was from 1894 to 1918 president of the Scottish Miners' Federation, from 1912 to 1921 of the Miners' Federation of Great Britain, and again from 1921 of the Scottish Federation. A good fighter and a trusted leader, he was yet unsuccessful as a parliamentary candidate until 1923, when he was elected for Morpeth. See his *My Life for Labour* (1924).

Smirke, SIR ROBERT, architect, was the son of Robert Smirke (1752-1845), a well-known painter and book-illustrator, and was born in London in 1781. He became R.A. in 1811, was architect to the Board of Works, and was knighted in 1831. He died at Cheltenham, 18th April 1867. Smirke's public buildings are usually classical, his domestic dwellings Gothic. London is full of his work. Covent Garden Theatre (1809) was his first great undertaking; the British Museum (1823-47) the greatest. Others of his buildings are the Mint, the Post-office, several of the clubs (including the Carlton), the College of Physicians, King's College, and courts of justice in various parts of the country. He was entrusted with the restoration of York Minster after the fire (1829). Lowther Castle is a specimen of his domestic architecture. His brother Sydney Smirke, R.A. (1799-1877), was associated with him in some of his labours.

Smith, one of the oldest and most wide-spread of English family names, not to be regarded as belonging to one but to very many distinct families. It is, of course, derived from the honourable trade of the smith; the smith being originally a worker in metal or wood, and so nearly equivalent (when not compounded as in goldsmith, locksmith, arrow-smith) to 'craftsman' or 'artificer.' At first the name was not hereditary, but was used as a description of the individual: in the 14th century we have John Smyth, son of Thomas Wight (John being a smith and Thomas a carpenter); John's son might be called William Smythson, and his daughter Mary Smythdoghter. But soon the name became purely hereditary; and it is obvious that there would be many founders of Smith families. Philip le Smethe, William le Smyt, Henry le Smeyt show ancient forms of the name; Smyth, Smythe, and Smijth (derived from a form with a dotted y, Smyth) are also old variants which still survive. Smithson, Smithman, Brownsmith, Redesmith, Nasmyth (= Nail-smith), &c. are derivative forms. Corresponding in meaning are the Latin *Faber*; French, *Le Fevre*, *Lefevre*, or *Lefebvre*; Italian, *Fabroni*; German, *Schmidt*; Dutch, *Smid* and *Smits*. The Celtic *Caird* and *Gow* are nearly equivalent. The English names *Fenier*, *Ferrers*, *Ferrars* are from the Latin *Ferrarius*, 'farrier' or 'shoesmith.' See NAMES.

In the London directory the Smiths fill seven pages (averaging 200 entries) of the commercial section (as against three and a half pages of Joneses, and three of Browns); in Edinburgh Smiths and Browns are about equal, while Jones is among the rarer names. In English literature they constitute a mighty army: Allibone's *Dictionary of British and American Authors*, with its supplement (1891), enumerates no less than 1069 several and distinct authors of the name of Smith (seventy-five of them William Smith), without counting Smythes, &c. The editor of the *Dictionary of American Biography* has thought no less than 199 persons of the name worthy of notice in that work. To such exhaustiveness the present work cannot pretend; but besides the subjects of the articles below, we add a list of Smiths whose names are more or less familiar in philanthropy, literature, science, or art.

Anker Smith, engraver (1759-1819); Charles Piazzi Smyth, astronomer-royal for Scotland (1819-1900); Charles Roach Smith, antiquary (1807-90); Charlotte Smith, poet and novelist (1749-1806); Eli Smith, American missionary to Syria (1801-57); Sir Francis Pettit Smith, mechanical inventor (1808-74); F. E. Smith, Lord Birkenhead (b. 1872), Lord Chancellor 1919-22, Secretary for India from 1924; George Smith, of Chichester, landscape-painter (1713-76); Rev. Sir George Adam Smith, Principal of Aberdeen University (b. 1856); Gerrit Smith, American philanthropist (1797-1874); Henry Boynton Smith, D.D., American Presbyterian divine (1815-77); James Smith of Deanston, Scottish agriculturist (1789-1850); Sir James Edward Smith, botanist (1759-1828); John Smith, mezzotint engraver (1652-1742); John Raphael Smith, painter and mezzotinter (1750-1812); John Pye Smith, D.D., LL.D., divine and geologist (1774-1851); John Stafford Smith, composer (1750-1836); Robert Angus Smith, Scottish chemist and hygienist, author of *Air and Rain*, &c. (1817-84); Robert Archibald Smith, composer of Scottish songs and psalm-tunes (1780-1829); Sir Thomas Smith, Elizabethan statesman and scholar, author of *De Republica Anglorum* (1514-77); Thomas Smith, of Derby, painter (c. 1709-67); Thomas Southwood Smith, M.D., hygienist, author of *Philosophy of Health and Epidemics* (1788-1861); Sir William Alexander Smith, founder of Boys' Brigades (q.v.; 1854-1914); William Henry Smith, author of the philosophical novels *Thorndale* and *Gravenhurst* (1808-72).

Smith, ADAM, the founder of political economy as a separate branch of human knowledge.

was born in the town of Kirkcaldy, Fife, on 5th June 1723. His family belonged to the respectable middle class; his father was comptroller of the customs at the port of Kirkcaldy, and his mother, Margaret Douglas, was the daughter of a small Fife-shire laird. His father died a short time before his birth, and the boy was the object of the care and solicitude of a widowed mother, to whom he was closely attached, and who lived to be proud of his attainments. When he was no more than three years old the poor woman got a sad fright, from a calamity hardly known at the present day—the child was stolen by tinkers; but he was tracked and recovered by his uncle as they were seeking a hiding-place in the neighbouring wood of Leslie. This was the only adventure in his quiet life. After getting the usual burgh-school education in Kirkcaldy, he was sent, in 1737, to the university of Glasgow, where he seems to have devoted himself mainly to mathematics and natural philosophy, though Hutcheson was the professor of moral philosophy. He secured an exhibition on the Snell foundation, which took him to Balliol College, Oxford, where he studied for seven years, and left traditions as of a man of large acquirements and peculiar independence of thought. It is said that he was intended for the English Church, but if so his own convictions crossed the designs of his friends. He returned to Kirkcaldy, and lived for a while with his mother there in undisturbed seclusion and study. In 1748 he came to Edinburgh, where silently and unostentatiously he became one of the brilliant little circle of men of letters who were then rising to importance, amongst his friends being David Hume, John Home, Dr Hugh Blair, Lord Hailes, and Principal Robertson. In 1751 he got the chair of Logic in the university of Glasgow, and this was changed a year afterwards for that of Moral Philosophy. In 1759 appeared his *Theory of Moral Sentiments*, celebrated for its reference of the mental emotions to the one source of sympathy. The *Dissertation on the Origin of Languages* was published along with the later editions of this book. Both had a great reputation in their day, and, although they are now obscure books in comparison with that other by which the author's name is remembered, the position they held with respectable thinkers gave a hearing to his doctrines on political economy which they would hardly have otherwise obtained. In 1762 the university of Glasgow gave him the degree of Doctor of Laws. In the following year he undertook a task, which might at first seem very uncongenial to a mind like his, given to retired study and independent thought and action—he became 'governor' or travelling tutor to the young Duke of Buccleuch. He was then sedulously collecting materials for his great work, and no doubt the inducement to accept the office was the opportunity it gave him for travelling and seeing for himself. He had the opportunity of being nearly a year in Paris, and of mixing in the circle of renowned wits and philosophers of the reign of Louis XV., including Quesnay, Turgot, and Necker. In 1766 his engagement came to an end, and he returned to Kirkcaldy to live in the old house with his mother.

The year 1776 was an era in the history of the world as well as that of the Kirkcaldy recluse, by reason of the appearance of the *Inquiry into the Nature and Causes of the Wealth of Nations*. If there was any living man to whose works he was indebted for the leading principles of this book it was David Hume, and it was from him, as best understanding the fullness and completeness of the exposition, that it had its first emphatic welcome. He wrote immediately on receiving it: 'Euge! Belle! Dear Mr Smith, I am much pleased with

your performance; and the perusal of it has taken me from a state of great anxiety. It was a work of so much expectation by yourself, by your friends, and by the public that I trembled for its appearance, but am now much relieved. Not but that the reading of it necessarily requires so much attention, and the public is disposed to give so little, that I shall still doubt, for some time, of its being at first very popular. But it has depth, and solidity, and acuteness, and is so much illustrated by curious facts that it must at last take the public attention.' This was not destined to be exactly the literary history of this great work. Its startling doctrines, fine clear style, and abundant illustration from curious facts took at first; but counteracting influences arose when people saw how far the new doctrines went in playing havoc with old prejudices. The French revolution set the mind of the country bigotedly against everything that breathed of innovation. It was known that the younger Pitt participated at first in Smith's free-trade notions, but he had afterwards, whether from permanent conviction or temporary policy, to put himself in the foremost ranks of the enemies of innovation. It was not until long after the terrors of that epoch and the nervous vicissitudes of the war had passed over that Smith's work had an opportunity of revolutionising the public mind on matters of trade and finance. It came up, as it were, the leader of a great literary host, for expounders long crowded in numbers round *The Wealth of Nations* as the text-book of sound economy. It has been made matter of reproach against this work that it is not systematic in its form and that its nomenclature is not exact. But its author was not arranging the results of established knowledge—he was rather pulling down existing structures, compounded of ignorance and prejudice. Nor, indeed, have those who have attempted to make an exact science out of political economy practically vindicated the reproach they have cast on him of being unmethodical. Whatever we may yet come to, very few portions indeed of political economy admit of being treated as exact science; it is too closely connected with human passions and energies, and consequently with special results and changes, to be so treated.

In 1776 he lost his friend David Hume. He watched by him on his death-bed, and wrote an account of his last illness and death in a memorable letter to Mr Strahan in London. Soon afterwards he established himself in London, and became a member of the club to which Reynolds, Garrick, and Johnson belonged, though with the last Smith's relations were not uniformly amicable. In 1778 he was made a Commissioner of Customs. The only effect of this was to bring him to Edinburgh, and increase his means for indulging in his favourite weakness, the collection of a fine library; for he was, as he called himself, a 'bean in his books.' He lost his worthy mother in 1784; in 1787 he was chosen Lord Rector of Glasgow University; and he died 17th July 1790.

Smith's position in the history of political economy, his relation to his predecessors, and his influence on later economists have been considered in the articles *POLITICAL ECONOMY*, *FREE TRADE*. It is a mistake to hold that the barren principle of *laissez-faire* was the teaching of Adam Smith. Smith held it to be the duty of the state to protect its citizens from infectious diseases, to endow by charter joint-stock companies with exclusive trading privileges, to enforce military training on all males, and to establish compulsory and cheap education; state intervention being, however, justified only where the work cannot be done by individuals, or not so well as by the state. Smith's works were edited in 5 vols. by Dugald Stewart in 1811–12, and contain, besides the *Theory of the Moral Sentiments* and the *Wealth of Nations*, essays on the first formation of languages, on the history of

astronomy, ancient physics, and ancient logic, and on the imitative arts. There have been numerous editions of the *Wealth of Nations*, by McCulloch (1850), Thorold Rogers (1880), Nicholson (1884), and Cannan (1904). His system has been dealt with by all subsequent economists, and in all civilised languages. His Glasgow lectures on *Justice, Police, Revenue and Arms* were published in 1897. See Lives by Dugald Stewart (1811), Farrer (1881), Hall-dane (1887), John Rae (1895), Macpherson (1899), and Hunt ('Men of Letters,' 1904).

Smith, ALBERT, was born at Chertsey, Surrey, on 24th May 1816, and educated at Merchant Taylors' School. He entered the Middlesex Hospital, and, after in 1838 becoming an M.R.C.S., proceeded to Paris to complete his studies. He then commenced practice with his father, but soon relinquished it for lecturing and light literature, and published upwards of a score of books, some of which were illustrated by Leech. His novels include *The Adventures of Mr Ledbury* (1844), *Scattergood Family* (1845), *Marchioness of Brin-rilliers* (1846), *Christopher Tadpole* (1848), and *The Pottleton Legacy* (1849); of his entertainments the most successful was 'The Ascent of Mont Blanc' (1852). He appeared in this at the Egyptian Hall only two days before his death, which took place at Fulham on 23d May 1860.

Smith, ALEXANDER, poet, was born 31st December 1830 at Kilmarnock, but brought up at Paisley and Glasgow, became a pattern-designer in a Glasgow warehouse, sending occasional verses to the *Glasgow Citizen*. Through George Gilfillan his *Life Drama* appeared in several issues of the *London Critic* (1851), and was reprinted the next year in a volume of which 10,000 copies sold in a very few months. But the author had scarcely found himself famous when he began to be fiercely assailed. The poem was certainly immature and extravagant, while an immoderate admiration of Keats and Tennyson coloured his expression, giving rise to the charge of plagiarism. Still, a richness and originality of imagery more than atone for defects of taste and knowledge. In 1854 he was appointed secretary to the university of Edinburgh, and next year produced *Sonnets on the War* in conjunction with Sydney Dobell (q.v.), his brother-poet in the 'Spasmodic' school. He afterwards wrote *City Poems* (1857); the Northumberland epic, *Edwin of Deira* (1861); and, in semi-poetic prose, *Dreamthorp: a Book of Essays* (1863); *A Summer in Skye* (1865); and *Alfred Hugart's Household* (1866), a simple and touching story of Scottish middle-class life. In 1857 he married Miss Flora Macdonald from Skye; and he died at Wardie, near Edinburgh, 8th January 1867.

See the Rev. T. Brisbane's *Early Years of Alexander Smith* (1869), and the Memoir by P. P. Alexander prefixed to his *Last Leaves* (1869).

Smith, GEORGE, Assyriologist, was born of humble parentage in London on 26th March 1840. While pursuing his trade of bank-note engraver he found means to study the cuneiform inscriptions in the British Museum, and through the kindly notice and assistance of Sir Henry Rawlinson and Dr Birch was in 1867 appointed an assistant in the department of antiquities in that museum. He helped the former to prepare the third volume of *Cuneiform Inscriptions* (1870), and through his skill as an interpreter of the Assyrian monumental writing not only was able to fix the dates of important events in the history of the East, but discovered the *Chaldean Account of the Deluge* (1872). He likewise furnished (1871) the key to the interpretation of the Cypriote character and script. In 1872 he was sent by the proprietors of the *Daily Telegraph* to

Nineveh in quest of discoveries; the collections he brought home were presented to the nation. The British Museum commissioned him (1873) to return and complete the excavations he had begun amongst the ruin-mounds of ancient Assyria, an account of which expedition, entitled *Assyrian Discoveries*, was published in 1875. Whilst on a third visit to the same regions he suddenly died at Aleppo, in Syria, on 19th August 1876. Besides the books quoted, he wrote *Annals of Assurbanipal* (1871), perhaps his most important publication; *History of Assyria* (1875); *Eponym Canon* (1875), a work on oriental chronology; *History of Babylon* (ed. Professor Sayce, 1877); *History of Sennacherib* (ed. Professor Sayce, 1878); and papers contributed to *Translations of Biblical Archaeology* and the first series of *Records of the Past*.

Smith, GOLDWIN, son of a Berkshire physician, was born at Reading, 13th August 1823. He received his education at Eton and Oxford, where he had a brilliant career, completed by a first-class in classics in 1845. In 1847 he was elected Fellow of University College, and in the same year he was called to the bar at Lincoln's Inn. He was nominated assistant-secretary to the first, and secretary to the second Oxford University Commission, and served on the Popular Education Commission in 1858. He was regius professor of History at Oxford from 1858 till 1866. During the American civil war he was a strenuous upholder of the North, writing several pamphlets in support of the Federal cause, and in 1864 lectured in the United States. In 1868 he was elected to the chair of English and Constitutional History in the Cornell University at Ithaca, New York. In 1871 he settled in Canada, where he became a conspicuous publicist. He edited the *Canadian Monthly*, 1872-74, and founded and for a time edited *The Week* and *The Bystander*, strongly advocating commercial union or complete reciprocity between Canada and the United States. He wrote much for periodicals, and contributed to this Encyclopædia. He died 8th June 1910. Among his works are *Irish History and Irish Character* (1861); *Lectures on the Study of History* (1861); *Rational Religion* (1861); *Empire* (1863); *The Civil War in America* (1866); *Three English Statesmen* (Pym, Hampden, and Cromwell, 1867; new ed. 1882); *A Short History of England* (1869); *The Political Destiny of Canada* (1879); *Cowper* (1880); *Lectures and Essays* (1881); *Jane Austen* (1890); *The United States* (1893); *Questions of the Day* (1894); &c. His *Reminiscences* (1910) and *Correspondence* (1913) were edited by A. Haultain, who also wrote a monograph (1913).

Smith, GRAFTON ELLIOT, anatomist and ethnologist, was born at Grafton, New South Wales, 15th August 1871, and educated at Sydney High School and University, and St John's College, Cambridge. He made a study of the mammalian brain, and after his appointment as professor of Anatomy at Cairo (1894) his attention was given to mummies and to the transmission of early civilisation. In 1909 he moved to the chair of anatomy in Manchester University, in 1919 to that in University College, London. In his *Migrations of Early Culture* (1915), *The Evolution of the Dragon* (1919), *Elephants and Ethnologists* (1924), and other works by him and by the school of which he is leader, a very elaborate structure of theory has been erected, world-wide customs hitherto ascribed to independent invention are traced to special originating conditions in Egypt and radiation from that centre.

Smith, HENRY JOHN STEPHEN, mathematician, was born in Dublin, November 2, 1826, and was educated at Rugby and Balliol College, Oxford.

taking a double-first in 1849. In 1861 he became Savilian professor of Geometry. He died February 3, 1883. He was the greatest authority of his day on the theory of numbers (see his *British Association Reports* from 1859 to 1865), and also wrote on elliptic functions and modern geometry. In 1881 the French Academy offered their 'Grand Prix' for a demonstration of certain theorems, ignorant of the fact that they had already been demonstrated fourteen years before by Smith, to whom accordingly the prize of 3000 francs was awarded, but not till a month after his death. He was a man of great versatility, geniality, soundness of judgment, and delicacy of humour.

Smith, JAMES and HORACE, authors of *The Rejected Addresses*, were the sons of an eminent London solicitor, and were born, the former on 10th February 1775, the latter on 31st December 1779. Both were educated at Cligwell in Essex. James succeeded his father as solicitor to the Board of Ordnance; Horace adopted the profession of a stockbroker, and realised a handsome fortune, on which he retired with his family to Brighton. Both were popular and accomplished men—James remarkable for his gaiety and conversational powers, and Horace—the wealthier of the two—distinguished for true liberality and benevolence. Both had written for the *Pic-nic* (1802), the *Monthly Mirror* (1807–10), &c., when the committee of management advertised for an address to be spoken at the opening of the new Drury Lane Theatre in 1812, and the brothers adopted a suggestion made to them, that they should write a series of supposed 'Rejected Addresses.' They accomplished the task in six weeks—James furnishing imitations of Wordsworth, Southey, Coleridge, Crabbe, Cobbett, &c., and Horace those of Scott, Byron (all but the first stanza), 'Monk' Lewis, Moore, W. T. Fitzgerald, and others. In point of talent the authors were about equally matched; for though James had the greatest number of successful imitations, the most felicitous of the whole is Horace's 'Tale of Drury Lane, by W.S.' ('I must have done this myself,' said Walter Scott, 'although I forget on what occasion.') It is a curious fact in literary history that the *Rejected Addresses* should themselves have suffered rejection, and that the copyright, offered originally to Murray for £20 and refused, was purchased by him for £131 in 1819, after the book had run through sixteen editions, and had brought its authors over £1000. James was afterwards an occasional contributor to the periodical literature of the day, and received £1000 for writing Charles Mathews' 'entertainments.' Horace between 1807 and 1845 produced more than a score of three-volume novels—*Brambletye House*, *Tor Hill*, &c. These are forgotten, but a new edition of his *Tin Trumpet* (1836) appeared in 1869, in which year also an *édition de luxe* of the *Rejected Addresses* was published at New York. Of Horace's *Poems* (2 vols. 1846) the best known is the 'Ode to an Egyptian Mummy.' James died in London on 24th December 1839, and Horace at Tunbridge Wells on 12th July 1849.

See PARODY; also vol. i. of Hayward's *Biographical Essays* (1858), Timbs's *Lives of the Wits and Humourists* (1862), and Beavan's *James and Horace Smith* (1899).

Smith, JOHN, one of the Cambridge Platonists, was born early in 1616, the son of a small farmer at Achurch, near Oundle, in Northamptonshire. At eighteen he entered Emmanuel College, Cambridge, as a sizar, had Whichcote for his tutor, graduated B.A. in 1640, but missed a fellowship in his own college, as another Northamptonshire man already held one. However, the Earl of Manchester's clearances at Queen's College opened up for him a fellowship there in June 1644. Here he

laboured with diligence as Hebrew lecturer, Censor Philosophicus, Greek Prelector, and became in 1650 Dean of the college and Catechist. But his feeble health gave way, and he died, after a long illness borne with saintly patience, 7th August 1652, and was buried in the college chapel. His funeral sermon was preached by Simon Patrick, who wrote long after in his *Autobiography*, 'Blessed be God for the good I got by him while he lived.' His *Select Discourses* was published in 1660, again in 1673, in 1821, and at the Cambridge press in 1859. A selection was edited by Lord Hailes in 1756.

Smith, CAPTAIN JOHN, adventurer and explorer, was born at Willoughby, Lincolnshire, in 1580, and was educated at the schools of Alford and Louth. On his father's death in 1596 he made up his mind to go to sea, but instead his guardian bound him apprentice to a merchant of Lynn. Business not being to his mind, he accompanied the second son of Lord Willoughby to France, and at Havre saw some soldiering under Henry IV. Next we find him in the Low Countries, whence he crossed to Scotland, returned to Willoughby, lived in a wood and studied Machiavelli and Marcus Amelius, and exercised himself on a good horse with lance and ring. As the Turks were at that time ravaging Hungary he made up his mind to join the Christian army, and was robbed by four adventurers in France on his way thither. He joined a half-merchant, half-pirate, and in coasting round Italy and the north of Africa they were enriched by the capture of a Venetian argosy. Next at Graz, in Styria, he entered the service of Ferdinand, Duke of Austria, under whom he greatly distinguished himself, and had some astonishing adventures. He was sold as a slave and marched to Adrianople, but escaped and travelled through Germany, France, Spain, and Morocco. After a sea-fight with two Spanish men-of-war he returned to England in 1604 enriched with 1000 ducats. In 1605 he joined the expedition of a London company to colonise Virginia. In April 1607 Jamestown was founded on the James River. On the way out Smith had been accused of conspiracy and narrowly escaped hanging, but in June 1607 he had his full liberty, and was admitted to the governing council. There was a desperate scarcity of food, and in endeavouring to find supplies, he fell into the hands of Powhatan, an Indian chief, and was only saved from being clubbed to death by the intervention of the Princess Pocahontas (q.v.). Smith was elected President of the colony in 1608, but returned to England disabled by an accident with gunpowder towards the end of 1609. During 1610–17 he was again in North Virginia; and he died in London, 21st June 1631. His works include *A True Relation of Occurrences in Virginia* (1608), *A Description of New England* (1616), *New England's Trials* (1620), *General History of Virginia* (1624), and *True Travels of Captain John Smith* (1630). Charles Deane in 1866 first raised doubts as to the veracity of the Pocahontas story. Arber, who carefully edited Smith in 1884, believed in him implicitly; but doubts were again raised by Henry Adams (1892). There are Lives by Scheibler (1782), Sparks (1834), Simms, Warner, Ashten, Bradley (1905), and Johnson (1915). See an edition of the *Works* with Arber's notes, Bradley's introduction, and Seccombe's bibliography (1910).

Smith, JOSEPH. See MORMONS.

Smith, ROBERT, whose name lives in the Smith's Prizes at Cambridge, was born in 1689, and was cousin to the mathematician Roger Cotes, whom he succeeded as Plumian professor of Astronomy at Cambridge in 1716. He succeeded Bentley

as master of Trinity College in 1742, published *Harmonia Mensurarum* (1722), *A Complete System of Optics* (1738), and *Harmonics, or the Philosophy of Musical Sounds* (1748), edited the *Lectures on Hydraulics and Pneumatics* of Cotes in 1737, and died at Cambridge in 1768.—The two Smith Prizes, now amounting to about £23 each, are, by a Grace of October 1833, awarded annually for the essays of greatest merit on any subject in mathematics or natural philosophy by recent B.A.'s. Holders have been Henry Martyn, J. Herschel, Whewell, Airy, Colenso, Stokes, Cayley, J. C. Adams, Lord Kelvin, Tait, and Clerk-Maxwell.

Smith, Sir Sidney. See SMITH (Sir William Sidney).

Smith, Sydney, wit and reformer, was born at Woodford, Essex, on 3d June 1771, the second in a family of four sons and one daughter. His father, Robert Smith (1739-1827), was a clever eccentric, who 'bought, altered, spoilt, and then sold about nineteen different places in England;' from his mother, Maria Olier (died 1802), the daughter of a French Huguenot, he derived all his finest qualities. After five years at Southampton, in 1782 he was sent to Winchester, where he rose to be captain of the school, and whence, having first spent six months at Mont Villiers in Normandy, in 1789 he proceeded to New College, Oxford. He duly obtained a fellowship, but of only £100 a year, and in 1794 was ordained to the Wiltshire curacy of Netheravon, near Amesbury. 'Mr Hicks-Beach,' he tells us, 'the squire, took a fancy to me, and requested me to go with his son to reside at Weimar; but Germany became the seat of war, and in stress of politics we put into Edinburgh, where I remained five years' (1798-1803). During this time he officiated in an Episcopal chapel there, and published *Six Sermons* (1800); married in 1800 a Miss Pybus of Cheam in Surrey; and in 1802, with Jeffrey, Horner, and Brougham, started the *Edinburgh Review* (q.v.), writing eighteen of the articles in the first four numbers. He next lived six years in London, and soon made his mark as a preacher, a lecturer at the Royal Institution on moral philosophy (1804-6), and a brilliant talker; but in 1809 'was suddenly caught up by the Archbishop of York, and transported to the living of Foston in Yorkshire, where there had not been a resident clergyman for 150 years,' but where he continued for twenty as 'village parson, village doctor, village comforter, village magistrate, and *Edinburgh* reviewer.' He farmed his glebe and built a parsonage, but was pinched in his means till in 1820 he came into £400 a year. In 1828 Lord Lyndhurst, the Tory chancellor, presented him to a prebend of Bristol, and next year enabled him to exchange Foston for the more desirable rectory of Combe-Florey in Somerset. In 1831 Earl Grey appointed him a canon residentiary of St Paul's, and this completed his round of ecclesiastical preferment. Visions of a mitre had sometimes crossed his waking dreams, but those dreams were never to be realised. However, he managed to 'grow old merrily' at Combe-Florey, which, in his own phrase, 'bound up well with London.' In London he died at his house, 56 Green Street, Grosvenor Square, on 22d February 1845. He is buried at Kensal Green.

Sydney Smith's writings include sixty-five articles, collected in 1839 from the *Edinburgh Review*, where they had appeared during 1802-27; *Peter Plymley's Letters* (1807-8), in favour of Catholic emancipation; *Three Letters to Archdeacon Singleton on the Ecclesiastical Commission* (1837-39); and various pamphlets on contemporary abuses and forgotten controversies, all consigned now to oblivion. So that their author is chiefly remem-

bered as the creator of 'Mrs Patington,' the kindly sensible humorist who stands immeasurably above Theodore Hook, if a good way below Charles Lamb.

His *Life* (1855) was written by his daughter Saba (1802-66), who in 1834 married Dr (Sir) Henry Holland (q.v.). See also Hayward's *Essays* (1858), Stuart J. Reid's *Life of him* (1884; new ed. 1896), Briscoe's *Wit and Wisdom of Sydney Smith* (1900), and G. W. E. Russell's *Sydney Smith* ('Men of Letters,' 1904).

Smith, Walter Chalmers, Scottish poet, was born in Aberdeen in 1824, studied at Olk Aberdeen and Edinburgh, and, after holding a Presbyterian charge in London for some years, laboured as a Free Church minister at Orwell (Kinross shire), in Edinburgh, in Glasgow, and again till 1894 in Edinburgh in the Free High Church. He died 19th September 1908. Widely popular as an admirable preacher, he won the favour of a yet larger public by a series of volumes of poetry marked by richness of thought, creative imagination, and lyrical charm, although unequal and not seldom careless in construction. These are *The Bishop's Walk*, by 'Orwell' (1861); *Olrig Grange*, by 'Hermann Kunst' (1872); *Hilda among the Broken Gods* (1878); *Raban, or Life Splinters* (1880); *North-Country Folk* (1883); *Kildrostan, a Dramatic Poem* (1884); *Thoughts and Fancies for Sunday Evenings* (1887); *A Heretic* (1890).

Smith, William, called the Father of English Geology, was born at Churchill in Oxfordshire, 23d March 1769. He became a land-surveyor and engineer, and so was naturally drawn to geology; and in 1794, after his appointment as engineer to the Somerset Coal Canal, he began his study of the strata of England. His epoch-making Geological Map of England was published in 1815, and from 1819 to 1824 he published, with self-denying zeal, no fewer than twenty-one geologically coloured maps of English counties, assisted in the latter task by his nephew and pupil, John Phillips, afterwards professor at Oxford. Smith received the LL.D. degree from Trinity College, Dublin, in 1835, and a pension of £100 from the crown in 1831. He died at Northampton, 28th August 1839. He was buried here, and thus had his wish to be buried in the Oolite as he had been born on it. See his *Memoirs* by Professor Phillips (1844), and T. Shepherd, *William Smith: his Maps and Memoirs* (1920).

Smith, Sir William, compiler and editor, born in London in 1813, distinguished himself highly in Greek and Latin in the examinations of the university of London, and went through the course of law at Gray's Inn. But he began the real work of his life in 1840 with the publication of editions of the *Apology*, *Phædo*, and *Crito*, of Plato, and the *Agricola*, *Germania*, and part of the *Annals* of Tacitus. His great *Dictionary of Greek and Roman Antiquities* appeared in 1840-42, and was only superseded by its own third edition in 1891 (2 vols.). The *Dictionary of Greek and Roman Biography and Mythology* (3 vols. 1843-49) followed, and this magnificent series of classical handbooks was concluded by the *Dictionary of Greek and Roman Geography* (2 vols. 1853-57). Their learned editor next turned, and with still more striking success, to the task of preparing a series of smaller classical dictionaries for schools; and some years later still achieved further successes with his well-known series, *Principia Latina* and *Initia Græca*, on a method extended also to German and Italian. Students' manuals of history formed the next series of books he put forth, including *Greece*, *Rome*, *France*, *Hume*, and *Hallam*. His complete edition of Gibbon's *Decline and Fall* appeared in 1854 (8 vols.); his serviceable *Latin-English Dictionary*

in 1855; the *Student's Latin Grammar* in 1863; the *Manual of English Literature* in 1864; and the *English-Latin Dictionary* in 1870.

Another monumental group of works is his series of theological dictionaries: the famous *Dictionary of the Bible* (3 vols. 1860-63; new ed. 1893); *A Dictionary of Christian Antiquities*, in conjunction with Archdeacon Cheetham (2 vols. 1875-80); and *A Dictionary of Christian Biography, Literature, Sects, and Doctrines during the first eight Centuries*, in conjunction with Dr Wace (4 vols. 1877-87). He became editor of the *Quarterly Review* in 1867, held the D.C.L. of Oxford (1870) and other honorary degrees, and was knighted in 1892. He died on the 7th October 1893.

Smith, WILLIAM HENRY, newsagent, book-seller, and Cabinet Minister, was born in London, June 24, 1825. He was educated at the grammar-school, Tavistock, and while a youth entered his father's business, and rose step by step to be head of the firm. This, the largest wholesale newspaper business of the kind in Britain, was founded by his father (born 1792), who saw that the London newspapers, sent off by the evening coaches only, were not delivered in Manchester and Liverpool until forty-eight hours after publication. He conceived the idea of forwarding the papers by express parcel, with private coaches leaving London in the morning, so that the night coaches were overtaken, and the delivery of news secured twenty-four hours in advance. As the business expanded, to this was added the right of selling books and newspapers at railway stations (Birmingham Railway, 1849). W. H. Smith was as strong in organising faculty as his father had been, and business was extended. He represented Westminster, 1868-85; was returned for the Strand in 1885 and again in 1886. He held the posts of Financial Secretary of the Treasury (1874-77), First Lord of the Admiralty (1877-80), Secretary of State for War (1885); in Lord Salisbury's ministry he was First Lord of the Treasury and leader of the House of Commons till his death, 6th October 1891. He left a large fortune, and his widow was raised to the peerage as Viscountess Hambleton. See his *Life* by Sir Herbert Maxwell (2 vols. 1893).

Smith, WILLIAM ROBERTSON, theologian and orientalist, was born at Keig, Aberdeenshire, on 8th November 1846. He received all his early training from his father, the Rev. William Pirie Smith, D.D., minister of the Free Church at Keig. He entered the university of Aberdeen in 1861, and graduated after an exceptionally brilliant career in 1865. He afterwards studied theology at the Free Church College, Edinburgh, at Bonn, and at Göttingen; while in Edinburgh he was also assistant to the professor of Physics (Professor P. G. Tait) in the university there. Immediately on the conclusion of his theological studies he was elected by the Free Church Assembly of 1870 to the vacant chair of Hebrew and Old Testament Exegesis in the Free Church College, Aberdeen; his suggestive inaugural address being *What History teaches us to seek in the Bible* (1870). At an early stage in the preparation of the ninth edition of the *Encyclopædia Britannica* he was invited to contribute articles upon Biblical subjects. The first of these ('Angel') appeared in 1875. That on 'Bible' (1875), a brief objective account of the now well-known historical and scientific facts of the subject, was almost immediately assailed on the ground of its heterodoxy—especially for its acceptance of the non-Mosaic authorship of Deuteronomy. In consequence of the excitement that had been aroused, the Assembly of 1876 referred all Smith's articles then published to a committee, which reported in 1877 that there was no ground

for a heresy prosecution, but added that a majority of the members of the committee had found cause for 'alarm' and 'anxiety' in the article 'Bible' on account of its 'dangerous and unsettling tendency.' In these circumstances a prosecution for heresy was instituted before the Free Presbytery of Aberdeen. A long process ensued, in the course of which Smith displayed remarkable debating talents, and in the end, after many vicissitudes in the various courts of the church, the trial resulted in the acquittal of the accused at the Assembly of 1880 by a majority of 7 in a house of nearly 600 members. In consequence, however, of the article on 'Hebrew Language and Literature,' which appeared in the *Ency. Brit.* in June 1880, he was not allowed to resume his teaching duties during the following winter; and although no new heresy was alleged to have been broached in that article, he was removed from his chair without a trial by a considerable majority at the Assembly of 1881. Smith, who, besides contributing largely to successive volumes of the *Encyclopædia Britannica*, had written several important pamphlets in connection with his trial, delivered at the request of a number of laymen in Edinburgh and Glasgow in 1880-81-82 two series of lectures substantially published in *The Old Testament in the Jewish Church* (1881) and *The Prophets of Israel* (1882). In 1881 Smith removed to Edinburgh, and became actively associated with Professor Baynes in the editorship of the *Ency. Brit.*; on the death of his colleague he had the undivided responsibility of editor-in-chief. In the beginning of 1883 he was appointed Lord Almoner's professor of Arabic in the university of Cambridge, where shortly afterwards he was elected to a fellowship at Christ's College. His work on *Kinship and Marriage in Early Arabia* was published in 1885. In 1886 he was elected by the Cambridge senate to the university librarianship, which office he exchanged for the Adams professorship of Arabic in 1889. As Burnett lecturer he delivered at Aberdeen in 1889-91 three courses on the religion of the Semites; the first series was published as the *Religion of the Semites* (1889). After several years of greatly impaired health, he died 31st March 1894. See *Life* by Black and Chrystal (1912).

Smith, SIR WILLIAM SIDNEY, the hero of Acre, was born at Westminster, 21st July 1764, entered the navy at eleven, and received a lieutenancy for his courage at Cape St Vincent in 1780. After further service under Graves and Rodney, he rose to the rank of captain in 1782; gave advice to the king of Sweden in the war with Russia (1790-92), being knighted as a reward; was next sent on a mission to Constantinople, and aided Hood in burning the ships and the arsenal at Toulon in December 1793. He next watched the Channel for French privateers, but was taken prisoner in Havre-de-Grâce harbour in April 1796. He succeeded in making his escape in 1798, and in October was sent as plenipotentiary to Constantinople, whence he hastened to St Jean d'Acre on hearing that Bonaparte was about to attack. On the 16th March 1799 he captured the enemy's vessels, and he held the town heroically until Napoleon raised the siege, leaving his artillery behind, on the 20th May. For this he received the thanks of parliament and a pension of £1000. Sir Sidney Smith next aided Abercromby in Egypt, became rear-admiral of the blue in 1805, and successively guarded Sicily and Naples, destroyed the Turkish fleet in Abydos (1807), blockaded the Tagus, became vice-admiral of the blue in 1810, K.C.B. in 1815, and admiral in 1821. He died at Paris, 26th May 1840. See the *Life* by Barrow (1848).

Smithfield, or **SMOOTHFIELD**, is an open space of 5½ acres in London, used for centuries as a

market for sheep, horses, cattle, and hay. Being a little north of Newgate and west of Aldersgate, it was outside the city walls, and available for jousts, tournaments, executions, and burnings. It was also a place of recreation for the people, and the celebrated Bartholomew Fair (q.v.) was held in Smithfield. Here the patriot Wallace was executed by Edward I.; here in the great agrarian revolt Wat Tyler, at the head of 30,000 peasants, encountered Richard II., and was stabbed by Walworth, the Mayor of London; and it was here that many of the long line of martyrs from 1401 to 1612 suffered in the flames or on the scaffold. With the growth of the city the cattle-market became an intolerable nuisance (described in *Oliver Twist*), and was finally closed in 1855. The Smithfield Club (1798) holds its annual cattle shows in the Agricultural Hall. Smithfield has still its hay market and a great meat market.

Smithfield, a village of Virginia, on a navigable creek 24 miles WNW. of Norfolk, contains in St Luke's Episcopal Church (1632; built of imported brick) the oldest Protestant building in America, and after the adobe cathedral at Santa Fé the oldest surviving Christian edifice in the United States.

Smithsonian Institution, at Washington, D.C., was organised by act of congress in 1846 in accordance with the will of James Macie Smithson (1765-1829), who, in a fit of pique at the Royal Society's rejection of a paper which he had submitted in 1826, bequeathed the reversion of an estate of £105,000 to the United States of America to found 'at Washington an establishment for the increase and diffusion of knowledge among men.' He was an Englishman, a natural son of Sir Hugh Smithson, first Duke of Northumberland, and Mrs Elizabeth Macie, a niece of Charles, Duke of Somerset. He devoted his life to scientific pursuits, especially to chemistry and mineralogy, was a Fellow of the Royal Society from 1787, and for long a member of the French Institute, and died in Genoa. The institution is a body of which the presiding officer *ex officio* is the president of the United States, and the Chief-justice of the United States customarily the chancellor. It is governed by a board of regents appointed by the Federal government, its direction under them being confided to a chief officer styled the Secretary. It has a spacious and beautiful building, forming one of the chief architectural adornments of the capital, which is occupied by offices and workrooms, but mainly by the collections of the government, which also fill separate adjoining buildings. In these buildings under its ownership or direction are the results of the exploring, surveying, geological, ethnological, and other expeditions of the Smithsonian and the government, known as the United States National Museum. The work of the institution is to promote original research; to publish the results of investigations, and distribute them freely to libraries in every land; to facilitate the interchange of scientific thought and labour, by sending and receiving free of cost the publications of all learned societies. It has a working library, but its main collections of books are in the Library of Congress (see LIBRARY). Its publications consist of a quarto series, *Smithsonian Contributions to Knowledge*, an octavo series, *Miscellaneous Collections*, both published at the expense of the fund, and an annual Report printed by congress. Under its direction are certain government bureaux: (1) the National Museum, (2) the National Gallery of Art (including the Freer Gallery), (3) the Bureau of Ethnology, (4) the Bureau of International Exchanges, (5) the National Zoological Park, (6) the Astro-physical Observatory, as well as the Regional

Bureau for the United States for the International Catalogue of Scientific Literature.

Smith's Sound. See BAFFIN BAY; also POLAR EXPLORATION, and map there.

Smock-frock, an outer garment of coarse white linen worn by agricultural labourers over their other clothes, especially in the south of England. It is like the French blouse, but longer; and the shoulders are often somewhat elaborately ornamented with neatly sewn folds and puckers.

Smoke, a common term to signify the volatile products of the imperfect combustion of such organic substances as wood or coal. The smoke from burning wood is almost colourless, consisting principally of carbonic acid and water, whilst that produced by burning coal is generally laden with oily and tarry vapour and finely divided carbon (or soot). The different effects resulting from the use of these varieties of fuel is exemplified in the brightness of Paris as compared with the (too generally) gloomy atmosphere of London. In London the smoke nuisance is an old grievance; Evelyn the diarist wrote his *Fumifugium* in 1661; and in his diary explains the unpleasantness of the great fog of the winter of 1684 (when a fair was held on the Thames), and justly ascribes it to the 'fuliginous steam of the sea-coale.'

The smoke nuisance may justly claim pre-eminence for itself in Great Britain, where coal is generally cheap, and where its users either from ignorance or prejudice refuse to adopt means for its proper combustion. In bright warm windy weather the smoke so produced is carried away from towns and factories, and becomes lost to view by mixing with the air; but in cold calm weather with an atmosphere saturated with moisture (or what is a true white fog) the smoke is arrested, and mixing with it gradually accumulates, and forming as it were a vast aerial emulsion of water vapour, tarry matter, and soot, gives rise to the black or brown fogs now so common in the large city. This dirt and soot suspended in the air not only causes disease by entering the lungs, but also acts as a screen obstructing the sunlight. But apparently what is most deleterious to plant life in towns and to human lungs is the sulphur in the coal, which so long as coal is consumed must be liberated by burning, and is ultimately oxidised into sulphurous and sulphuric acids. That the general death-rate in a town is enormously increased in foggy weather is indubitable; though, on the other hand, there is probably some disinfecting influence from the carbon and sulphurous acid present in a foggy atmosphere.

In this article there fall to be explained, first, the causation of such dark-coloured fogs; secondly, what has been done and what may yet be done in the direction of their prevention. (1) When a microscope slide is passed quickly over a smoky flame, a thin, semi-transparent film is left on the glass, which when examined under a powerful microscope presents the appearance of numerous particles of amorphous carbon in a finely divided condition, each particle being surrounded by an areola or coating of oily or tarry matter. This explains why a black fog may be and will remain persistent, even while rain is falling, each particle of carbon being, so to speak, surrounded by a waterproof coating which repels moisture. Aitken conclusively proved that the separation of liquid water from a moisture-laden atmosphere or white fog is due to particles of fine dust present in the air (see FOG). We should therefore expect that the introduction of solid particles of carbon into such an atmosphere would have the same effect, which doubtless would be the case did not each particle repel the vaporous particles of water in its

immediate neighbourhood; at the same time their density is insufficient to cause them to fall through the turgid atmosphere as smuts.

In a smoky town when a breeze prevails the smoke in its horizontal passage through the air gradually parts with its greasy-coated carbon to anything which impedes its progress, such as buildings, trees, &c.; so much so that only a few miles away it loses its dolorous aspect and assumes the soft, dreamy haze so dear to the painter, which after all is only an air emulsion of finely attenuated particles of grease.

The densest fog of this kind on being agitated will deposit all its carbon as smuts, and become changed into a white fog or mist; therefore changes of temperature causing convection currents, or electrical discharges, will disperse the densest fog with extraordinary rapidity. In like manner such a fog finding its way into a dwelling-house is exposed to currents of dry heated air, in which the condensed moisture reassumes its gaseous or invisible condition, while the other constituents are deposited as a grimy coating upon its walls, furniture, &c. Likewise in breathing such a fog-laden atmosphere the carbon and oily products are arrested by the air-passages, and become apparent in the expectorated secretion from the bronchial tubes. A comparatively small amount of solid carbon and oily vapour may thus bring about atmospheric conditions wholly at variance with all ideas of beauty, comfort, and cleanliness. Of course with perfect combustion only carbonic acid and water vapour are the products; both being colourless vapours. There are numerous mechanical stokers by which the green fuel is gradually carried from the furnace doors to the fire bridge, by which means the smoke and tarry vapours given off during the distillation stage are forced over the mass of incandescent fuel occupying the posterior position in the furnace. In some cases the fuel is also by mechanical means fed from the bottom of the grate bars, by which means the same end is gained. The only objection to the general use of such stokers is the expense of erection, and the cost of upkeep.

(2) *Smoke Abatement*.—It has been pointed out that wherever smoke is agitated—e.g. by atmospheric or electric currents—its carbon is quickly deposited by its particles agglomerating into masses too heavy to remain in suspension. This may be simply shown, as, when smoke is agitated by fanners or air-currents in a closed space, in a short time it loses its characteristic black colour, the carbon being deposited as smuts.

Other plans by which smoke from furnaces is passed through water and washed have been tried with more or less success, and may come to be compulsorily adopted in factories, as is now the case with iron blast-furnaces, where the products—viz. carbon, hydrocarbons, ammonia, and even the carbonic and sulphurous acids present in all coal-smoke—are profitably utilised. By means of such appliances there is now no difficulty in preventing the emission of coloured smoke from any factory-chimney. But the real difficulty which meets all attempts at smoke abatement lies in the sentimental desire for the cheerful though smoky blaze of English house-fires. This causes, it has been estimated, in London alone the production of thousands of tons of black smuts per annum, which descend either on the city itself or in its immediate vicinity.

Long ago it was pointed out that to obtain the full advantage of the use of coal it should be carbonised—i.e. heated in closed retorts, when the whole of the volatile products, consisting of oil, tar, and gas, would be properly utilised, leaving a coke which would not only burn with a smokeless flame, but give out, weight for weight, a much

larger amount of available heat than the uncarbonised coal. At the same time the inflammable gas (one of the products of this process) would either alone or mixed with the coke yield, when properly burned, a smokeless fuel for use in kitchens or fireplaces, thus doing away with this serious evil, as well as effecting an annual saving of many millions of tons of coal.

Many attempts have been made to effect this by constructing house-gates and cooking ranges so that the raw coal is introduced from the bottom—i.e. at the fire-bars or grids, so that all gaseous products have to pass through an incandescent mass of carbon before reaching the chimney. The mechanical difficulties to be overcome would necessitate the entire reconstruction of the present house-heating arrangements. But a good deal has been done to abate the smoke nuisance from domestic chimneys by the growing use of smokeless fuel, by gas-cookers, and similar heating apparatus. For the *Method of Zones*, see HOUSING AND TOWN-PLANNING. The Public Health Act of 1875 condemns 'any chimney (not being the chimney of a private dwelling-house) sending forth black smoke in such a quantity as to be a nuisance,' while the Act of 1926 is more comprehensive, at the same time increasing the penalties.

See books on Smoke Abatement by Booth and Kershaw (1904), Nicholson (1906), Cohen and Ranton (1925); a Bibliography by McClelland (1913); and Fitzgerald, *The Smokeless City* (1922); also the publications of the London Coal Smoke Abatement Society, and Smoke Abatement League of Great Britain; the latter holds frequent conferences on the subject. In Germany corresponding societies and the government educate stokers in the scientific management of firing, and stimulate and test the ingenuity of inventors of smoke averting appliances. See also FUEL.—For a special use of smoke, see HAM, PRESERVED PROVISIONS. For Smoker's Sore Throat, see TOBACCO. For Opium-smoking, see OPIUM. For Smokeless Powder, see GUN-COTTON, GUN-POWDER, RIFLES.

Smoky Mountain. See APPALACHIANS.

Smolensk, a city of Russia, stands on steep declivities overlooking the river Dnieper, 244 miles W. by S. of Moscow. It was a place of note in the 9th century, has a cathedral of the 17th and 18th centuries, a university (1919), some fine buildings, and was from the 14th century a powerful fortress, and as such an object of contention between the princes of Lithuania and Poland on the one side and of Moscow on the other. Here the Russians were repulsed by Napoleon, 17th August 1812. Pop. 60,000.

Smollett, TOBIAS GEORGE, physician, poet, novelist, journalist, historian, was a Dumbartonshire gentleman, belonging to that upper class of Scottish society—the lawyers and landed gentry—to which Sir Walter Scott also belonged. He was educated for the medical profession, but failed to make a living by it. He drifted into literature, and by it he made a precarious living and a lasting name. For the failure of his life in material success he was himself largely to blame. Handsome, upright, generous, of genuine humour, a pleasant companion on occasions, he yielded from his youth to (among other mischievous propensities) the evil habit of epigrammatic sarcasm on one or other of the company he was in. Proud, vindictive, of hot temper and haughty manner, as sensitive as he was satirical, he was a foreordained failure as a doctor, and foredoomed to quarrels, lawsuits, fine and imprisonment, and money difficulties in general as a journalist. The little poetry he wrote was not of great merit. His history was, as David Hume estimated it, a clever superficial review of the subject. It was the novels that made his name, and three of them maintain it.

Smollett was grandson of Sir James Smollett of Bonhill, advocate, member of the Scottish parliament, commissioner of the treaty of Union, and judge in the consistorial court. The fourth son of Sir James and his first wife, daughter of Aulay Macaulay of Ardencape, was Archibald, who, without his father's sanction and without means to support a wife, married Barbara, daughter of Robert Cunningham of Gilbertfield, a young lady of good family but portionless. Sir James assigned to the imprudent couple Dalquhurn, the second house on the estate, and the few fields around it, on which stand now the towns of Alexandria and Renton. The third child of Archibald and Barbara was Tobias George, born at Dalquhurn, birthday not recorded, baptised on Sunday, March 19, 1721. His father died shortly after, and his grandfather in 1731. Sir James and his successor would seem to have behaved with reasonable kindness to the widow, a clever managing woman, and her three orphan children. Smollett went to Dumbarton grammar-school, was taught Latin well by John Love, and distinguished himself by the luxuriance of his boyish satire. He went to Glasgow College, attended arts and medical classes, and while attending them served an apprenticeship to John Gordon, doctor, apothecary, and very worthy man. It was thus he qualified for medical practice. Subsequently, in June 1750, he obtained the degree of M.D. from Marischal College, Aberdeen. In 1739 he went to London and tried to get *The Regicide, a Tragedy*, put on the stage. He failed, quarrelled with everybody about it, and published it ten years later with a very foolish preface. He romances about the ill-usage he and it underwent in the story of Melopoyne in *Roderick Random*. Smollett was appointed surgeon's mate on board the *Cumberland*, which sailed in 1740 to join Admiral Vernon's fleet, and took part in the unfortunate expedition to Carthagena in 1741. He describes that expedition in *Roderick Random*, and also in a *Compendium of Voyages and Travels* he published in 1756. His temper could not brook the service; he quitted it in the West Indies and tarried a while in Jamaica, where he met Anne Lascelles, the expectant heiress of 'a comfortable, though moderate, estate in the island.' Mr Buck sees good reason to believe that he married her before he left the island. Others date his marriage 1747. He seems to have returned to London in 1742 or 1743. In 1744 he set up house in Downing Street, afterwards in Mayfair, to look for medical practice. He wrote *The Tears of Scotland* in a coffee-house in 1746. The same year appeared *Advice, a Satire*—his first publication. Next year he published *Reproof, a Satire*. *The Adventures of Roderick Random*, written autobiographically, appeared anonymously in 1748, and was at once a great success; Lady Mary Wortley Montagu thought the novel was Fielding's. *The Regicide* was published in 1749. In 1750 Smollett visited Paris along with Mr Moore—afterwards Dr Moore, novelist, father of Sir John Moore—and met Mark Akenside there. In 1751 was published, written biographically, *The Adventures of Peregrine Pickle*. It too had an instant success. The doctor, who gives an entertainment after the manner of the ancients, is a misrepresentation of Dr Akenside, and the laughable account of the feast is a satire on his pedantic affectation of Athenian manners. Smollett was paid for inserting 'The Memoirs of a Lady of Quality, Frances Hawes, Lady Vane,' which are a blot on the novel. He now tried to set up in Bath as a medical man, publishing *An Essay on the External Use of Water*; it was his last attempt of the kind, and it failed. Returning to London to live by his pen, he fixed his abode in Chelsea, and published *The Adventures of Ferdinand, Count Fathom* in 1753.

The robber scene in the Black Forest, from that story of a gambler and swindler, has been the prototype of many such, and is a literary masterpiece. About this time an action was raised in the Court of King's Bench against Smollett for causing a person named Gordon. The verdict was in his favour, but the law-costs embarrassed him. In 1755 his translation of *Don Quixote*, which is still read, was favourably received. He became in 1756 editor of *The Critical Review*, a High Church and Tory monthly. Countless troubles to the editor culminated in 1759, when Admiral Knowles brought an action against the *Review*, and Smollett was fined £100 and sent for three months to the King's Bench Prison. In 1756 he also began a *Complete History of England* from the time of Julius Cæsar's invasion down to 1748. He wrote the four quarto volumes in fourteen months, finishing the work in December 1757. This effort brought on chest disease and a scorbutic affection; he never enjoyed good health again. After coming out of prison he wrote a continuation of his History, which he eventually brought down to 1765. From all this labour on history he is 'said to have cleared £2000.' In 1757 his farce, *Reprisals, or the Tars of Old England*, was put on the stage by Garrick. Smollett toiled at compiling a universal history and translating Voltaire. *The Adventures of Sir Lancelot Greaves*, an English Don Quixote, appeared as a serial, 1760-61, in the *British Magazine*, a sixpenny monthly, and was published separately in 1762. Like all the novels Smollett wrote, it is weak in construction, but lacks neither vivacity nor wit. He edited *The Briton*, 1762-63, a weekly paper in support of Lord Bute's administration, received no reward, and was routed from the newspaper field by the *North Briton*, the organ of his former friend, John Wilkes. In April 1763 Elizabeth, his only child, died of consumption. He left England in June, sojourned on the Continent more than two years, and published in 1766 the still readable *Travels through France and Italy*. The same year he, broken in health, visited Scotland—his second visit since he left as a lad—and while in Edinburgh stayed with his mother and widowed sister. His health benefited by this journey, but on his return south it broke down again. He left England in 1768 to seek recovery in a warmer climate. He had the year before solicited a consulship at Nice or Leghorn—the only favour he ever asked from government—was refused it, and went to live in Italy, relying on his wife's small and always uncertain income and on his pen. He wrote the *Ode to Independence* about this time. *The History of the Adventures of an Atom*, a prose satire, in which political leaders are broadly caricatured under fictitious names, was published in 1769. In a village, called Monte Novo, near Leghorn, Smollett wrote, in weakness and much pain, the last and best of his novels, *The Expedition of Humphry Clinker*, written in epistolary form. The 'Ode to Leven Water' occurs in it. It was published in 1771; and Smollett just lived to hear the first rumours of its success. He died, 17th September 1771, aged fifty-one, and was buried in the English cemetery, Leghorn. If he had lived four years longer he would have inherited the family estates; as it happened, he left his widow quite unprovided for. Her small income from the West Indies by and by failed entirely, and there was a benefit performance in the Theatre Royal of Edinburgh in her behalf when she was destitute twelve years after his death. The novels which have become classics are the three in which Smollett himself is adumbrated as, respectively, the Scottish Roderick Random, the English Peregrine Pickle, and the Welsh Matthew Bramble (*Humphry Clinker*).

Plays and Poems, with Memoir (1 vol. 12mo. 1784). *Miscellaneous Works*, first collected by David Ramsay of the *Edinburgh Evening Courant*, humorous frontispieces by Howlandson; meagre life (6 vols. 8vo. Edin. 1790; does not contain *Adventures of an Atom*). *Miscellaneous Works, with Memoir*, by Robert Anderson, M.D., carefully edited (6 vols. 8vo Glasgow, 1796); *Expedition to Carthage* added to 2d edition (6th ed. 1820) *Works, with Memoir*, by John Moore, M.D. (8 vols. 8vo. Lond. 1797), carelessly edited; memoir valuable owing to personal intimacy. *Miscellaneous Works, with Memoir*, by Thos. Roscoe (1 vol. large 8vo. Lond. 1840). Sir W. Scott's Biographical Prefaces, published separately (2 vols. 12mo. Paris, 1825). *Life and Selections*, by Robert Chambers, (1867). *Works*, carefully selected—the three classical novels, the plays, the poems—with *Life and Notes* by David Herbert; *Notes* fill up blanks left by Smollett (1877). *Works*, ed. Henley and Seacombe (12 vols. 1899–1901). *Novels* (Shakespeare Head edition, 11 vols. 1925 et seq.). *Works*, ed. Santsbury (12 vols. 1925). *Letters*, ed. E. S. Noyes (1926). See also Hazlitt's *Comic Writers*; Thackeray's *Humourists*; Seacombe in the *D.N.B.* (1898); *Lives* by Hannay (1887), Smeaton (1897), Melville (1926); and (especially for *Peregrine Pickle* and Smollett's quarrels) *A Study in Smollett* by H. S. Buck (1925).

Smolt, a name given to young river salmon when they are bluish along the upper half of the body and silvery along the sides.

Smuggling, a violation of customs laws, to be distinguished from illicit distillation, which violates excise laws (see CUSTOMS DUTIES, EXCISE), no longer deserves the name of a trade in the United Kingdom. From about the close of the 17th century to near the middle of the 19th the suppression of that kind of free trade by vigorous methods engaged the close attention of the inland revenue department. Free trade as a national policy put down the smuggling trade. Only a very small number of persons comparatively deal in contraband goods now. But when the duties on spirits were higher in England than in Scotland, Northumberland and Cumberland were haunted with smugglers. Haddington and Berwick and the Scottish counties on the Solway were long demoralised by unwise tariffs on articles of import from abroad. Readers of Scott's novels know the effective use he makes of smuggling for the purposes of his art in *Guy Mannering* and *Redgauntlet*. Robert Burns was an exciseman, and it was also one of his duties to prevent the smuggling of contraband goods. It is well known how in 1792 he placed himself on one occasion at the head of the revenue officers and a guard of dragoons, waded the Solway sword in hand, was the first to board a smuggling brig, captured the crew, and had the brig sold at Dumfries. It was on that occasion that Burns wrote 'The Deil's awa' wi' the Exciseman.' The exploits of smugglers and coastguardsmen in the frequent and bloody encounters that took place constitute the main interest of many an exciting tale.

The contrabandista used to be one of the most popular characters in Spain. The exports from England to Gibraltar, to refer only to one of his lines of activity, used to be large, and were introduced by smugglers to the interior of Spain. The injudicious tariffs imposed by both England and France encouraged smuggling to an enormous extent on both sides of the English Channel: spirits, especially brandy, tea, tobacco, silk goods from France; from England the most important article of illicit trade was cotton-twist. English goods were introduced into France chiefly by the Belgian frontier, and dogs were trained to convey them; a dog would convey goods worth from £20 to £50. There used to be cruel slaughter of these dogs, a reward of three francs being given by the customs authorities for every one seized.

A great historical outburst of smuggling was the answer which commercial enterprise gave to Napoleon's Berlin and Milan decrees. Silk from Italy reached England by Smyrna after being a year on passage, by Archangel after being two years. Cotton-twist, coffee, sugar, tobacco were shipped from England to Salonika, conveyed thence by mules and horses through Serbia and Hungary to Vienna, and distributed over the Continent from that capital. Coffee from London would reach Calais by Vienna. The risks and expense raised the price of sugar on the Continent to 6s. a pound.

In 1831 an official report estimated the loss by smuggling to the British revenue as exceeding £800,000 a year (in French brandy to the extent of £500,000). Three-fourths of the tobacco consumed in Ireland was smuggled; the total annual cost of protecting the revenue was then from £700,000 to £800,000. In 1840 it was believed that 48 per cent. of French silks paid no duty. The south coast of England, especially Kent and Sussex, was largely addicted to the smuggling trade with France, by which it was stated that goods to the value of £2,000,000 were conveyed into France from England by the Belgian frontier alone.

So long as the Isle of Man had an independent system of customs (till 1765) it proved a veritable focus of 'smuggling' with adjoining British coasts, especially the north shore of the Solway Firth, where the whole population became demoralised by the 'free trade.' The smaller lairds connived at it, or shared in it; the Rev. Robert Carson, parish minister of Anwoth (successor of the sainted Samuel Rutherford), was deposed because he not only smuggled himself, but encouraged others to smuggle. 'Brandy-holes' were found in the most unlikely places. One subterranean chamber might be discovered and ransacked, with small result, by the revenue officers, while a rich store was concealed in a chamber directly beneath the other, but so hermetically sealed as to escape the observation of lynx-eyed 'gaugers.' Sets of underground chambers connected by various tortuous passages were not unusual; and the entrance to such vaults was sometimes under the hearthstone of a humble (and pious) cottager, or might be cunningly concealed beneath the fireplace of a mill-kiln, and inaccessible so long as the fire was burning. Alan Fairford's adventures in *Redgauntlet* are wonderfully true to fact.

Among the principal articles liable to duty in the United Kingdom are cocoa, coffee, currants, raisins, beer, spirits, wine, tea, tobacco; and the sugar duty encourages some smuggling of saccharine. The law is mainly regulated by Customs Acts of 1876, 1879, 1881, and the Merchant Shipping Act of 1894. The number of seizures of smuggled goods averages at present some 8000 per annum, tobacco being the principal article. A curious source of evading customs duties was at one time found to be common in the navy, tobacco-stalks being landed contrary to law. Tobacco being issued to the crews of H.M. ships of the navy in the form of unmanufactured leaf, the men could, in preparing it for use, remove the mid-rib of the leaf, which they are enjoined by regulations to destroy; the landing of the stalk, formed by the mid-rib when separated from the leaf, is, of course, prohibited by law. But the stalks being serviceable for making snuff, a considerable trade existed in certain localities, with the intervention of the receivers, between seamen and others employed on board H.M. ships and persons who purchased stalks for the purpose of obtaining drawback upon the snuff produced from them.

Smuggled goods are liable to forfeiture, and are sold for revenue purposes. Vessels engaging in

smuggling are liable to forfeiture, and their masters and owners to a penalty up to £500. Fraudulent evasion of customs duties, or attempted evasion, renders the offender subject to forfeit treble the value of the goods, or a money penalty of £100. Heavy penalties are incurred by resistance to customs officers, or aiding and abetting smuggling. In the United States the penalties are similar, but in some cases severer; a sailor guilty of smuggling is liable to a penalty, as in England, and to imprisonment for twelve months in addition.

See W. D. Chester, *Chronicles of the Customs Department* (1885); Lieut. H. N. Shore, *Smuggling Days and Smuggling Ways* (1892); also the article TAX.

Smut, or **BUNT** (sometimes also called **Dust-brand**), is the popular name of certain small fungi which infest flowering land-plants, especially the grasses. This name is derived from the appearance of the spores, which are nearly black and very numerous. At the present time the group is called the *Ustilagineae*. Some of them live in the intercellular spaces only, others penetrate the walls of the cells, especially of the parenchyma (simple) cells, and live within the living matter of the plant. Some species attack a part only of their host—e.g. *Entyloma* forms pustules on the leaves of certain species of *Ranunculus*; others spread throughout the tissues, forming spores in special places. Thus the mycelium of *Tilletia tritici*, which causes the disease specially known as **Bunt** in wheat, may spread through the whole of a wheat-plant, but the spores are found only in the ovary. Various species of *Ustilago* fructify in the inflorescences of various grasses, and cause the disease known as **Smut**. The part of the plant where the fructification is being formed is generally enlarged, and becomes filled with the black resting spores. This swelling is especially noticeable in maize-plants attacked by *U. zeae*. The mycelial hyphae are not very densely spread within the tissues of a host, but the hyphae that will bear spores branch repeatedly, and thus form a mass of compact tissue within that part of the host selected for the fructification, this compact mass taking the form of that part of the host, or covering with a flat layer a part of the surface, or eating a cavity out of the tissues of the plant and taking the form of that cavity. Generally the spore-bearing hyphae become transformed into spores, so that nothing but spores remains, but some species form definite envelopes for the spores—e.g. *Doassansia*. The germination of the spores occurs when they have been well saturated with water. Typically, a germ tube is emitted which is called the promycelium. This, in most cases, gives forth from the far end a number (4 to 10) of smaller tubes, called sporidia. From these sporidia there may arise a tube which takes all the protoplasm; this tube, called an incipient mycelium, may enter into the tissues of a host and develop a true mycelium. Sometimes in a species which usually develops in this way any or all of these steps may be omitted—e.g. the spore may give rise to an incipient mycelium direct. Important economic diseases of this type in Britain are the smuts of oats and barley and smut and bunt in wheat. The last, also known as stinking smut from the characteristic fishy odour of the spores, is best dealt with by pickling the seed in dilute formaldehyde or by treating it with finely powdered copper carbonate. See **WHEAT**. The other diseases are combated by soaking the seed in hot water.

See **FUNGI**; also Bennett, *Outlines of Fungi and Plant Diseases* (1924), &c.

Smuts, JAN CHRISTIAN, statesman and general, was born at Pretoria in 1870, was student at Christ's College, Cambridge, and practised at the Cape Town Bar. He was given supreme command

of the Boer troops in the Cape Colony (1901), but in 1916-17 commanded the British forces in East Africa. He had held many political posts, and had represented South Africa in the Imperial War Cabinet (1917-18) and at the Peace Conference (1919), before becoming premier of the Union (1919-24), succeeding Botha, whose right-hand man he had always been. He was an ardent supporter of the League of Nations. His philosophical studies bore fruit in a volume on *Holism* (1926), tracing in the universe a progressive organisation in greater and greater wholes.

Smyrna, the most important seaport of Asia Minor, stands on the west coast, at the head of the Gulf of Smyrna, which penetrates 46 miles inland from the Aegean Sea; it climbs up the slopes and nestles at the foot of Mount Pagus (460 feet, on the south-east), which is crowned by the ruins of the ancient Greek Acropolis. Viewed from the waters of the Gulf it presents a fine appearance, but the great fire of 1922, beginning in the Armenian quarter and spreading to the Greek and then to the Frankish or European (which included the banks, consulates, hotels, &c. on the quays), left untouched only the miserable Turkish quarter on the higher slopes. About three-fifths of the town was destroyed, with great loss of human life. Previously there were a great number of modern mosques, churches, bazaars, &c., but few buildings with any architectural pretensions, and the city was the seat of archbishops of the Roman Catholic, Greek, and Armenian churches, and of the Turkish governor-general of the province (*vilayet*) of Aidin. Traces of the ancient walls, the stadium, theatre, and some temples can still be discerned. Rebuilding has progressed but slowly, owing to the uncertain political situation, the flight and deportation of so many of the former inhabitants, the new scheme of planning which involves much greater space for streets, public squares, gardens, &c., the consequent difficulties of expropriation and compensation, and the lack of sound financial backing. *Bariakli* and *Cordelio* are two modern suburbs on the north shore of the Gulf. The climate is uncertain, but intensely hot in summer, and earthquakes are by no means unknown, those of 178 A.D., 1688, 1768, and 1880 having been particularly severe. Smyrna is well served with three main lines (with branches) of railway, ensuring direct communication with *Panderma* on the Sea of Marmora, *Angora*, and *Damascus*. But it is as a commercial seaport that the place is specially celebrated. It still remains the great entrepôt for Asia Minor that it was seven hundred years before Christ. The harbour is large, safe, and easily accessible. It is the centre for all the important trade of the interior, in corn, raisins, figs, valonia, tobacco, wool, skins, oil, and silk, all of which are exported, and the surrounding country is rich in minerals—chrome ore, lignite, salt, mercury, iron, zinc, and antimony. The industries, however, were badly affected by the looting and massacres which accompanied the fighting after the Great War and the fire of 1922. Carpets, cotton, silk, and soap factories, tanneries, iron, saw and flour mills were formerly largely in the hands of Armenians or Greeks, who were deported in enormous numbers after the Treaty of Lausanne (1923), when a compulsory exchange was arranged between Greeks of Turkey (excluding Constantinople) and Mohammedans of Greece (excluding Western Thrace). Pop. estimates (1900) 250,000; (1914) 350,000, of whom one-half were Greeks; (1924) 100,000.

Smyrna was originally a city of the Greek *Æolic* immigrants into Asia Minor, and was one of the seven cities associated with Homer; it became Ionian, and during the 7th century B.C. enjoyed wonderful prosperity as the principal intermediary

in trade between Enope (Greece) and Lydia; but at the end of the century it was captured and destroyed by Alyattes, king of Lydia. For more than three hundred years it maintained merely a struggling existence; but it was at length rebuilt on a different site by Antigonus, and further enlarged and fortified by Lysimachus, both inheritors of the conquests of Alexander the Great. Under the Romans its commercial fame was revived, though it had rivals in Ephesus and Peigamum, and at a later date a still more formidable rival in Byzantium, to whose emperors it belonged. It became famous, too, as an ecclesiastical centre, and was one of the Seven Churches of the Apocalypse: St Polycarp, its second bishop, suffered martyrdom there in 155 A.D., and an archbishopric was created in the 6th century. Smyrna was frequently sacked by the Turks, was partly occupied by the Knights of Rhodes (1344), destroyed by Tamerlane (1402), and finally captured by the Turks under Murad II. in 1424. The 17th and 19th centuries also witnessed a great commercial prosperity, nearly ruined, however, by the Balkan Wars (1912-13), the Great War, and succeeding events. In May 1919 the Greeks occupied Smyrna and the surrounding *vilayet* in virtue of the Treaty of Sévres. To counteract Italian designs in South Anatolia they began next year their advance into the interior, at first successful. The Turks, however, by a supreme effort under Kemal Pasha (q.v.) drove the Greeks from the country, and entered Smyrna, 9th September 1922. Four days later the great fire occurred. War between Turkey (q.v.) and the Allied Powers was only narrowly averted.

Smyth, DAME ETHEL, was born at London in 1888, and studied music at Leipzig Conservatorium. Her chief compositions include two symphonies, a Mass (1893), and the operas *Der Wald* (1901), *The Wreckers* (1906), *The Boatwain's Mate* (1916), *Fête Galante* (1923), and *Entente Cordiale* (1925). At times influences of classical composers, especially Brahms, are apparent, but as a whole her works are full of sincere, vigorous writing. Recognition of her worth came first from Germany. She was a militant suffragist, published excellent volumes of reminiscences in 1919 and 1921, and in 1922 was created a D.B.E.

Snail, a term employed to designate the species of terrestrial Gasteropoda (q.v.) which have well-formed spiral shells. The more typical snails

Fig. 1.—Common Snail (*Helix aspersa*): a, eggs; b, appearance when newly hatched; c, slightly advanced stage; d, mature snail.

belong to the genus *Helix*, of the family *Helicidae*, and have the shell of many whorls, globose, depressed, or conical. The aperture or mouth of the shell is more or less encroached upon by the last whorl but one, it is often strengthened by an internal thickened rib, its edges are usually more or less reflexed, and there are sometimes calcareous

tooth-like prominences known as the denticles or apertural lamellae. The animal progresses upon a foot or sole, which is flattened beneath, and fringed at the edge. There are four retractile tentacles, the two upper ones the largest, and bearing the eyes. There is a crescent-shaped jaw, which is usually strongly ribbed. The tongue or lingual membrane bears very many teeth arranged in transverse rows. Thus, the Common Garden Snail has 135 rows of 105 teeth=14,175 in all. Snails are hermaphrodite, but mutual insemination takes place. They are provided with calcareous styles or darts, which are secreted within a sac, the dart-sac, from which they are protruded during copulation. The forms of these darts are very various, and sometimes offer excellent characters for the separation of allied species. The eggs of snails are round or oval, and are deposited in damp places or in the earth. Those of the Edible Snail are nearly as large as a pea. At the approach of winter, or in very dry weather, snails close the mouth of the shell with a membrane (*epiphragm*) formed by the drying of the mucous substance which they secrete, and become inactive and torpid. Some, as the Edible Snail, make a succession of such membranes, the outer one of which is also strengthened by a quantity of calcareous matter, the secretion being at first a white

Fig. 2.

Snails:
a, *Helix aspersa*;
b, *Helix arbustorum*

viscid fluid, but quickly hardening like plaster of Paris. When this is to be removed a fresh secretion of fluid mucus softens it at the edges. The Common Garden Snail is to some extent gregarious when in the torpid state: many individuals may frequently be found closely packed together in cracks in walls, under logs or stones, and in other sheltered places. Snails delight in warm moist weather, and are active chiefly at night and during or after rain. They are also more abundant on limestone soils than elsewhere; the kinds found in districts where there is little or no lime have frequently very thin shells, owing to the deficiency of calcareous matter to strengthen them. Snails feed chiefly on vegetable substances, although they are very indiscriminate in their appetite, and even devour the dead of their own kind. The mischief which they do to garden crops is too well known; and gardeners are constantly on the alert to destroy them. Thrushes and blackbirds devour great quantities of snails; they select a suitable stone against which they break the shells. These 'breaking-stones' may often be found in fields and by roadsides surrounded by fragments of shells. Snails possess in a very high degree the power of repairing injuries, and specimens may not rarely be found in which part of the shell has been broken and repaired again. Snails are found in nearly every part of the globe, some thousands of species having been described by authors. Seventy species are found in the British Islands, of which twenty-two belong to the genus *Helix*. The Edible or Roman Snail (*H. pomatia*), much esteemed as an article of food on the Continent, is regularly bred on large and prosperous snail-farms in canton Zurich, Bavaria, and elsewhere, being fed on salad, greens, kitchen-waste, meal, &c. It is a large tawny species, not rare in parts of the south of England (especially Kent and Surrey), and is sold for food in London. The Common Garden Snail (*H. aspersa*), the most destructive species in Britain, is too abundant in most places, but rare in parts of Scotland and north-west England. It is also used for culinary purposes, notably in the Newcastle, Bristol, and Swindon districts. The Striped Snail (*H. nemoralis*) is smaller than the Garden Snail,

and of various colours, usually red or yellow, ornamented with one to five spiral dark-brown bands. The rim or lip of the aperture in this species is dark brown, but in a closely allied species, *H. hortensis*, it is white. Both these species are very common, and it is a favourite custom for collectors to obtain large series showing the variation, their beauty and interest being very great. Taking variations in the banding alone, already eighty-nine of *H. nemoralis* and fifty of *H. hortensis* have been found within the British Islands, while very many others are known from abroad. *H. nemoralis*, when introduced into Virginia, produced many band-variations which are not known in Europe. *H. arbustorum* is a species about the same size as *H. nemoralis*, but brown, mottled with pale yellowish, and usually encircled by a single dark band. The Kentish Snail (*H. cantiana*) is smaller, whitish, more or less tinged with rufous. The Hairy Snail (*H. hispida*) is a small horn-coloured or brown species found in hedges, among moss, &c.; its shell is clothed with minute hairs or bristles. *H. virgata* is a species rather over $\frac{1}{2}$ -inch in diameter, found very abundantly in chalky places, on downs, and by the sea. It is usually white with one or more dark-brown bands, though some of the varieties are blackish or yellowish. On the South Downs this and an allied but smaller species (*H. cuperata*) are so abundant that the sheep, when feeding upon the short grass, can scarcely avoid devouring them; and the excellency of the South Down and Dartmoor mutton has in part been attributed to the nutritive qualities of the snails. *H. ericetorum* is another species allied to *H. virgata*, and found in similar places, but it is larger and has the shell much flattened above. *H. pulchella* is a minute but very beautiful species, found abundantly both in Europe and North America. Hyalinia (often called Zonites) is a genus of small snails in which the jaw is without ribs, and the shell smooth and shiny. There are eleven British species. Some of them emit a garlic odour, especially *H. alliaria*. *H. crystallina* is a small species of a clear white colour. The genus Pupa consists of brown cylindrical shells, resembling small seeds. Some of them, which are placed in the sub-genus Vertigo, are exceedingly minute. *P. antiverugo* has the aperture of the shell so barred by long calcareous processes (denticles) that it is a wonder how the animal can emerge from it. Clausilia is somewhat similar to Pupa, but longer both actually and in proportion to the width; the aperture is turned to the left (*sinistral*) instead of to the right (as is the case with the majority of snails), and is provided with a very curious spiral, shelly plate (*clausium*). A south European snail (*Stenogyra decollata*) is of a cylindrical shape, and sheds its upper whorls when it becomes adult, the aperture so formed being covered by a shelly plate. Adult specimens thus appear truncate, presenting a very singular appearance.

Snake Bird. See DARTER, WRY-NECK.

Snake Cult, Snake Dance. See SERPENT-WORSHIP.

Snake River, the largest affluent of the Columbia River, rises among the Rocky Mountains near the western border of Wyoming, sweeps in a rough semicircle through southern Idaho, forming here the famous Shoshone Falls (q.v.), and, turning north, divides Idaho from Oregon and partly from Washington. At Lewiston it turns westward, and in southern Washington, under the name of the Lewis River or Fork, joins the Columbia, after a course of some 1050 miles. It traverses a very mountainous country, flowing through deep, lava-walled cañons, and is navigable for steamboats

only to Lewiston (160 miles). Its chief affluents are the Boisé, Owyhee, Malheur, Salmon, Clearwater, and Palouse.

Snake-root. See BISTORT, MILKWORT, ARISTOLOCHIA, and SENECA.

Snakes (*Ophidia*) form one of the classes of reptiles, and are readily known by their shape, being limbless and much elongated. To some extent the shape may be an adaptation to the habit of creeping through crevices and among dense herbage; for, apart from snakes, it is seen in other animals which crawl through obstacles or underground, in limbless lizards (e.g. *Amphibæna* and *Anguis*), in the amphibian *Cæcilians*, in various eel-like fishes, and in worms.

General Habit and Structure.—As regards habitat we distinguish tree-snakes, usually green in colour, of slender body, and of active habits; the water-snakes, including the non-poisonous freshwater forms, such as the British Grass Snake and the tropical Anaconda, and the very venomous sea-snakes (*Hydrophidæ*), whose flattened tail, apical nostrils, &c. are adaptations to their mode of life; the burrowing snakes (*Typhlopidae*), with rigid cylindrical bodies, narrow mouths, and no specialised ventral shields; and the majority, which may be called ground-snakes.

The scales covering the body are formed from folds of skin. In each species of snake they have a definite arrangement, which is greatly relied on in the more detailed classification. This is especially true of the shields on the head, which are usually named after the underlying bones—parietals, frontals, nasals, &c.; thus between the nasal scale (on which the nostril opens) and the pre-orbital (in front of the eye) there is in harmless snakes a loreal scale, which is one of their characteristics. Most important in the life of the animal are the strong ventral scales or shields, for each of these is attached to a pair of ribs and helps to grip the ground. As they correspond in number to the vertebrae, they are also diagnostic of species. The number of vertebrae in snakes is often great, in some pythons amounting to more than four hundred. They form a uniform series, distinguishable only into pre-caudals and caudals, and all the pre-caudals except the first bear ribs. The bodies of the vertebrae are concave in front and have well-developed articular processes.

The skull is highly specialised. The bones which form the brain-case proper are firmly united, but most of the others are movable. Thus, 'when the snake opens its mouth for the purpose of striking its prey, the digastric muscle, pulling up the angle of the mandible, at the same time thrusts the distal end of the quadrate bone forward. This necessitates the pushing forward of the pterygoid, the result of which is twofold: firstly, the bending of the pterygo-palatine joint; secondly, the partial rotation of the maxillary upon its lachrymal joint, the hinder end of the maxillary being thrust downward and forward. In virtue of this rotation of the maxillary, through about a quarter of a circle, the dentigerous face of the maxilla looks downward, and even a little forward, instead of backward, and the fangs are erected in a vertical position' (Huxley). The halves of the lower jaw are connected in front by an elastic ligament, and this, combined with the mobility of the quadrates and squamosals, makes it possible for the snake to swallow its relatively large prey.

The teeth of snakes are short, conical, and sharp, and are fused to the bones which bear them. The upper teeth may occur on the maxillæ, palatines, pterygoids, and rarely on the pre-maxillæ; the lower teeth are borne as usual by the dentaries.

In the most venomous snakes, such as vipers and rattlesnakes, the maxillary teeth are few, and each is folded so as to form a tubular or grooved fang. The specialised fang is connected by a gradual series of forms with the ordinary teeth.

As to the appendicular skeleton, no snake has any trace of anterior limbs or girdle, and only a few—the pythons, boas, Typhlopidae, and Tortrices—have any rudiment of a pelvis. The pythons and Tortrices have short rudiments of hind-limbs terminated by claws.

While the nervous system of snakes differs from that of other reptiles only in small details, such as the absence of a differentiated spinal accessory or eleventh cranial nerve, the sense-organs are in many respects peculiar. The upper and lower eyelid, vestigial in the embryo, remain undeveloped, but a transparent screen, probably due to the 'third eyelid' or nictitating membrane, is fixed across the eye and covered by a single transparent scale. The eyes are often small and the sight is often dim. As the common simile 'as deaf as an adder' suggests, the sense of hearing is also dull; there is no external ear and no tympanic cavity. The nostrils lie at the apex of the snout; the sense of smell seems sufficiently acute to guide the snakes to their prey and to their mates. In finding the latter they are aided by the peculiar, sometimes musk-like odour characteristic of snakes. Of a sense of taste they have little need, for they swallow their prey whole, nor are the usual gustatory organs present. It is not too much to say that the most developed sense-organ is the tactile tongue, with which snakes feel their way and test everything which they touch.

The internal structure of snakes presents several peculiarities in adaptation to the elongated shape of the body. Thus, the stomach is long but not broad, the lobes of the liver are also elongated, there is in most cases only one lung, the kidneys are not opposite one another, and so on. The elasticity of the food-canal is an adaptation to the swallowing of relatively large booty, and during this often slow process the larynx is shunted forward into the mouth so that respiration is not seriously impeded. Although boas, rattlesnakes, and some others have paired lungs, most snakes have only one, usually with a rudiment of the other. There are often auxiliary air-sacs on the windpipe, and the posterior part of the lung is rather a reservoir for air than an actual breathing organ. Apart from the characteristic hiss, produced by the forcible expulsion of air, most snakes are dumb, but some boas are said to whine, and a few others make peculiar sounds, of which the rattling of the rattlesnakes is best known. In having a three-chambered heart and a circulation of mixed blood in the greater part of the body snakes resemble lizards and tortoises. No urinary bladder is developed.

The Poison-apparatus.—The poison-gland characteristic of the venomous snakes is not a new structure, but merely a specialised salivary gland, and it is interesting to notice that a similar modification occurs in the poisonous Mexican lizard *Heloderma*. From the gland, which lies on each side behind the eye, and is about the size of an almond in the cobra, a duct extends to the base of the fang, down which the venomous juice flows when the snake bites its victim. The fangs are folded teeth, each an open groove, as in the sea-snakes, or a closed tube, as in the vipers. It is of course clearly to be understood that the 'sting of the serpent' is a poisonous bite. Stretching over the poison-gland is the membranous origin of the masseter muscle which works the lower jaw, and by means of this and other somewhat complex arrangements the poison-gland is automatically compressed when the snake opens its mouth to

strike. But the opening of the mouth also brings about the erection of the fangs, which are

Fig. 1.

Open mouth of a venomous snake, showing the fangs half-hidden in their sheaths. (After Nuhn.)

recumbent and ensheathed when not in use. Behind each functional fang is a series of reserve fangs, and if a fang be broken the foremost of the reserves is shunted forward, and becoming fixed to the maxilla replaces the one which has been lost.

The juice formed in the specialised glands and forced out along the fangs is a clear viscid fluid with an acid reaction, and with poisonous properties which vary according to the species

Fig. 2.

Dissection showing the poison-gland, *a*; its duct, *b*, the tubular fang, *c*, *d*; the reserve fangs, *e*. (After Nuhn.)

and also with the vigour of the snake. It may be kept for months or even years without losing its virulence. Injected through the fangs into the blood of a victim, it tends to paralyse the nerve-centres. It has most effect on birds and mammals, less on cold-blooded animals, such as fishes. An injection of the blood of a venomous snake may also prove fatal. Several venomous snakes are unaffected by their own venom, and Fayer states that Cobras and Daboias may bite one another with impunity. He also notices that the 'sweepers and Dhomes' who attended his elaborate experiments in India were wont to eat the animals which had been fatally bitten. In 1843 Lucien Bonaparte discovered in the poison of the adder (*Pelias berus*) a substance which he called 'vipérine', but this seems practically identical with the Ptyaline of ordinary saliva, and we are still far from understanding why the juice of the poison-gland should have its peculiar properties.

Food.—Snakes are almost always carnivorous; and, as is suggested by the nature of their teeth, which are not adapted for mastication, they swallow their booty intact. Mammals, birds, reptiles, amphibians, fishes, molluscs, and insects are all eaten by snakes, and there are many forms with strange preferences—e.g. for milk and eggs. In the egg-eating African snake—*Rachiodon*—the teeth are rudimentary, but the inferior spines of the anterior vertebra project on the dorsal wall of the gullet and break the egg-shells. In many cases the prey is relatively large—larger indeed than the normal size of the mouth and gullet—and the process of swallowing is tedious. In the python, for instance, there is a slow continuous action of jaws and teeth; the victim is firmly held by one side of the mouth while the other side is protruded and its teeth implanted further forward, and so on alternately on each side. Meanwhile the mobile bones of the skull are being stretched to the utmost, and the

victim is covered with saliva which makes the passage down the elastic gullet somewhat easier. After a heavy meal the snake often lies dormant for a time, after which it may cast its slough.

Movements.—Owen has said of snakes that they can 'outclimb the monkey, outswim the fish, outleap the zebra, outwrestle the athlete, and crush the tiger;' yet all without limbs. The muscular system is very strongly developed, and the long ribs associated with most of the vertebrae serve instead of legs. The serpent 'literally rows on the earth, with every scale for an oar; it bites the dust with the ridges of its body.' On a very smooth surface—on glass, for instance—it can make no headway, but in normal conditions the edges of the anterior ventral scales are fixed against the roughnesses of the ground, the ribs are drawn together first on one side then on the other, the body is thus wriggled forward to the place of attachment, the hind part fixes itself, the front part shoots out, an anterior attachment is again effected, and thus the snake glides onwards. But this scarcely suggests the swiftness or the beauty of what Ruskin calls 'one soundless, causeless march of sequent rings, and spectral procession of spotted dust, with dissolution in its fangs, dislocation in its coils. Startle it; the winding stream will become a twisted arrow; the wave of poisoned life will lash through the grass like a cast lance.' Were it not for many fanciful pictures it would scarcely be necessary to say that without any support snakes are not able to raise the anterior part of their body more than a short distance from the ground.

Sloughing.—It is well known that a snake periodically 'casts its skin,' leaving behind it a continuous 'slough.' The same process occurs in lizards, and to a less extent in some other animals. What is cast is the external layer of the epidermis, and its continuity depends on the fact that the scales are simply folds of skin. As to the physiology of the process, although a complete explanation has not yet been given, it is evident that the outer layer of the skin tends to die away, and that the continued growth of the animal makes sloughing necessary. The number of sloughings in a year varies with the species of snake and also with the age and health of the individual. Cobras have been observed to slough as often as once a month, but this seems to be unusually often. Before sloughing snakes are often almost blinded by the change in the skin over the eyes, and at this time they are said to be very irritable. In getting rid of its slough the snake gets its head free first, and the outer layer is turned inside out from before backwards.

Reproduction.—The sexes are almost always quite like one another externally, save that the females are always larger. The internal organs of reproduction are paired, but those of the right side are often the larger and lie in front of those on the left. The male has a double copulatory organ, sometimes covered with spines or hooks. The eggs, fertilised within the oviducts, are more or less oblong in shape, and are surrounded by a leathery envelope, 'for the rupture of which the embryos are provided with an egg-tooth, a special development like that of the chick.' Most snakes are oviparous, but, as among lizards, viviparous forms occur, such as the British Adder (*Pelias* or *Vipera berus*). It is said that Geoffroy Saint-Hilaire and Florent Prévost 'succeeded in making the (normally oviparous) Common Grass Snake viviparous by depriving it of water and maintaining a suitable surrounding temperature;' and it may be that some viperine snakes and the *Boa Constrictor*, which have borne their young alive in captivity, are oviparous in natural conditions of life. Of the python it is recorded that the mother coils herself around the laid eggs

and broods over them, the temperature within the coils rising as high as 96° F.

Classification.—Snakes may be thus classified—

SUB-ORDER I.—Opoterodontia (=Typhlopidae): the simplest and smallest snakes, sometimes smaller than earthworms, occurring in most warm countries as burrowers in the soil. The mouth is narrow and not distensible; the eyes are small and half-hidden; and the skull, besides being much less mobile in its parts than is usual in snakes, is unique in having transverse palatine bones which meet or nearly meet in the base, in the absence of a 'transverse bone,' and in the freedom of the pterygoids from the quadrate; only one jaw, either the upper or the lower, bears teeth. They are not venomous. Most of the forms belong to the genus *Typhlops*—represented in America, Africa, India, Australia, and by one species in south-eastern Europe.

SUB-ORDER II.—Colubritornia: mostly harmless snakes without any fangs (Acyphodontia), or with some of the posterior maxillary teeth grooved and fang-like (Opisthoglypha). Examples: the Pythons (Pythonidae), the Boas (Boidae), the Grass or Ringed Snake (*Tropidonotus natrix*), the Smooth Snake (*Coronella levis*), the Tree-snakes (Dendrophidae and Dryophidae).

SUB-ORDER III.—Colubritornia venenosi: poisonous snakes with permanently erect fangs, succeeded by solid teeth (Proteroglypha). Examples: Cobras (*Naja*), Hamadryas (Ophiophagus), Coral-snakes (Elaps), Sea-snakes (Hydrophidae).

SUB-ORDER IV.—Viperiformes: poisonous snakes, with a few erectile maxillary teeth specialised as fangs (Solenoglypha). Examples: Vipers (Viperidae) and Rattlesnakes (Crotalidae).

Distribution.—The number of species is certainly above 1000 and is sometimes estimated at about 1800. They are represented in most parts of the world, abundantly in the tropics, commonly in temperate countries, dwindling towards the poles. They are absent from New Zealand and most Oceanic islands, and it is a proverbial saying that 'there are no snakes in Iceland.' In Ireland also they are unrepresented, except by casual importations.

The Grass or Ringed Snake (*Tropidonotus natrix*) and the poisonous Viper or Adder (*Pelias* or *Vipera berus*) are the two common kinds of snake found in Britain. There is indeed only one other species, the Smooth Snake (*Coronella levis*), and this is of rare occurrence. The smooth snake and the ringed snake are non-poisonous Colubrine snakes; the viper is a small representative of a very venomous family. As the viper is discussed in a separate article, and as the smooth snake is restricted to a few parts of the south of England, we need only describe the ringed snake. It sometimes attains a length of 3 or 4 feet, is very fond of water, and feeds chiefly on frogs, small fish, young birds, mice, and other small animals. Its colours are beautiful—usually brownish gray with a green tinge above, dull pale bluish beneath. In summer it is fond of basking among the long grass; in winter it hibernates in some sheltered nook in company with several of its fellows. Unlike the adder, the ringed snake is oviparous, laying 16-20 eggs in some well-sunned spot. It is common in some parts of Britain. These three species also form the Ophidian fauna of Scandinavia, Denmark, Holland, and Belgium; but there are over a dozen other European species, of which one of the commonest is the Asp (*Vipera aspis*).

The North American Ophidia include a large number of Colubrine snakes and about a score of pit-vipers or rattlesnakes. Among the Colubrine forms are the water-snakes (*Tropidonotus*), the black snakes and coachwhip snakes of the genus *Coluber*, the pine-snakes (*Ptyopsis*), species of *Elaphis*, the king-snakes (*Ophibolus*), the ring-necked snakes (*Diadophis*), and so on. Besides the rattlesnakes proper (*Crotalus*) there are related genera, such as *Ancistrodon*, the copperheads and moccasins. And outside the two families of Colubridae and Crotalidae there are representatives of the burrowing Typhlopidae, of the boa-like Erycidae, and of the venomous coral-snakes (Elapidae)—the harlequin snake (*Elaps fulvus*) being a well-known representative of the last.

The Colubridæ form the largest and most cosmopolitan of Ophidian families, being abundantly represented in all the great regions except Australia, where the venomous Elapidæ predominate. 'The tree-snakes proper (Dendrophidæ) are found in all the tropical regions; the nocturnal tree-snakes (Dipsadidæ) and the arboreal whip-snakes (Dryophididæ) are also essentially tropical, but they are either wholly, or almost wholly, wanting in Australia' (Heilprin).

The Pythons and Boas are distinctively tropical snakes: the Pythons in Africa, India, Malaya, Australia; the Boas in tropical America. Among the most important venomous snakes of India are the following: the Cobra (*Naja tripudians*), the Hamadryas or Sunkerkhor (*Ophiophagus elaps*), the Krait (*Bungarus ceruleus*), and the Sanku (*B. fuscatus*), various species of Callophis, the Chain Viper or 'Bora Siah Chunder' (*Daboia russellii*), *Echis carinata*, various species of *Trimeresurus*, and the sea-snakes (*Hydrophis*, &c.).

Zoological Position.—It may be granted that snakes are more nearly allied to lizards than to other living reptiles, but the affinities are not close, nor does palæontology help us much, for fossil remains of Ophidia are scarce. 'Only one species, the *Simoliophis rochebruni*, from the Upper Cretaceous deposits of the Charente, France, is known to antedate the Tertiary period.' 'Whether or not the snakes are in part the modified descendants of the extinct lacertilian Pythonomorphs, to which they seem to approximate in certain points of structure, still remains to be determined.'

Superstitions about Snakes.—As snakes fill most men with fear, which is the prolific mother of fiction, hundreds of strange superstitions surround these animals. Born from the soil, they lick the dust for their food; powerful indeed, they are killed by spiders, and cannot stand before crabs; venomous many of them, they are poisoned by human saliva, and flee from the shadow of the ash or the odour of rosemary; their maximum size has been stated at a mile. It is not surprising that many peoples should have found in the serpent 'a divine hieroglyph of the demoniac power of the earth—of the entire earthly nature,' or even a symbol of the principle of evil. 'As the bird,' Ruskin says, 'is the clothed power of the air, so this is the clothed power of the dust; as the bird is the symbol of the spirit of life, so this of the grasp and sting of death.' For serpent worship, see SERPENTS.

We cannot wonder that the ingenuity of despair should have sought out many strange antidotes to the poison of serpents. Various kinds of herbs, portions of the snake's own body, a diet of 'antipathetic' animals, spells, charms, and amulets have been often resorted to, often of course with successful results, for the bite is not always fatal, and confidence is the best of tonics; often of course uselessly when the Fates were cruel. Among the most famous, and for the most part quite useless, 'cures' for snake-bite is the application of a 'snake-stone.' Although the nature of this so-called 'stone' is sometimes kept secret by the native quacks who prepare it, the substance is often a piece of charred bone, and its only possible efficacy lies in its power of absorbing the poisoned blood from the wound to which it is applied. But the results of actual experiments with snake-stones are entirely against any belief in their virtue. Some of the Ammonites (q.v.) have been used as snake-stones, the idea being that they were petrified snakes. Another kind of snake-stone or *adder-stone*, also called *ovum anguinum*, *adder-gem*, and *druidical bead*, was carried about as a miscellaneous charm in Britain, and was believed to have been produced by a number of adders laying their heads together

and hissing till the foam produced was turned into stone. Such charms when examined have often been found to be simply ancient—possibly prehistoric—spindle-whorls. See also BEZOAR.

As a superstition we must also regard the widespread belief that snakes 'fascinate' their prey. Although many observers are convinced of this, the use of the word 'fascinate' has not been justified. No doubt snakes, having no movable eyelids, have an unusual power of steady staring; no doubt birds whose nestlings are threatened will flit anxiously about regardless of danger. In countries where venomous snakes are common, it is possible that the animals on which they prey have an inherited dread of them. It is certain that both men and animals when brought suddenly face to face with something terrible are often panic-stricken and incapable of motion; but there is no evidence that snakes have a power of fascination.

Scarcely a superstition, but rather an insufficiently confirmed opinion, is expressed in the common belief that snakes swallow their young ones when danger threatens. Were not errors of observation exceedingly common, we should be inclined to accept this strange fact, for the shelter afforded by the mouth is a convenient if somewhat hazardous one, and the young snakes might live there for some time. It is known that a few fishes and amphibians carry their young in their mouths. But the possibilities of mistake are many: thus, some snakes eat other snakes, and their bodies have often been found in the food-canals of their larger neighbours. Moreover, some snakes are viviparous, and unpractised observers might mistake the oviducts for the alimentary canal.

Serpent-charming.—This art has been practised from very ancient times in Africa and the East, and often remains from generation to generation the profession of a family. Pliny and older writers frequently describe it, and there are several allusions to it in the Old Testament Scriptures; see Exod. vii. 11, 12; Psalm lviii. 4, 5; Eccles. x. 11; Jer. viii. 17. It is sometimes practised for alleged useful purposes, since the 'charm'ers' are often employed to clear a house of its unwelcome snake visitors, though common report says that they are yet more successful in removing inanimate objects. For the most part, however, it is, like conjuring, a form of popular amusement. In India it is practised by several distinct classes of men, who vary in the methods and success of their art. The subject has not as yet been studied with adequate scientific precision, so that it is difficult to separate what is due to trickery and to dexterity from any residual facts which cannot be thus explained. There is no reason to believe that the charm'ers possess the constitutional immunity from snake-bite which they often claim, for a tragic end to their exhibitions sometimes belies their pretensions, and they usually take good care to play with snakes whose fangs or even poison-glands have been carefully removed, or even to use those which are not venomous at all. Nor can we, without further evidence, believe that the professional snake-finders have, beyond the cleverness of long experience (including an educated sense of smell), any peculiar power of discovering concealed snakes, especially since it is well known that they often use simple sleight of hand, producing snakes from within the folds of their robes, or merely discover what they themselves have previously hidden. The frequent use of a musical pipe, and the way in which the snakes seem to respond to the sounds, are facts interesting to naturalists, who believe that at least many snakes are very deaf. Experiments should be made to determine how far the rhythmical motions which often accompany the

music may have any influence on the snakes. That the charmers govern their snakes by their eye is another of the vague assertions of common report; but more interesting is the ancient habit of spitting down the snake's throat, closing its mouth, laying it flat on the ground, and sending it into a cataleptic—perhaps hypnotic—state, or 'turning it into a stick.' The charmers sometimes manifest a fearlessly confident dexterity in handling intact venomous snakes, and they sometimes suffer for it.

Snake-bites.—The effect of a snake-bite depends, on the one hand, on the species of snake, on its vigour at the time, on the extent to which the teeth closed on the flesh of the victim, and so on; on the other hand, on the species and vigour of the organism bitten. In connection with the effects of different snake-poisons Dr A. H. Hilson divides venomous snakes into two classes: in the first, including the Cobra, Krait, Daboia, and other Indian snakes, the poisoning causes paralysis of the lower extremities and the muscles of articulation, is associated with a regular or intermitting action of the heart, with paralysis of the respiratory muscles, with persistent consciousness, with little effect on the sensory ganglia, and is unaffected by injection of ammonia into the veins; in the second class, including the common Australian poisonous snakes, the Rattlesnake, and the Indian genus *Trimeresurus*, the poisoning causes no paralysis or only as an adventitious symptom, is associated with failure of the heart's action, but with no impeding of respiration, with rapid obliteration of consciousness, with disordered sensory functions, and is curable by injection of ammonia into the veins and by the use of stimulants. Snake-poison is usually regarded as (a) a neurotic paralysing the nerve-centres, (b) an irritant producing inflammation, and (c) to some extent a septic. It acts through the circulation on the nerve-centres, and also affects the blood itself.

Fayrer summarises the treatment of snake-bite as follows: 'Apply at once a ligature, or ligatures at intervals of a few inches, as tight as you can possibly tie them; and tighten the one nearest to the wound by twisting it with a stick or other such agent. Scarify the wound, and let it bleed freely. Apply either a hot iron or live coal, or explode some gunpowder on the part; or apply either carbolic or some mineral acid, or caustic. Let the patient suck the wound whilst you are getting the cautery ready; or if any one else will run the risk, let him do it.

* If the bite be on a toe or finger, especially if the snake has been recognised as a deadly one, either completely excise, or immediately amputate at the next joint. If the bite be on another part, where a ligature cannot be applied, or, indeed, if it be on the limbs above the toes or fingers, cut the part out at once completely.

'Let the patient be quiet. Do not fatigue him by exertion. When, or even before, symptoms of poisoning make their appearance, give the ammoniacal preparation called eau-de-luë, or liquor ammonia, or carbonate of ammonia, or even better than these, hot spirits and water. There is no occasion to intoxicate the person, but give it freely, and at frequent intervals. If he become low apply sinapisms and hot bottles, galvanism or electro-magnetism over the heart and diaphragm. Cold douches may also be useful. If the respiration be failing, artificial Respiration [q.v.] . . . may be employed.

'The antidotes, in addition, may be used by those who have faith in them; but, as I have said, I fear there is no reason to believe that they are of any use. Encourage and cheer the patient as much as possible. As to local effects, if there be great pain, anodynes may be applied or administered, and antiseptic poultices to remove sloughs; collections of matter must be opened. Other symptoms

are to be treated on general surgical principles. This, I believe, is the sum and substance of what we can do in snake-bite. If the person be not thoroughly poisoned we may help him to recover. If he be badly bitten by one of the more deadly snakes we can do no more.'

By many reliance has been placed as antidotes on ammonia, permanganate of potash, arsenic, iodine, bromine, the poison and bile of other snakes, the guaco plant, ipecacuanha, aristolochia, senega. Fitzsimons (1912) recommends rubbing permanganate of potash into the well-opened wound. Most antidotes, he says, are worthless; ammonia and nicotine are actually dangerous. The ligaturing to be effective should be applied at once; and the permanganate of potash treatment should be followed by the injection of one of the generalised anti-venomous serums.

Uses of Snakes.—Some snakes—e.g. *Ophiophagus*—eat one another; many help to keep down the numbers of small animals, such as rats and mice, whose increase is disadvantageous. Several are used for food; the poison is sometimes used by native physicians as a medicine—'a promoter of the virtue of other drugs, an anti-spasmodic, a digestive, a stimulant,' &c.; it is also used to increase the deadliness of weapons. The oil extracted from the abundant fat of many snakes is said to be very useful for external application, and there is hardly a part of the body from which it has not been employed in superstitious therapeutics.

See ANACONDA, BOA, COBRA, PYTHON, RATTLESNAKE, VIPER, &c.; Hoffmann's 'Reptilia' in Bronn's *Thierreich* (Leip. and Heidelberg, 1859 et seq.); Duméril and Bibron, *Erpétologie Générale* (9 vols. Paris, 1834-54); Günther, *Reptiles of British India* (Lond. 1861); Blanford, *Fauna of British India* (1891); Fayrer, *Thanatophidia of India* (1874); Bell, *British Reptiles* (1839); Boulenger and others, *Catalogue of the Snakes in the British Museum* (3 vols. 1882-96); Jan and Sordello, *Iconographie des Ophidiens* (Paris, 1860-80); Krefft, *The Snakes of Australia* (Sydney, 1869); books on North American reptiles by Halbrook (1842), Baird and Girard (1853), Cope (1900), and Gadow (1906), and Hopley's *Snakes* (a popular work, 1882); and Leighton's *Life-History of British Serpents* (1901).

Snakewood. See BREAD-NUT.

Snapdragon (*Antirrhinum*), a genus of Scrophulariaceæ, consisting of annual and perennial herbaceous plants, chiefly natives of the temperate parts of the northern hemisphere. They have the calyx five-parted; the corolla swollen at the base, but without a spur, and *personate* (Lat. *persona*, 'a mask')—i.e. its mouth closed by the pressure of the lower against the upper lip; and the fruit is a two-celled oblique capsule, opening by three pores at the apex. The English name refers to a peculiarity of the corolla, the lower lip of which, if forcibly parted from the upper so as to open the mouth, shuts with an elastic spring or snap. Some of the species have very pretty flowers. *A. majus* has long been a favourite in British gardens, in which there are many fine varieties of it. The whole plant is bitter. An oil is extracted in Persia from the very abundant seeds,

Snapdragon (*Antirrhinum majus*).

by heating and then submitting them to pressure. —Snapdragon is also the name for a Christmas pastime in which raisins are snatched out of a dish in which brandy is burning, in a room otherwise dark.

Snaphaunce, a term originally applied to the spring-lock of a gun or pistol, but afterwards applied to the gun itself, a Dutch firelock of the 17th century. See FIREARMS.

Sneck, a town in the Netherlands, province Friesland, 13 miles SW. of Leeuwarden, with an active trade in agricultural produce, especially in butter and cheese. Pop. 13,000.

Sneeze-wood (*Ptaeroxylon utile*; family Sapindaceæ), one of the largest and most valuable trees in South Africa, sometimes yielding logs 80 feet long by 4 feet in diameter. The wood is of a yellowish colour, and has a handsome appearance somewhat resembling satinwood in the grain. It is difficult to work owing to its great hardness, but is believed to be very durable. It is employed for cabinet-making, for carpentry work, for fencing, and for engineering purposes. Neither the white ant nor the teredo, it is said, will penetrate it. Its native name is *Umtati*, and it derives its English name (a translation of the Dutch *Nes-hout*) from the irritating nature of the dust which results from sawing or otherwise working it.

Sneezing consists in a sudden violent expiration, preceded by one or more inspirations. During the expiration the fauces are generally closed so as to direct the current of air through the nose. Sneezing is most frequently produced by the presence of irritating substances in the nose, and indeed its purpose seems to be mainly to expel these from the nasal cavities. Irritants stimulate the terminal branches of the fifth nerve which are distributed over the nasal mucous membrane, and the stimulus conveyed to the 'respiratory centre' in the medulla leads to the respiratory efforts described. Sneezing is therefore a 'reflex act,' and as such is beyond the control of the will. It may, however, sometimes be prevented by the application of a strong stimulus to the nasal nerve, such as by compressing it at its exit from the nose, and it may also be prevented sometimes if a bet be made that it will take place. Sneezing may also be induced by irritation of other nerves than the nasal: thus, by gazing at a very bright light the strong stimulation of the optic nerves will sometimes bring on a sneeze. Sneezing not only rids the nasal cavity of foreign substances, but acts in a special way upon the general and especially the cerebral circulation. For the respiratory centre in the medulla is in close proximity to the vaso-motor centre, and the stimulus which leads to the sneeze produces at the same time increased activity of the vaso-motor centre, whereby the pulse is quickened, the blood-pressure rises, and the blood-vessels of the brain are dilated. Hence sneezing exerts a stimulant effect on the brain. Substances employed to induce sneezing are termed 'sternutatories' or 'errhines,' the principal ones being snuff, ipecacuanha, and euphorbium.

Paroxysmal sneezing is an expression of a special idiosyncrasy, and occurs most frequently, if not always, in persons of nervous habit. The attacks are often periodic, recurring like 'morning sneezing' with great regularity at certain times or under certain conditions. In others the attacks are provoked by the inhalation of dust or by particular odours. All these forms of morbid sneezing are due either to an increased irritability of the nerves in, or to chronic congestion of, the nasal mucous membrane, or to an increased excitability of the central nervous system, or to both, and they are largely maintained by habit. The disease is not

infrequent in persons of gouty or asthmatical tendencies. The treatment consists in the choice of a climate most suitable to the individual, but no rule can be laid down for any one case; in some cases change of air appears to exert little influence, in others a change even to the opposite side of a street will effect a cure. Diversion of the attention will often prevent the appearance of a paroxysm at its wonted time. The drugs employed most successfully in combating the affection are opium, morphia, the combined bromides or iodides of sodium, potassium, and ammonium, *Lobelia inflata*, and nerve tonics. Locally, sprays of adrenalin or ichthyol solution are useful. See HAY-FEVER. —The custom of formally invoking a divine blessing on one who has just sneezed is of venerable antiquity, and is very widely spread, but its real significance is by no means so easy to determine. Rabbinical legends connect it with Jacob, but it is not possible to give any fuller answer to Pliny's question, 'Cur sternutamentis salutamus?' than to say that it expresses respect to a divine intimation or to a natural sign of mortality. The most famous historical sneeze is that which was hailed as a good omen by Xenophon's ten thousand at a moment of despair.

Snehatten, a mountain of the Dovrefjeld (q.v.) in Norway, 7566 feet high.

Snell Exhibitions. See GLASGOW (UNIVERSITY).

Sniatyn, a town in the extreme south-east of Eastern Galicia, on the Pruth, 25 miles NW. of Czernowitz. Pop. 12,000.

Snider, JACOB, the inventor of a method for converting Enfield muzzle-loading rifles into breechloaders (see BREECH-LOADING, and RIFLES). Originally a Philadelphia wine-merchant, he busied himself in inventions connected with dyeing, brewing, coach-wheels, the sheathing of ships, &c., and crossed to England in 1859 to induce the British government to adopt his system of breech-loading or converting. In this he succeeded, but for one reason or another found himself unable to obtain the expected remuneration. He died 25th October 1866, worn out by delays, lawsuits, poverty, and debts.

Snipe, the name of a genus (*Gallinago*) and of a family (*Scelopacidae*) of birds, order Grallæ. The birds of this genus have a very long, straight, flexible bill, slightly elevated towards the tip of the upper half, which expands a little, is decurved at the point, and projects over the lower. The whole bill is smooth, soft, and extremely sensitive. The head is compressed; the eyes are large and are placed far back. The wings are moderate in size; the legs are rather long; the three toes in front are long, slender, and divided to the base; the hind-toe is slender. The Common Snipe (*G. gallinago*) is about 11 inches in entire length, the bill almost 3 inches. The sexes are alike in plumage, but the female is rather larger than the male. The general colour of the upper parts is blackish brown, finely mixed with pale brown and with a rich buff colour; three pale brown streaks along the head; the neck and breast pale rust colour mottled with black; the belly white. The tail consists of fourteen feathers. The snipe when flushed changes its course several times in a zigzag manner in the air, and then darts off very swiftly, so that young sportsmen find it a very difficult bird to shoot. The snipe makes a rough and ready nest of a little dry herbage in a depression of the ground, or sometimes in a tuft of grass or rushes. The eggs are four in number, large for the size of the bird, pale yellowish or greenish white, the larger end spotted with brown. This species of snipe is

plentiful in all the moory and marshy parts of Britain, and generally throughout Europe and as far as Iceland, also extensively in Asia, and it is found in the north of Africa, its representative in South Africa being a distinct species (*G. aquatorialis*). It breeds in Britain, even in the south of England, and migrates in autumn, to return in the following spring, while the winter birds are migrants from Scandinavia, arriving in the end of summer and departing in spring. The note of the

Common Snipe (*Hallinago gallinago*).

snipe is a *scape*, *scupe*; but especially at the breeding season the bird produces a peculiar drumming or bleating sound (hence the name 'heather-bleater' given to the snipe in Scotland) when executing its extraordinary aerial evolutions. The sound is due to the vibration of the two outer tail feathers as the bird shoots down through the air. Perhaps the stiff primaries of the wings help the sound, which is believed by some ornithologists to be produced by the female as well as by the male. The snipe is capable of being tamed, and becomes very familiar. A tame snipe has been known to eat nearly twice its own weight of worms in twelve hours. The snipe is in high esteem for the table, and is included amongst game in Britain. The habits of all the other species of snipe correspond very nearly with those of the common snipe. The Great Snipe, or Solitary Snipe (*G. media*), an annual visitor in small numbers to eastern and southern parts of England, very rare in Scotland and Ireland, but abounding in the extensive marshes of continental Europe, is found also in Asia and in many parts of Africa. Its entire length is about 12½ inches, the bill not quite so long in proportion as that of the common snipe. There are sixteen feathers in the tail. The Jack Snipe, or Judecock, usually referred to a separate genus, *Limnoryptes gallinula*, is the smallest of the group, and like the common snipe in plumage. It is common in Britain, but mostly as a winter visitant, and is found also during summer and winter in most parts of Europe and of the north of Asia and in North Africa. North America has a number of species. The Common American Snipe (*G. wilsoni*) is about equal in size to the common snipe of Europe, and much resembles it also in plumage, but has sixteen feathers in its tail. The name snipe is extended in popular usage to include the genus *Macrorhamphus*, in which the outer toes are connected at the base by a membrane. In other characters, as well as in plumage and habits, the similarity to the true snipes is very great. The Red-breasted Snipe, or Brown Snipe (*M. grisens*), of North America has been occasionally seen in Britain and in Picardy and Normandy. In size it is nearly equal to the common snipe.

Snipe-fish. See TRUMPET-FISH.

Snizort, LOCH, a large and picturesque inlet of the sea in the north-west of Skye, between Trotternish and Vaternish Points. It narrows from 9 to 3½ miles, and is 8½ miles long.

Snoring, an abnormal and noisy mode of respiration produced by deep inspirations and expirations through the nose and open mouth, the noise being caused by the vibrations of the soft palate and uvula. Sometimes the noise arises in the glottis, the vocal chords vibrating loosely. Keeping the mouth shut will usually make snoring impracticable.

Snorri Sturlason, an Icelandic historian and politician, was the son of a chief of the western fjords, and was born in 1179. The grandson of Sæmund Sigfusson, the compiler of the Elder or Poetic Edda, instructed him in the history, mythology, and poetry of the North, as well as in classical literature. By a wealthy marriage Snorri early sprang into a position of influence, and was elected (1215) supreme judge as well as president of the legislative assembly of the island. But his ambition, avarice, and love of intrigue led him to take part not only in private quarrels, but in the intestine troubles of Norway, and thus drew upon him the ill will of the Norwegian king, Hakon, who sent secret instructions to Iceland for his arrest, or, if need be, his assassination. The king's commands were carried out by one of Snorri's bitter enemies, who attacked him in his own house, and murdered him in the year 1241. Snorri was a poet of no mean order; and besides numerous laudatory poems on contemporary kings and jarls, he composed the Younger or Prose Edda (q.v.) and the *Heimskringla*; this last is a series of sagas or biographies of the Norwegian kings down to 1177, based on trustworthy sources and critically sifted evidence, and is written in a lively and interesting style. It has been translated by S. Laing (1844; new ed. by Rasmus B. Anderson in 4 vols. 1889).

Snow is the crystalline form into which the excess of vapour in the atmosphere is condensed when the temperature is below freezing. It is not, like hail or sleet, frozen rain, but is formed directly by the invisible aqueous vapour condensing in minute spicules of ice round the dust-particles that float in the air. More than 1000 different forms of crystals have been observed, and many of the chief or typical forms sketched or photographed by Scoresby, Glaisher, Bentley, and others; but in all of them the filaments of ice are arranged at angles of 60° or 120°, and they may be grouped into five classes. (1) Thin plates or stars of six rays (figs. 1 to 5), the forms getting more complex the lower the temperature. (2) A solid nucleus or a flat plate, with needle-like crystals projecting in all directions; fig. 7 is a section through one of these.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

(3) Fine hexagonal or three-sided prisms about ¼th of an inch long. (4) Prisms having thin plates perpendicular to their length: this form is rare (fig. 6). (5) Pyramids with six faces (fig. 8): this form also is rare, and is often associated with electrical disturbances. Each shower generally consists of flakes of one class only. Their form is best seen in calm weather; if there is much wind the crystals are broken and irregular, and during

gales tend to agglomerate in spherical masses. Perfect snow crystals are seen only when snow is formed at a temperature considerably below the freezing point of water. When the temperature is near the freezing-point, snow falls in agglomerations of snow crystals which are known as *snow-flakes*. Each flake consists of a matted network of snow-crystals, in which the form of crystallisation is usually obscured owing to partial thawing. The size of flakes varies from about an inch down to

Fig. 5.

$\frac{1}{16}$ th of an inch in diameter, the size being smaller the lower the temperature. The snow-fall of the British Isles is rarely so great as to cause serious inconvenience, except when accompanied by wind and consequent drifting: it then accumulates in railway cuttings and other sheltered places very rapidly, and to an extent limited only by the depth of the sheltered place. In the New England states the average annual fall ranges from 4 to 7 feet.

Fig. 6.

Fig. 7

Fig. 8.

In the Arctic regions and Siberia, though the fall is not greater than this, the snow lies unmelted much longer. To the south of lat. 40° snow is rare, except on hills; but it has been known to fall and lie for several days in Algeria and Morocco, and at Canton, within the torrid zone, it has fallen to a depth of 4 inches. Fresh-fallen snow is very light, owing to its looseness of structure—a foot of such snow gives only about an inch of water when melted; but it increases in density when lying, partly by compression due to its own weight, partly by the filling of the interstices with condensed and frozen moisture from the air, and greatly by partial thawing and refreezing. In this way the snow on mountains that rise to a height sufficient to have a temperature mostly below freezing gets hardened into *névé*, and ultimately into the ice of the glacier, by which it is transferred to lower regions; but if the depth on a steep slope gets too great before it has time to harden it is liable to sweep down suddenly as an avalanche of dry snow. On the other hand, the sudden melting of snow may cause dangerous floods, such as occur when the warm wind, called the Föhn, blows over the Alps; but the more gradual melting of the snow-mantle of hills feeds the deep-seated springs of

rivers. The snow of the Arctic regions, where solar radiation is weak, does not compact together, but remains dry and powdery; in eastern Siberia the prevalent wind is north-west, and all winter there is a continual drift of dry snow along the surface towards the south east. The white colour of snow is due to reflection of the light from the innumerable surfaces of the crystals, each of which is composed of clear ice, just as glass loses its transparency when pulverised. Snow is feebly phosphorescent, absorbing light during the day and giving it out at night. The loose texture of freshly fallen snow makes it an admirable non-conductor of heat, and in the temperate zone it often preserves the ground from the chilling action of short spells of intense cold. The latent heat set free when vapour condenses into snow also sometimes mitigates the severity of a frost.

In polar and alpine regions, where it lies unmelted from year to year, and the annual fall is small, snow is sometimes coloured red by the presence of innumerable small red plants. In its native state the plant consists of brilliant red globules seated on a gelatinous mass. It is an Alga, *Protococcus nivalis*; it is probably near akin to the not uncommon *Hamatococcus pluvialis*. Red snow seems to have been observed by the ancients, as a passage in Aristotle apparently refers to it; but it attracted no attention in modern times till 1760, when Saussure observed it in the Alps, and from chemical experiments concluded that the red colour was owing to the presence of some vegetable substance, which he supposed might be the pollen of a plant. The next observations on red snow were made in the Arctic expedition under Captain Ross, when it was found extending over a range of cliffs on the shore of Baffin Bay for 8 miles, the red colour penetrating the snow in some places to a depth of 12 feet. Less frequent is a green growth on snow. See also BACTERIA, BLIZZARD, ICE.

SNOW-LINE.—This is the usual term employed to signify the height below which all the snow that falls during the year is melted in the course of the summer, or, in other words, the limit above which snow perpetually lies. It is no hard and fast line, but varies greatly in different localities, and in most localities varies more or less from year to year. Hence it would be more appropriate to speak of a zone, having upper and lower limits, within which the snow-line moves up and down. The altitude at which this line (or zone) is found depends upon several conditions—the volume of snow precipitated during the winter, the amount of the rainfall and the position of the mountain-slope with reference to the principal rain-bringing winds, the latitude or distance from the equator, the degree of exposure to the sun's rays, the angle of the slope or the relative steepness of the mountain-side, and the general humidity or dryness of the atmosphere. Other things being equal, the following rules hold good: the snow-line is higher in north latitudes on the south than on the north side of mountains; higher on the east than on the west, owing to the greater prevalence of westerly winds in regions where snow accumulates; and higher in the interior of continents than near the sea, because in the former situations the precipitation is less and the heat of summer greater. In each separate locality the snow-line must be determined by a proper series of observations. To the general rules quoted above must be superadded those that depend upon the latitude: between 20° N. and 20° S. of the equator the altitude is pretty uniform; from 20° to 70° on both sides of the same central girdle it falls as the latitude increases in a pretty regular manner; but beyond 70° N. and S. and up to 78° in both directions it sinks very rapidly.

To these general rules there are of course in actual fact some important exceptions. In the Himalaya the snow-line runs 4000 feet higher on the north than it does on the south side; this is caused by the greater depth of snow that falls on the south side, by the greater dryness of the climate of Tibet, which increases the evaporation, and by the comparatively treeless rocks and barren soil on the northern side absorbing more heat than the well-wooded southern slopes. In the Andes the snow-line rises very rapidly between the equator and 18° S. lat., and more rapidly in proportion on the west than on the east side, owing to the comparatively small quantity of snow that falls on the Pacific side of the mountains. The subjoined table gives the snow-line on some of the most important mountain-ranges and peaks on the globe.

Snowball Tree. See GUELDER ROSE.

Snowberry (*Symphoricarpos racemosus*), a bushy shrub of the Caprifoliaceæ, a native of the northern parts of North America, and now very common in British shrubberies. It has simple leaves, small flowers, and white uneatable berries (pollinated by wasps), remaining on the bush after the leaves. The genus is North American, with one species in south-west China. The name Snowberry is also given to *Gaultheria serpyllifolia*, a native of North American bogs.

Snow-bird (*Fringilla hyemalis* or *hudsonia*), a North American bird of the Finch family (Fringillidæ), common from the Gulf of Mexico to the Arctic Circle, in all the eastern parts of North America. The wings are rather short, the tail slightly notched. The whole length is about six inches; the upper parts are lead-colour, the lower parts white, the two outer tail-feathers white, the next white margined with black. This bird migrates northwards early in spring, and southwards late in autumn. They are first found in small flocks; their favourite haunts are roadsides, but they always take to trees when disturbed. In cold weather they visit farmhouses and villages; and before a snowstorm they assemble in large flocks, visiting barn-yards, and hopping about with the domestic poultry and small birds. The song of the male in the breeding season consists of a few very low, sweet warbling notes. From its frequent familiar approach to human habitations, the snow-bird is regarded with favour throughout great part of North America, as the redbreast is in Britain. The name is also given to all the species of the fringilline genus Junco, including *J. hiemalis*, found both in the United States and in Canada.

Snow-bunting, or SNOWFLICK (*Plectrophenax nivalis*), a bird of the Finch family (Fringillidæ), Bunting sub-family (Emberizinae), abundant in summer in the Arctic regions generally, where it has been found nesting very far north indeed; in winter migrating southwards to Georgia in North America, to Japan, northern China, Turkestan,

southern Russia, the northern shores of the Mediterranean, and Morocco. In Iceland it abounds all the year round; in the Faeroes it is common in winter, and many remain to breed;

Snow-bunting (*Plectrophenax nivalis*).

in the British Isles it occurs in large flocks in winter, and it has also been found nesting on high mountains in Sutherland and in the Shetlands. It is a bird about 6½ inches long; plumage black and white; bill, legs, and feet black; but in autumn the feathers of the upper parts are broadly edged with dull chestnut, the bill is yellow with a black tip, and the bird is then known as the Tawny Bunting. In habits it differs in several respects from the true buntings: it runs rapidly on the ground, it also hops, and not infrequently perches on trees; and the song of the male while the female is on the nest is a low melodious warble. The food in summer consists of insects, in winter of seeds. The nest, made of dry grass and moss, and lined with hair and feathers, is in northern breeding haunts placed on the ground not far above sea-level; but in more southern latitudes it is generally built in rocks on the rugged sides of mountains. The flesh of the snow-bunting is palatable, usually fat; the Greenlanders kill large numbers, and dry them for winter use. See the article BUNTING.

Snowden, PHILIP, Labour statesman, was born in 1864 at Cowling, Keighley. He entered the civil service in 1886, but retired in 1893 crippled by a cycle accident, and became journalist, lecturer, and Socialist worker. After sitting for a time on Keighley town council and school-board, and making unsuccessful attempts to enter parliament for Blackburn (1900) and Wakefield (1902), he was chairman of the Independent Labour Party from 1903 to 1906, when he was elected for Blackburn. He was again chairman from 1917 to 1920. A leader of pacifist opinion, he lost his seat in the election of 1918, and only in 1922 re-entered parliament for Colne Valley. He was chancellor of the exchequer in Mr MacDonald's government (1924). He has written a number of books on socialism and labour. His wife, Ethel Annakin, is well known as a speaker and writer on similar subjects.

Snowdon, a mountain-range in Carnarvonshire, North Wales, stretches in a north-east-by-north direction from a point 5 miles N. of Criccieth, near the head of Caidigan Bay, to near Conway, but is broken up by valleys and river-courses into five distinct summits, the chief of which, Moel-y-Wyddfa ('conspicuous peak'), the highest mountain in south Britain, rises 3560 feet above sea-level. Seen from the top, Moel-y-Wyddfa, the 'King of Snowdonia,' appears to send out three ridges, which gradually divide and subdivide, giving birth to numerous valleys and corries. Its ascent is effected from Llanberis (on the north),

Beddgelert (on the south), Snowdon Ranger station (on the west), and Capel Curig (on the east). The first is short (5 miles) and the easiest—a railway was opened in 1896; the last the longest (9 miles) and most difficult, but far the grandest 'Snowdonia' was made a royal forest by Edward I. of England, and disafforested in 1649.—Snowdon was also an old name for Stirling.

Common Snowdrop
(*Galanthus nivalis*).

binge of spring flowers usually in Britain in February and March. Another species of snowdrop (*G. plicatus*), with much broader leaves, is found in the south of Russia and in Asiatic Turkey.

Snowdrop (*Galanthus*), a genus of Amaryllidaceae, of the same tribe with Amaryllis, Snowflake, Crinum, &c. The three outer segments of the perianth spread, so as to make a bell-shaped flower; the three inner are shorter, erect, and notched at the summit. The flowers arise from a spathe. The root is bulbous, and produces two leaves and one single-flowered leafless stem (*scape*). The Common Snowdrop (*G. nivalis*), a plant too well known to need description, is a native chiefly of the south of Europe, growing in woods and pastures. It is found apparently wild in some places both in England and Scotland, but is probably rather naturalised than native, having long been much cultivated in gardens. This welcome har-

Snow-shoes, a species of shoe whose broad

Snow-shoe.

surface prevents the foot from sinking in the snow. The Canadian snow-shoe (3 to 5 feet long and 1 to 2 feet wide) presents somewhat the shape of a tennis racquet with a short handle behind and long oval body contracted in front. It consists of a light frame of tough wood supporting a web of raw hide, to which, on the widest part, the foot is fastened by thongs, which leave the heel free. The Norwegian *ski* is simply a long, narrow wooden runner (5 to 10, but usually 8 feet long, by some 4 inches wide), about 1 inch thick at the middle, but thinner towards the ends, and turned up in a curve at the front (sometimes slightly at the back also).

Snuff. See TOBACCO.

Snyders, FRANCIS, a Flemish painter, born at Antwerp in 1579, studied under Van Breughel and Van Balen. Originally he confined himself to painting fruits, game, vegetables, and other typical models of still-life; but under the influence of Rubens, for whom, as well as for Jordaens, he frequently painted animals and still-life subjects to go in their larger pictures, he cultivated more especially the painting of animals. His bear,

wolf, and boar fights have hardly ever been surpassed. He painted a stag-hunt and similar hunting subjects for Philip III. of Spain. Snyders died at Antwerp in August 1657.

Soane, SIR JOHN, an English architect, born of humble parentage at Reading on 10th September 1753. He managed to get trained as an architect, and, having gained the travelling scholarship of the Royal Academy, spent three years (1777-80) in Italy. After his return home he secured several official appointments—e.g. architect to the Bank of England, St James's Palace, Office of Woods and Forests—and was elected professor of Architecture at the Royal Academy (1806). He designed numerous country-houses in the eastern counties and parts of public buildings (Bank of England) in London, showing in his plans considerable ingenuity, but an uncertain taste, and frequently a lack of harmony in his completed plans. At his death, in London on 20th January 1837, he bequeathed his own house in Lincoln's Inn Fields, and the valuable art and antiquarian museum it contained, including pictures by Hogarth, Reynolds, Turner, models by Flaxman, the MS. of Tasso's *Gerusalemme Liberata*, &c., to the nation. He published amongst other books a set of folio plates of *Public and Private Buildings* (1828), and a *Description* (1832) of his own house and museum.

See the Memoir by J. Britton (1834), and the *Art Journal* (1882).

Soap is the term applied to that class of compounds formed when alkalis act on fats or fatty acids. Chemically it includes also the insoluble compounds formed from metallic oxides, as lime, litharge, &c.; but industrially it is mainly confined to the compounds of soda and potash. Soap is first mentioned by Pliny, who states that it was prepared from goat's tallow and beech-tree ashes, and was employed for giving brilliance to the hair. The excavations at Pompeii brought to light a complete soap-making establishment, containing some well-preserved soap. The industry, however, advanced very slowly, and it is only within comparatively recent years that it has really flourished. The most important discoveries which assisted its development and led to its present enormous proportions were Chevreul's researches on the constitution of fats and Leblanc's process for the manufacture of soda on a large scale. It has also been stimulated in Britain by the repeal in 1853 of the duty (amounting to from 1d. to 3d. per lb.), first imposed in 1711. Chevreul showed that the neutral fats are mixtures of 'glycerides,' consisting of glycerine combined with the elements of certain fatty acids. In the process of saponification the fat is decomposed, the fatty acids combining with the alkali to form soap, while the glycerine is set free.

Soaps are distinguished as 'hard' (soda-soaps) and 'soft' (potash-soaps). They have a characteristic taste, and are soluble in hot water and in alcohol. When agitated with water a 'lather' is produced, and when their hot concentrated solutions are allowed to cool, jellies are formed. Salt precipitates them from their solutions, but in the case of a potash-soap double decomposition takes place, with the result that a large proportion of soda-soap and potassium chloride is formed. Many theories have been advanced to explain the cleansing power of soap; it was formerly suggested that this was mainly due to the action of a small proportion of free alkali and acid soap which is formed when soap is dissolved in a large volume of water. This is now believed to be quite secondary, as the cleansing effect mainly depends on the penetrating and emulsifying property of the soap in solution.

The principal fats and oils employed in the

manufacture of soap are refined tallow, palm oil, palm kernel oil, coconut oil, cotton-seed oil, soya-bean oil, ground-nut oil, and fatty acids obtained either by distillation from residues or from the oils and fats by being subjected to a preliminary splitting process, whereby the glycerine is separated from the fatty acids. The efficiency of a soap depends in a great measure on the proper blending of these oils and fats; for hard soaps a large proportion of tallow and nut oils is used, while for soft soaps the liquid oils such as cotton, soya-bean, and linseed oil are the chief constituents. Rosin enters largely into the composition of the lowest grade soaps, both hard and soft; and while a small proportion of this ingredient is generally accepted to be advantageous, an excessive proportion is detrimental, and is to be deprecated.

The following processes, arranged in order of simplicity, are those used in the manufacture.

(1) The direct union of free fatty or resin acids and alkalis.—This process is being more generally used, on account of its simplicity, by small manufacturers, as fatty acids combine at once with caustic lye, and there is no glycerine to recover. The process is much the same as that detailed below, except that the alkaline lyes are run into the pan first, and then neutralised with the exact proportion of fatty acids. When all the free fatty acids are neutralised a slight excess of caustic lye is added, and the mass boiled to complete the saponification of any neutral fat or oil. The process may then be continued as described for any of the processes below.

(2) Treatment of fats with definite quantities of alkali, the glycerine remaining with the soap; known as the 'cold process.'—Given weights of fat are melted at a suitable temperature, and mechanically mixed in a pan with a definite quantity of caustic lye of known strength, just sufficient to effect complete saponification. After standing from one to four days, according to the quantity, saponification is complete and the soap is hard enough for use. This process possesses the advantages of economy of labour, fuel, and plant, but the resulting soap contains all the glycerine of the oils and fats used, and is liable to contain free caustic alkali; so the process is only used by small manufacturers, or for special soaps, when the retention of the glycerine is advantageous.

(3) Treatment of fats by boiling with alkaline lyes.—This process is the most important of the three, and will now be described as it is carried out for hard soaps.

Hard soaps constitute the great bulk of the soaps used, and may be divided into three varieties—curd, mottled, and yellow. The general method is the same for the three. The vessel used (called the 'pan') is made of wrought-iron plates riveted together, and is fitted with coils for supplying open and close steam. Pans are now generally of square form, and capable of turning out from 20 to 30 tons of soap at one operation, although some of them are much larger. In the first stage (called 'killing') a quantity of the fat is melted in the pan, weak caustic lye added, and the steam turned on. The mass becomes pasty after some time, and the boiling is continued, and the fat and lye added, until a sample appears somewhat firm, and has very little or no caustic taste. In the second stage ('graining the soap' or 'salting') the water is separated from the soap (the boiling being continued) by the cautious addition of common salt, or strong brine, until clear liquor runs from a small sample taken out. After standing for a few hours the 'spent lye' (containing the bulk of the glycerine of the fat, common salt, and the impurities of the caustic soda) is removed. In the third operation ('clear

boiling') the granulated soap is boiled for two or three hours with fresh lye, in order to cause more complete saponification, and to remove the brine retained by the soap. After settling the lye is removed, and may be used for the treatment of more fresh fat. The contents of the pan are again boiled with open steam and lye for several hours, to complete the saponification of the last traces of fat, and 'make' the soap.

The method of finishing the soap varies with the kind of soap required, and will now be explained under the names of the different varieties.

Of *curd soaps* the finest quality is made from tallow, but other fats may be used. When the soap has been 'made,' as just explained, it is concentrated by means of close steam, until a sample appears hard. The boiling is then stopped, and the soap allowed to settle, then removed.

Mottled soaps, as far as composition is concerned, are practically curd soaps; darker fats, however, are used in their manufacture, and after the soaps have been 'made,' the lye is not concentrated so far as with curd soaps. Many precautions require to be observed in order to obtain the natural 'mottling' which characterises them. It is due to the presence of small quantities of lime, magnesia, &c., from the materials used, and to oxide of iron from the pan. These oxides form insoluble soaps, and when the soap, retaining a little lye, is transferred to the cooling-frames, they collect together, producing the well-known appearance. Natural mottling is assumed to be a guarantee of the absence of an undue amount of water in a soap. Artificial mottling of inferior qualities of soap with ultramarine, oxide of iron, &c., has been largely practised. Mottled soaps are used for laundry work and similar purposes.

Yellow soaps contain rosin as an essential constituent. The finest qualities are made from the best tallow and light-coloured rosin; inferior qualities from darker tallow, bleached palm oil, &c., and darker rosin. The rosin is usually introduced after the second stage of the general process. The finishing operation, or 'fitting' of yellow soaps, requires much experience. After the soap has been 'made,' the pan is allowed to stand for about twelve hours, the lye removed, and the soap well boiled until homogeneous, with some fresh lye if necessary. When a sample has been found to be in the proper state, the pan is covered up, and allowed to stand for some days, when a separation into three layers takes place—the scum or 'fob' on the top, the 'nigre' (or dark alkaline soap-lye) underneath, and the finished soap in the centre, which is then removed to frames. The nigres are utilised in the making of darker soaps. The principal soap-manufacturers now recover the glycerine from their spent lyes.

For *marine soap* coconut oil is mixed with strong caustic lyes at 30° to 35° C., and after standing some time, sufficient heat is liberated to effect almost complete saponification. The soap is not salted out, but the 'fillings,' if required, are added direct, when the soap is transferred to frames, where it is allowed to cool. The sides of the frames are then removed, and the solid block of soap is cut into slabs, bars, or tablets as required. The 'fillings' are certain substances, added either with the view of increasing the detergent power of the soap, or simply to lessen the cost. Silicate of soda belongs to the first class, and is used with advantage in certain soaps. Such substances, however, as water, talc, clay, chalk, barium sulphate, &c., must be looked upon merely as adulterants.

Soft soaps are made by saponifying liquid oils, as stated above, with caustic potash, the glycerine usually, though not necessarily, being left in the

soap, which often contains a little free alkali as well. They form transparent jellies, and often exhibit, in cold weather, a white graining, or 'figging,' due to alkaline stearates. The oil is run into the pan, potash lye added, and the steam turned on. The boiling is continued, latterly by close steam or fire heat, and lye added, until a small sample appears clear on cooling, and no liquid separates from it. When finished the soap is run into barrels or tins.

For *toilet soaps* the base or 'stock' of the better qualities is generally curd soap, special precautions being taken to ensure absence of free alkali. The finest toilet soaps are now 'milled.' For this purpose the soap is cut into shavings, dried partially, the colouring material and perfumes added, and passed several times between granite rollers to make it perfectly homogeneous. It is then subjected to great pressure, or 'plodded' to form it into bars, which are afterwards cut and stamped into tablets. The lower qualities of toilet soaps are frequently made by the cold process.

'Transparent' soaps are prepared by dissolving good dry soap in alcohol, pouring off the clear solution, and removing the bulk of the spirit by distillation. The remaining soap is transferred to moulds, allowed to cool, and preserved in warm chambers for several months, until it becomes quite transparent. Many transparent soaps, however, are made by the cold process, their transparency being obtained by the addition of sugar. Glycerine is often added to both opaque and transparent soaps, imparting to them its characteristic emollient properties, while such substances as carbolic acid, coal-tar, eucalyptus oil, &c., are added to soaps intended for disinfecting purposes.

The following table gives the average composition of some genuine soaps of English make :

	Fatty Anhydride.	Alkali (Na ₂ O)	Water.	Salts	Glycerine and Salts
Curd	63.21	8.44	26.76	1.59	..
Mottled..	64.17	7.80	25.66	2.37	..
Yellow (best)	61.95	7.07	30.45	0.53	..
Marine	52.65	8.55	30.03	.	8.77
Toilet ('milled')	80.06	9.56	9.11	1.27	..
		(K ₂ O)			
Soft..	40.36	9.18	44.78	..	5.68

The commercial value of soap depends upon its percentage of fatty anhydride. Soap is used otherwise than as a detergent—as a base in making pills and plasters, in liniments, and as a test for the hardness of Water (q.v.).

See G. Martin, *Soap and Detergent Industry* (vol. i., 'Theory and Practice of Soapmaking,' 1923); E. G. Thonssen, *Soapmaking Manual* (1922); C. Deite, *Manual of Soapmaking* (1920); J. Lewkowitsch, *Chemical Technology of Oils, Fats, and Waxes* (6th ed. 1922); Hurst and Simmons, *Textile Soaps and Oils* (1914); L. Ubbelohde, *Chemie der Oele, Fette und Wachse* (1908).

Soapberry. The fruits of several species of trees belonging to the genus *Sapindus* (family Sapindaceæ) contain a pulp which is useful as a substitute for soap in cleaning linen and other textile fabrics. In the West Indies the fruit of *Sapindus Saponaria*, and in the East Indies those of *S. trifoliatum*, and *S. attenuatus* are much used for this purpose. The frothy mixture which these fruits make with hot water is said to be very serviceable for cleaning dyed fabrics which soap would injure. In France silk stuffs are cleaned with the seed vessels of *S. emarginatus*. The seeds of *S. Saponaria* are made up into rosaries, and were formerly worn in England tipped with gold, silver, &c., as buttons.

Soap-bubbles. As a form of amusement for children the blowing of soap-bubbles is of great antiquity, and is to be seen depicted on an Etruscan vase in the Louvre. In their scientific aspect soap-bubbles and soap-films have been studied specially by Plateau, who, by adding glycerine in a certain proportion to the soap solution, obtained remarkably durable films and bubbles. The beautiful play of colours familiar to all is due to the excessive but variable thinness of the soap-film. It is in fact an illustration of the interference phenomenon known as Newton's Rings (see INTERFERENCE, NEWTON). If at any part the film becomes thin enough the black spot appears. If this black portion is touched the film is shattered at once, although it may in its thicker portions be pierced by a needle without losing continuity. The spherical form of the ordinary soap-bubble is a direct result of the action of Surface-tension (q.v.), the geometrical condition being that with given volume the surface must have minimum area. With soap-films formed on frames of wire the same principle holds—for given boundary and given internal volume the area must be a minimum. Thus, by a skilful arrangement of soap-films, we may make visible many highly interesting problems in pure mathematics. See *Soap-bubbles*, by Professor Boys (S.P.C.K., 1890).

Soap-root. See SOAPWORT.

Soap-stone. See STEATITE.

Soap-tree. See SOAPBERRY.

Soapwort (*Saponaria*), a genus of plants of the family Caryophyllaceæ, having a cylindrical or ventricose five-toothed calyx, without any outer calyx or attendant bractes, five undivided petals with long claws, ten stamens, two stigmas, and a capsule opening at the top by four valves. Some of the species have very beautiful flowers. *S. calabrica* is one of the most favourite annuals of British flower-gardens. Common Soapwort (*S. officinalis*) is found on waysides, in thickets, and on the banks of streams in most parts of Europe, although it is a somewhat doubtful native of Britain. Both the root and the leaves contain Saponin (q.v.), in consequence of which they are sometimes employed for washing. The brownish-red colour of the bark of the root, however, is apt to tinge white articles. The root of this plant has also medicinal properties, being aperient, resolvent, and alterative. It is sometimes sold as Red Soap-root.

Soapwort (*Saponaria officinalis*).

Nearly allied to the genus *Saponaria* is the genus *Gypsophila*, some species of which are called Soap-root, and contain much saponin. Thus, the Egyptian Soap-root (*G. Struthium*), and the Spanish Soap-root (*G. hispanica*), called *Jabonera* in Spain, have been employed for washing from time immemorial, and the roots, not having a dark rind, can be used for washing white articles, and are to some extent an article of commerce, being used for silken and other stuffs, the colours of which will

not bear the application of soap. The roots of *Lychnis divica*, one of the most common British plants, possess the same properties in an inferior degree. The bark of the Chilean Soap-tree (*Quilaja Saponaria*), of the family Rosaceæ, contains much saponin, is generally used for washing in Chile and Peru, and there forms a considerable article of commerce. It is said to give a remarkable lustre to wool, and to be an invigorating wash for the hair. Some of the tropical South Sea Islands produce a species of vine (*Vitis Saponaria*), the stem of which, especially the thicker part, cut into pieces, and softened by cooking on hot stones, produces in water a rich lather almost equal to that of soap. See also SOLANUM.

Sobat, a tributary of the Nile (q.v.).

Sobbing is merely a modification of the ordinary movements of respiration excited by mental emotions. It is the consequence of a series of short convulsive contractions of the diaphragm, and is usually accompanied by a closure of the glottis, preventing the entrance of air into the lungs.

Sobieski, the surname of JOHN III., king of Poland, one of the greatest soldiers of the 17th century, who was born at Olesko in Galicia on 2d June 1624, his father being castellan of Cracow. He early distinguished himself in the wars in which Poland was at that period almost constantly engaged, against the Russians, the Tatars, and the Turks. Upon the last he inflicted crushing defeats at Buczacz (in Galicia) in 1669, and at Choczim (Khotin) on 11th November 1673, capturing the green standard of Hussein Pasha, commander of the Turks, and slaying more than 20,000 of his soldiers. In the next year he was chosen king of Poland. A high-minded, brave, and disinterested man, and a shrewd statesman, he conceived it to be his special mission to contend with all his energy and power against the enemy of Christendom that threatened from the shores of the Bosphorus. He again routed the Turks at Lemberg in August 1675, and in 1676 successfully defied their utmost efforts to storm his entrenched camp near the Dniester. After a truce of five years—a breathing-time employed by the sultan to gather fresh armies and war material—the Turks once more overran Hungary, and even laid siege to Vienna. Sobieski, always swift in his marches, and vigorous and determined in his attacks, hastened to its relief at the head of 18,000 Poles. With these, and 50,000 German troops, who joined him on the way, he smote the great Turkish army so terribly, on 12th September 1683, that the siege was at once raised and the Turks hastened to retire. Sobieski died at his castle of Willamow on 17th June 1696. This prince was a lover of books and of knowledge, and himself a clever linguist.

See books by Salvandy (1876), Dupont (1885), and Tatham (1881); and Waliszewski's *Marysienska* (trans. 1899).

Sobral, a town of Brazil, in the province of Ceara, on the Aracaty, 78 miles by rail SSE. of the seaport Camocim; pop. 35,000.

Sobraon, a village of the Punjab, on the west bank of the Sutlej, opposite which, on the east bank, was fought on 10th February 1846 a most obstinate battle between the British under Sir Hugh Gough and the Sikhs (q.v.), which put an end to the first Sikh war.

Socialism. Socialism is defined in the *New English Dictionary* (1919) as 'a theory or policy of social organisation which aims at or advocates

the ownership and control of the means of production, capital, land, property, &c., by the community as a whole, and their administration or distribution in the interests of all.' This definition, though somewhat diffuse, would be accepted by most socialists.

Robert Owen.—The word appears to have been first used in English in *The Poor Man's Guardian* in 1833, and it became familiar in 1835 in connection with Robert Owen's *Association of all Classes of all Nations*. Owen (1771–1858), who may be called the founder of the socialist movement, chose this name for his ideas in order to distinguish his policy of social reconstruction from the political reforms advocated by others. His schemes were devised for the purpose of introducing socialism by private enterprise. He supposed that it was possible for a few people voluntarily to carry out his principles, and to live in accordance with his ideas in the midst of a capitalist society. Experience has shown that such projects always fail, and Owen's attempts broke up before they were well started. But it must be remembered that the great co-operative movement, begun as the result of his teaching by the Rochdale pioneers in 1844, is, in fact, socialism for a limited range of purposes, and has succeeded within these limits in the midst of capitalism. It is now believed by many that the co-operative movement will find a place without material change, in any socialist state which may be established. Owen attempted to found communities, associations of a few hundreds or thousands of people living together in a central building or village, cultivating 1000 or 1500 acres of land, producing for themselves food, clothes, and other necessities, and jointly owning the land and capital employed. Of course the communists promptly quarrelled, and, for ordinary people, any such project was economically unsound in Owen's day, and is obviously absurd now. The communities which have here and there succeeded in America sometimes even for a generation, have been cemented by special religious beliefs, as those of the Shakers.

The Christian Socialists and J. S. Mill.—The social unrest created by the industrial revolution, that is, the introduction of machine industry and of capitalist production, was too deep-seated to be dispelled by the failure of Owen's schemes. The Chartist movement (1838–1850) was socialist on its critical side, that is, in so far as the speeches and writings of the Chartists were coloured with passionate protests against the evils of capitalism, and to some extent also in the esoteric projects of its leading thinkers. Chartism too failed, and was succeeded by the Christian Socialist movement of 1848–1852. This was led by F. D. Maurice and Charles Kingsley, and was definitely socialist on its critical side only. The remedy advocated was the formation of co-operative societies of producers, groups of workmen owning the capital with which they worked, and selling their products for profit. This form of co-operation is not in harmony with socialism, and only under exceptional circumstances does it seem able to compete with capitalist production; so failure again followed. Meanwhile the grosser evils introduced by the industrial revolution were gradually mitigated by Factory Acts, Truck Acts, Public Health Acts, Education Acts, Housing Acts, and the growing strength of Trade Unionism. Labour unrest diminished, and the demand for drastic social change died away. Nothing more was heard of popular socialism in England between 1860 and 1880.

But there was one clear thinker who saw farther ahead than his contemporaries. John Stuart Mill (1806–1873), the most influential of English political writers during the 19th century, was for many

years regarded almost as a pope in the realm of economics, and it is therefore strange that his extremely sympathetic description of the very impracticable forms of socialism known to him attracted so little attention. In his *Principles of Political Economy*, which went into six editions between 1848 and 1863, he sums up his discussion of communism with the pregnant words, 'It is for experience to determine how far or how soon any one or more of the possible systems of community of property will be fitted to substitute itself for the "organisation of industry," based on private ownership of land and capital.'

Early French Socialists.—Mill had chiefly in mind the writings of two Frenchmen. One of these was Comte Henri de Saint-Simon (1760-1825), who in the last decade of his life published works advocating the reconstruction of society on communist lines. A community was founded by his followers in 1831, and lasted about a year. The other, François M. C. Fourier (1772-1837), drew up plans for a '*phalanx*' of 400 families living on a square league of land, in a '*phalanstère*', that is, a central building adapted for communal life. Both these thinkers, though their ideas are now entirely superseded, had considerable influence amongst political idealists in the middle of the 19th century.

Louis Blanc (1811-1882) was the next prominent socialist. His *L'Organisation du Travail* attributed the evils of society to competition, and demanded the establishment of 'social workshops,' self-governing and self-supporting, but promoted and financed by the state. It was from him that the Christian Socialists in England derived their projects of similar workshops without state aid. In the revolution of 1848 Blanc became a member of the provisional government, and busied himself with the formation of his social workshops, which were not altogether without success. Meanwhile, however, other ministries set going on a great scale in Paris what were termed 'national workshops,' but what were, in fact, mere relief works for the temporary maintenance of the unemployed, entirely without reference to the reconstruction of industry. These relief works were, for reasons that have since been well understood, a calamitous failure, and at once Blanc disclaimed all responsibility for them. They are almost invariably confused with his entirely different experiment. He lived in England in exile until 1870, when he returned to France, took no part in the Commune, was elected to the National Assembly, and after his death had a state funeral.

German Socialists.—The leadership in socialist thought now passed to Germany, where, in the opinion of most foreign socialists it remained until the Great War. Karl Johann Rodbertus (1805-1875) may be mentioned as one of the forerunners. He was the son of a professor, was a Prussian landowner, and took only a brief part in politics during the revolution of 1848. His economic writings had great influence on Lassalle and Marx, and he has a disputed claim to be the originator of what is called 'scientific socialism.'

Ferdinand Lassalle (1825-1864) was a more important personage, whose meteoric career was cut short by a tragedy which forms the theme of George Meredith's *Tragic Comedians*. He was a Jew by birth, and after a university education, became well known in Berlin as a man of extraordinary abilities. A law-suit on behalf of the Countess Hatzfeldt occupied some eight years, during which, in 1848, he joined the group of Marx, Engels, and others. In 1862 he began socialist agitation with lectures, addresses, and publications, including a Working Men's Programme. A triumphal progress through the

country followed, and in 1863 the Universal German Working-men's Association was founded with Lassalle as president. In August 1864 he was killed in a duel on behalf of the lady he was engaged to marry. He followed Louis Blanc in advocating workmen's productive associations provided with state capital, but in other respects his general ideas were similar to those of Marx, and it is not necessary here to discuss their points of difference.

Karl Marx.—We now come to the greatest figure in the history of socialism, Karl Marx. Future historians will dwell on the strange contrast between the obscure life and posthumous fame of this Jew. Born at Treves in 1818, expelled from Germany at the age of twenty-seven, he spent the rest of his life as an exile in London, reading at the British Museum, writing for American newspapers, corresponding with groups of revolutionists and agitators in Germany and elsewhere, but so little known to the English public that on his death on the 14th March 1883 the brief obituary paragraph in the *Times* begins with the words, 'Our Paris correspondent informs us of the death of Dr Karl Marx in London.' Yet this obscure student, through his ideas mainly embodied in *Das Kapital*, in less than forty years proved to be a force that had determined the destinies of two great empires, and seems certain to play a part in the history of every civilised country of the world. Of his life little need be said. He was the son of a lawyer; was educated at the universities of Berlin and Bonn; edited a newspaper in 1842; married a lady belonging to the official class, who was a descendant of the Earl of Argyll beheaded by James II.; met his life-long friend and collaborator, Friedrich Engels (1820-95), at Paris in 1844; was expelled from Paris and settled in Brussels; returned to Germany in the year of revolutions, 1848, and finally settled in London in 1849. His wife died in 1881, leaving three daughters. One of these, Eleanor, was well known in the early socialist movement in London; the other two married in Paris; and his grandson, M. Jean Longuet, is a well-known leader of the French socialists.

Marx's Scientific Socialism.—We now turn to Marx's writings. In 1847 he and Engels published the *Manifesto of the Communist Party*, which advocated the socialism of a proletarian state, and is generally regarded as the first exposition of modern socialism. It may be useful here to point out the four stages in the use of the words Communist and Communism, which must be carefully distinguished. (1) In the first half of the 19th century Mill and Marx used the word as a synonym for socialism. (2) After the insurrection of the Paris Commune in 1871 its adherents were called communists because they advocated the autonomy of the commune or town council of Paris. (3) Subsequently down to 1916 communism meant the principle of common ownership without restriction, as in the communities of Robert Owen and others, in the name 'communist anarchists,' adopted by the adherents of that creed, and, as applied to politics, in the parks, roads, public libraries, &c., provided for the public free of charge; and communism, 'each according to his needs,' was regarded as an alternative to socialism, 'each according to his deeds.' This usage is probably confined to the English language. (4) In 1917 Lenin adopted the name communism for his policy in order to distinguish it from that of the majority of the German socialists who had supported their government during the war; and since that date the name communist has come to be applied exclusively to the adherents, inside and outside Russia, of the Russian school of socialism,

which is rigidly Marxian with special stress on certain doctrine of policy.

The 'party' mentioned in the title of the *Manifesto* was some temporary organisation in London of no other consequence. The *Manifesto* has been translated into innumerable languages, and reprinted countless times. In 1867 Marx published the first volume of *Das Kapital*, the book on which his reputation rests. Two subsequent volumes were prepared after his death from MS. drafts and notes arranged and edited by Engels, and a fourth has been issued. His other works, mostly concerned with contemporary controversies, are of minor importance. It is difficult to understand how it has happened that Marx, an obscure exile throughout his life, has since his death become a prophet almost as influential amongst large sections of people as Mahomet, or Buddha, worshipped by thousands in fact, though not in form, as if he were a god. England and the British dominions have been free from this strange superstition; but in the United States, throughout Europe, and, above all, in Russia, it is, or has been, a vital force. It began indeed in Marx's life-time, and we are justified in calling it a superstition, because Marx himself once said to his son-in-law, Paul Lafargue, 'one thing is certain, and that is that I am not a Marxist.' The socialists who preceded Marx endeavoured to build up socialism within the community, just as religious sects or co-operative societies have been built up. Marx proposed that the community as a whole should become a socialist state, and this new and correct view of the significance of socialism is the justification for the outstanding position which he holds amongst the founders of the movement. He based his theory partly on history and partly on economics. His 'economic interpretation of history' is the thesis that economic conditions are the determining factors of history, as, for example, that the old Roman Empire was destroyed by slave labour on *latifundia* dispossessing the Roman peasantry. As capitalism had replaced peasant and handicraft industries in England and Germany, and was in process of replacing them everywhere, so the next step would be the change from capitalism to socialism. Everywhere big capital was ousting small because of its inherent strength. Marx anticipated that capital would steadily and inevitably pass into fewer and fewer hands; the people would become in ever increasing proportions, 'proletarians,' that is, workmen solely dependent on wages, 'with nothing to lose but their chains,' and at last, when a little group of wealthy possessors was confronted by a nation of proletarians, the revolution would break out and socialism would be established. It must be remembered that Marx lived in the era of revolutions, 1830, 1848, 1871, when Garibaldi, Kossuth, Mazzini, and many others were popular heroes.

The 'Marxian law of value' was the second principle on which he based socialism. Labour, he said, following Ricardo, or rather Thomas Hodgskin and William Thompson, whose scarcely-noticed works he read at the British Museum, is the sole source of wealth. The capitalist, possessing machinery and raw materials, hires labour which creates value in the product. Part of this value goes to pay wages and incidental expenses. The remainder is 'surplus value,' the employer's profit which his economic power enables him to take from the workmen who were its creators. The workman works so many hours in each day to produce his wages for himself, and the latter hours of each day's work are for the profit of the employer. The capitalist ever eager for more surplus value, introduces more machinery and

so displaces labour. More goods are produced than consumers can take. Then follow gluts, and commercial crises. These grow constantly more severe; the *bourgeoisie* proves incapable of controlling the monster which it has created. The commercial system breaks down, and the revolution supervenes. After the revolution the private ownership of land and capital would cease; both would be owned and controlled by the state, for the benefit of the community as a whole. 'Exploitation' of labour by capitalists would come to an end, and the 'wage system' would perish with it.

The First International and Anarchism.—Marxian socialism first came into notice through the First International, which was started in London in 1864 as a result of the visit of French workmen to the Exhibition of 1862. Mazzini proposed a constitution, which was rejected in favour of a draft by Marx, who thenceforth became its virtual chief. Conferences were held at Geneva in 1866, at Lausanne in 1867, at Brussels in 1868, at Basel in 1869, and at the Hague in 1872. The last was famous for the culmination of the controversy with Bakunin and the anarchists, who were defeated by Marx and expelled. We must now turn aside to describe in a few words this form of socialism, as it may be called from one point of view, though from another it is the antithesis of socialism. Modern socialism following Marx regards the community as a whole, that is in effect, the government, as the proper possessor of land and capital, and the rightful administrator of industry. But in Russia the government, up to the fall of tsarism (and some would say after it), was generally regarded as a malign force. The Russian village was a self-supporting community and the government only touched it to collect taxes, to take away men for the army, and occasionally to repress free political thought. Russians, thinking in terms of their villages, imagined that the ideal life was for each to possess the land and instruments of production which he used, so long as he used them. Government with its taxes, and its army and its police, might be abolished, and all would be better off without it. There would be no rich and no poor, and hardly any crime, since most crime is against property. The village commune, the mir, which controlled the distribution of the land, would be all the government needed. It is true that the first anarchist writer, P. J. Proudhon (1809-65), was a Frenchman, who is best remembered by his saying 'property is robbery.' Michael Bakunin (1814-76), Prince Peter Kropotkin (1842-1921), and Count Leo Tolstoy (1828-1910), were all Russians; the last-named, though anarchist in his teachings, took no part in the organisation of the anarchist party. Anarchist-communists opposed all government, and worked for an ideal form of society in which property would be held in common, as in a family, each appropriating land and tools only as long as he used them. Such an ideal is hardly compatible with machine industry, even in words; a railway under anarchism can hardly be described. But the ideal is attractive to artists and poets, and William Morris, as indicated in his romance *News from Nowhere*, had more real sympathy with anarchism than with the Marxist collectivism to which he nominally adhered. Holding the belief that 'government of man by man is oppression,' anarchists were always disposed to rebel against the oppressor. Ill-balanced persons and criminals often joined their ranks, and assassination of princes and governors by dynamite or other means was frequently resorted to. Anarchism was a factor in the socialist movement until after the end of the 19th century. It prevailed chiefly in the Latin countries, especially in Spain.

In Germany and in England it was at no time of great importance, and in this country it has been little heard of in the present century. Its later developments will be dealt with further on.

The Progress of Socialism in Germany.—The battle-royal between Marx and Bakunin broke up the First International, which finally petered out in 1873. Meanwhile a socialist movement had been growing up in Germany. Lassalle's vivid personality and whirl-wind agitation of 1863-64 had borne fruit of two kinds. His Universal Working Men's Association made progress in north Germany; in the south and in Saxony a rival network of workmen's educative associations was formed, which soon tended to move in the same direction. At the congress of these associations at Nurnberg in 1868 the principles of the International were accepted, and at Eisenach in 1869 the Social Democratic Working-men's Party was founded. The two parties, both represented in the Reichstag, kept separate until 1875 when they were amalgamated, and in 1877 they polled nearly half a million votes. By this time their two great leaders had emerged, Wilhelm Liebknecht (1826-1900) and August Bebel (1840-1913), who held undisputed control of the party from its formation to the end of their lives. Liebknecht, after a university education, had a remarkably adventurous career, until about 1849 when he came to London and lived for thirteen years in close association with Marx. In 1862 the amnesty enabled him to return to Germany; in 1867 he was elected to the Reichstag, and in 1872 he was condemned to two years' imprisonment for treasonable intentions. From 1874 till his death he was continuously a member of the Reichstag and leader of the Social Democratic party. Bebel was a wood-worker by trade, and became a follower of Liebknecht. He too was elected to the Reichstag in 1867, and these two were the only members who opposed the Franco-German war. He also was condemned to two years' imprisonment in 1872. After this period his eloquence and energy gave him a commanding position in the party which he retained until his death.

Under the leadership of these two men the German Social Democratic party made steady and remarkable progress up to the outbreak of the Great War. Bismarck's anti-socialistic laws of 1878 were but a temporary set-back, and by 1912 the party cast 4,250,329 votes, and elected 110 members to the Reichstag. In fact they were entitled to many more, as they controlled all the big towns, including Berlin, and the other industrial centres, all of which in the absence of redistribution since 1871 were grossly under-represented. The party was thoroughly organised, and had in 1914 1,085,905 paying members, 91 newspapers and journals, and a head-office income of £100,000. German socialism was strictly Marxist, and this meant a policy of antagonism and isolation. The Marxists have always regarded socialism as a plan rather than a principle, and have themselves usually acted on the maxim, 'He that is not with us is against us.' In theory, though not altogether in practice, they opposed all measures of the government, made no alliances with other parties, and saw no good in any other movement. The two great leaders were the pillars of Marxian orthodoxy, but after 1901 when Eduard Bernstein, a social democratic leader who had lived as an exile in London since 1888, returned to Germany a 'revisionist' movement was started. Bernstein had learnt in England that Marx had not written down everything there was to be said about socialism, and largely through his efforts a more liberal spirit was making progress amongst the

German socialists when the war opened a new chapter.

Socialism in France and elsewhere.—The German Social Democratic party was remarkable for its solidarity. Such disputes as arose were settled within the party. Secessions were rare and negligible. Far otherwise was the case in France. Here the important socialist movement has a history of faction fights, quarrels, and reconciliations. Prominent leaders have been expelled or have deserted, and, such as Millerand and Briand, have subsequently become ministers in Republican governments. The party achieved great electoral successes, although it never had an efficient organisation like that in Germany, or like the Labour party in England, and its central income was stated to be in 1913 no more than £6380, largely derived from a levy on the salary (£600) of each deputy. In 1910, the last general election prior to the war, the party polled 1,125,877 votes, and returned 76 members. In 1912 no less than 282 communes (towns or villages) were controlled by a socialist majority of elected councillors, and in all 5330 socialists were successful at municipal elections. One outstanding personality must be mentioned. Jean Jaurès (1859-1914) began his career as a university professor of philosophy, and was first elected in 1885. His participation in the Dreyfus case made him known outside France, and from that period his magnificent eloquence, his energy, and his fine character made him not only the foremost of the socialists, but latterly perhaps the most powerful of French political leaders. His assassination in the first days of the war was an international calamity.

It is not possible in the space available to give many details of the socialist parties in the other countries. In Belgium there is a large and influential Labour party (*Parti Ouvrier*), which has united the trade unions and an extremely successful system of co-operative societies into an effective socialist party. Italy had a large party characterised by a series of internal discords like those of France, until it was for the time suppressed by Fascism. In Spain the socialists have been somewhat overshadowed by the anarchists, who, perhaps less numerous, are certainly more noisy. Norway, Sweden, Denmark, Holland, and Finland all have important bodies of socialists, which have in some cases polled more votes than any of their rivals. In Austria 83 members were elected in 1911, and out of 33 seats in Vienna 20 were held by socialists. There was also a large Christian Socialist party which apparently was based on anti-Semitism and was socialist (as well as possibly Christian) only in name. Russia we will treat of later on. In the United States the Socialist party was for many years excessively Marxist, and failed to obtain much popular support even from trade unionists. In Australasia socialism took a special form. In such 'new' countries government is the easiest source of capital for public undertakings, and is without the tradition of administrative nihilism which dies so hard in Great Britain. Therefore all sorts of commercial and industrial undertakings have from the first been organised by the Australasian States. In New Zealand the Liberal-Labour party under Richard Seddon, a miner by trade, gave a lead to the world by Women's Suffrage, Old Age Pensions, Compulsory Arbitration in Wages Disputes, and much else. In the Commonwealth, and in most of the States of Australia, Labour parties from 1904 onwards frequently took office, and carried out a policy which was practical socialism with little reference to theory. But it may be noted that in 1918 the Queensland government entitled an official report of its activities *Socialism at Work*. In later

years definitely socialist parties have made some progress in these dominions. Abyssinia, Afghanistan, the Central American republics, and, until quite recently, Ireland are about the only countries where socialism has not taken root.

The Socialist Organisation in Great Britain.—Throughout the Continent of Europe and the United States socialism from its beginning up to the war was predominantly Marxist, and followed the lead of Germany. In England and Australasia the movement developed on somewhat different lines. In 1881, H. M. Hyndman (1842-1921) founded the Democratic Federation; he was already a student, perhaps a follower, of Marx, but the federation did not become definitely socialist until in 1884 it changed its name into the Social Democratic Federation, commonly called the S.D.F. In addition to Hyndman, William Morris (1834-1896) and Mr John Burns were its best-known members. Its policy was Marxist, and great stress was laid on the Marxian law of value and on the 'Klassenkampf,' which is Englished into 'class war,' but more accurately means class struggle. It vigorous agitation soon attracted wide-spread attention and alarm, much of which was dispelled when the Federation ran three unsuccessful candidates at the General Election of 1885. Mr Burns polled 598 votes at Nottingham, but the two London candidates only obtained 27 and 32. In the same year William Morris left the federation and founded the Socialist League, a similar body which also carried on active propaganda, and ultimately moved towards anarchism. It lost all influence when Morris left it in 1890. The influence of Morris on the movement was profound. The S.D.F. taking their socialism from the bible of Marx, which was not published in English until 1886, was dogmatic and doctrinaire. Morris was accustomed to think for himself, and although he adopted the Marxian formulae, it may be taken that he hardly understood them and was not interested in them. What did interest him was the effects of capitalism on art and character. He loved the middle ages with their little towns, their handicraftsmen, artists as well as artisans, and their ordered life, free from the struggle for wealth amongst the few and grinding poverty amongst the many. Whether this view of the middle ages is historically accurate need not be discussed here. Morris wished to abolish all that the industrial revolution had created, and emphatically capitalist industry with its product, the vulgarity and ostentation of the rich capitalist, and the ill-paid routine labour of the poor. His extraordinary attractive character and world-wide reputation brought into the movement a large number of artistic and literary people, and gave to English socialism a breadth of view which it has never since lost.

The definite revolt against the intellectual tyranny of Marx came from another source. The Fabian Society, founded in January 1884, arose quite independently of Marx, and was based rather on the spirit of Henry George, who proposed to abolish poverty by legislative action, to wit, a tax on rent of land; and also on the positivism of August Comte. Begun in a very small way, it was promptly joined by a group of people who have subsequently become famous, amongst whom may be mentioned Mr George Bernard Shaw, Mr Sidney Webb, and for a short time, Mrs Annie Besant. They soon began to study *Das Kapital*, and came to the conclusion that the Marxian law of value was not economically sound, and also that the validity of the doctrines of socialism was in no way dependent on that or any other Marxian dogma. Land taxation they also rejected as an inadequate remedy. *Fabian Essays in Socialism*,

by seven leading members, an exposition of the principles of socialism from the standpoint of English political and industrial conditions, was published in 1889, and at once made an epoch in English socialism. By this time socialism had become notorious throughout the country. Trafalgar Square riots (1886 and 1887) and the Dockers' Strike (1889) together with a period of severe industrial distress, kept the socialist agitators constantly before the public, and when the new doctrine was published in language free from the obscurities of Marxian dialectic with its foreign vocabulary and revolutionary violence, the younger working class leaders welcomed it gladly. The Fabian Society never endeavoured to form a political party, but this political method was preferred by the working class agitators, with the result that in 1893 the Independent Labour Party was founded at Bradford by J. Keir Hardie (1856-1915). He was Secretary of the Ayrshire Miners' Association, and his eloquence, sincerity, and charm of character quickly made him a leader of men. He was elected in 1892 member of parliament for West Ham on independent lines, and except for an interval, 1895-1900, sat for the rest of his life. He served his society and the Labour party of which he was in 1906 the first parliamentary chairman, with unswerving loyalty, until his death in the second year of the war. The I.L.P. (as it is often called) designed as a Labour Party, soon became and has since remained, a strictly socialist propaganda society. It was from the first thoroughly English in its temperament, practical rather than theoretical in policy, conciliatory in methods, and above all, free from the anti-religious taint which hung about the Marxists. It made rapid progress in Yorkshire and Lancashire and later in the Midlands, Scotland, and in London. It attracted the younger leaders of the trade unions, and quickly obtained a hearing in the Trade Union Congress. It made a principal aim of inducing trade unionism to break away politically from the Liberal party, and in 1899 succeeded in getting the Trade Union Congress to decide on summoning a conference of trade unions and socialist societies for united political action. This conference met early in 1900 when the Labour Representative Committee was established, which six years later changed its name to the Labour Party. The S.D.F., the I.L.P., and the Fabian Society took part in this organisation of working-class forces, but the first-named withdrew in 1901. Mr J. Ramsay MacDonald (Prime Minister, 1923-24), was the secretary from the beginning. One other factor in the socialist movement should be named. The *Clarion*, a weekly newspaper, edited by Robert Blatchford, was founded in 1891, and for over twenty years exercised a strong influence, notably in the northern and midland industrial areas, and was specially successful in keeping the movement good-humoured. The *Clarion* was full of fun, and was connected with a whole series of allied organisations for cycling, dancing, &c. Always socialist, its teaching was the antithesis of the grim bitterness characteristic of most of the continental movements.

Between 1890 and 1906 the socialist movement made steady progress. The I.L.P. had branches in every city and, in the industrial counties, in almost every village. The Social Democratic Federation (or Party, as it was called later on) was less numerous and influential, but played its part with vigour. The Fabian Society, mostly middle-class, and largely recruited from the older universities, devoted itself to 'permeation,' that is, to working out the application of its principles to current politics, and persuading political parties and personages to carry them into effect. The

Marxists visualised socialism as a plan to be adopted 'on the morrow of the Revolution' when the old order had been swept away. Fabians held that socialism is a principle already moulding the structure of society and destined to do so increasingly in future decades. The Post Office and the Death Duties, Municipal Gas-works and Tramways, Factory Acts, Education Acts, Workmen's Compensation Acts, were all regarded as steps in the direction of the regulation of social life by the community in the interests of the whole. The individualism of the mid-Victorian Radicals was already a thing of the past. The Charity Organisation Society had become a voice crying in the wilderness for self-help, and Mr Harold Cox was almost its only echo.

In 1906 the political world woke up with a start to the new order. The Labour party put forward fifty candidates at the general election in January, and twenty-nine were successful. It is true that the Labour party was not then avowedly socialist, but nearly all its leaders, most of whom were the secretaries of important trade unions, were actual members of socialist societies, and whilst it had no written programme, its policy was in fact always socialist. This is further indicated by the fact that its first chairman, J. Keir Hardie, was no longer a trade union official, but the leader of the I.L.P. The anti-socialist 'stunt' which immediately followed in the press, added to the membership and influence of the socialist societies; for although the maxim that 'the blood of the martyrs is the seed of the church' was not always true when persecution took the extreme forms not uncommon three or four centuries ago, it is certainly true of such mild methods as result from an English newspaper campaign. Keir Hardie, Mr J. Ramsay MacDonald, and Mr Philip Snowden, of the I.L.P., were now in the House of Commons, whilst amongst trade unionists, who were also socialists, may be named Messrs Arthur Henderson, J. R. Clynes, George Roberts, and G. N. Barnes, all subsequently cabinet ministers. By 1910 practically the whole of the principal trade unions had joined the party, which at the two elections in that year secured forty and forty-two seats.

Having described the growth of the socialist movement in Great Britain up to the beginning of the war, we must now turn back to take up again two threads dropped at an earlier point in this article; one concerns theory; the other organisation.

Syndicalism.—We have already described the origin of anarchism, and outlined its theory. It failed to convince all but a few idealists among the educated, and somewhat more of the natural-born rebels among the half-educated, because the economic methods of a Russian village will not work in a cotton factory or on a railway. Trade unions, natives of British soil, were almost unknown elsewhere till the latter end of the 19th century. In France they were only legalised in 1884, but thereafter they grew rapidly. Anarchism postulates a voluntary group of workers to carry on each industry. A trade union is such a group. That a trade union should own and manage a coal mine or a cotton factory is not perhaps a practical proposition, but certainly is a plausible suggestion, and in France as soon as trade unions became strong this idea rapidly gained ground. Syndicalism is merely the French word for trade unionism; and syndicalism is a proposal for substituting trade unions both for capitalists and for the capitalist state. Politics in France at this period were not in good repute; government was an affair of factions rather than parties, corruption was believed to prevail, and several prominent socialist leaders had gone over to take

ministerial office in the Republican party. Hence the cry caught on that workmen should adopt 'direct action' instead of politics; capitalism must be overthrown by incessant strikes; capitalists must be attacked by 'sabotage,' that is, by damaging machinery, spoiling finished goods, 'cut canny,' and similar measures. Then when the time came for the workers to seize the factories after a successful General Strike, the wearied proprietors would resign them with little reluctance. Followers of the popular philosopher Bergson, who placed instinct above reason, and impulse above plan, supplied the movement with an intellectual justification. The *Confédération Générale du Travail*, the French equivalent to our Trade Union Congress, constituted under that name in 1895, became the centre of syndicalism, but it must be remembered that trade unions in France were not then (or subsequently) so well organised, or so rich as those of Great Britain. In 1898 the income of C.G.T. was no more than £78. Syndicalism spread wherever anarchism had taken root, that is, in Spain and Italy, as well as France. It also obtained a footing in the United States, under a slightly different form, as the Independent Workers of the World, a fighting trade union commonly called the I.W.W. In England its career lasted for only two or three years, between 1910 and 1913.

The ideal towards which syndicalism looked was complete national government by trade unions. The existing state based on geographical franchise was to be replaced by a state based on occupational franchise. It was said that the trade in which a man passes most of his waking hours throughout his active adult life, is more to him than the street in which he happens to live, and that he has more in common with his fellow-workmen than with his neighbours. Hence the new idea of occupational franchise. Syndicalism involves industrial unionism, that is, the organisation of a single union for all persons engaged in one occupation, e.g. railways, mines, shipbuilding, instead of craft unionism, in which engineers belonged to one union, wood-workers to another, labourers to another, and so on. Craft unionism generally prevails in England, and it makes the acceptance of syndicalism difficult. But the vital distinction between syndicalism and socialism is that the one is an organisation of producers, the other of consumers. Socialism is based on the maxim 'production for use and not for profit.' As at present the municipality hires men to make gas, to run trams, to cultivate parks for the ratepayers who desire the product, so in the socialist state the citizen as consumer will employ the citizen as producer to carry on all forms of industry which are at any given time socialised. The objection to control of industry by producers is, that the producer is always conservative; he dislikes changes in the methods of production which diminish the value of his acquired skill, whether it be in composing Greek epigrams or working a hand-loom. And he also objects to altering the product; he prefers to go on making exactly what he has made before. On the other hand, the ideal of the older socialists, implicit rather than expressed in England, a universal state carrying on all industry through a hierarchy of officials, is not exactly alluring. Government is, in the opinion of most people, like the doctor, called in imperiously when anything goes wrong, but otherwise preferably rather in the background. Especially to the ordinary artisan and labourer, the difference to himself in his daily life between Woolwich Arsenal and Armstrongs is small although the one produces for, and is controlled by, the community, whilst the other produces for private profit. Hence the cry caught on that

socialism would lead to the 'servile state,' would be a bureaucracy no better for the average man than the present plutocracy.

Guild Socialism.—About 1911 a new set of ideas began to make itself felt. Started by a group of younger members of the Fabian Society, and advocated in a weekly paper, *The New Age*, guild socialism quickly attracted much attention both amongst political thinkers and in the ranks of trade unionism. It was a compromise between socialism and syndicalism. It proposed to revive the guild system which prevailed in the middle ages, to make trade unions, like the guilds, the authority for the trade with which they are concerned; but it retained the existing territorial state for all public business other than industry. There would be a guild parliament for the control of industry and a territorial parliament for other affairs. The guilds would pay rent to the state for mines, railways, land, and similar monopolies. The National Guilds League, formed in 1915 to advocate these ideas, was not a body of extensive membership, but the teaching of the guildsmen for a time found widespread acceptance. Mr G. D. H. Cole was their most important leader, and published numerous books on the subject. The 'self-governing' workshop has always been an idea attractive to middle-class philanthropists and political thinkers, and the self-governing guild found supporters amongst those who feared the 'servile state.' But a few years after the war one section of the guildsmen joined the Communist Party and another devoted themselves to establishing building and other 'guilds,' that is, bodies of trade unionists engaging in industry in competition with capitalist employers. These failed, as such schemes usually do, the National Guilds League broke up, and all that remained was a more general recognition of the claims of labour to a share in the control of any socialised industry.

The Second International.—The second thread which we have to take up in order to complete our account of socialism up to the war is the Socialist International. We have touched on the First International which expired about 1874. By 1889 Marxian socialism had gained a footing in most European countries, and in that year an international congress, or rather two congresses, met in Paris, out of which grew the organisation now commonly styled the Second International. Congresses followed in Brussels in 1891, Zurich in 1893, and London in 1896, and thereafter they were held regularly every three or four years up to 1910. The congress due in 1914 was fixed for September in Vienna, and, on the outbreak of war, naturally did not take place. The early congresses devoted much of their energies to expelling the anarchists who had got themselves sent as delegates in order to engage in controversy with the socialists. English trade unions were admitted, not because they were necessarily socialist but because it was held that a trade union is by its nature engaged in conflict with capitalism. Gradually a considerable international organisation was perfected. At first voting was by nations, and the one Greek or Argentine delegate counted as a nation equivalent to Germany or France. Latterly each nation was allotted votes according to scale varying from two to twenty. A permanent 'bureau' was established in Brussels, an executive committee held meetings every few months, and in each country there was a national organisation which also met to consider communications from or to the bureau, and to arrange for the quota which each nation contributed to its upkeep. In Great Britain the secretary of the Labour Party, the largest labour and socialist organisation, was the international secretary. As

far as Britain was concerned, the congresses of the international were important chiefly for the purpose of exchange of ideas. British trade unionists and socialists are accustomed to decide on their political policy for themselves, and are not greatly concerned with the views of other nationals. Continental socialists attach more importance to the resolutions of these congresses, as the following incident will indicate. Millerand, the French socialist leader, had joined the republican cabinet of M. Waldeck-Rousseau, and Jaurès had approved his action, thus splitting the French socialist party. The matter was debated at the Amsterdam congress of 1904, Jaurès leading on one side and Bebel on the other. Bebel secured a majority, and Jaurès bowed to the opinions of the Germans and other foreign socialists and withdrew his support of Millerand. A topic always discussed at international congresses is militarism. The Marxist view, accepted by the great majority of socialists, is that wars are always caused by capitalists, both for the purpose of extending their exploitation of non-European people and in order to make profit by the manufacture of munitions, the issue of loans, &c. Whether this doctrine, which no doubt has a kernel of truth, has survived the Great War is not yet clear. Socialists accordingly always protested against war, and a section, led by Keir Hardie, was anxious to make preparations for declaring a General Strike in countries about to be concerned in any war. The German party always opposed this plan, not because they objected to the principle, but because they foresaw that in Germany it would not be practicable. In 1912, when a European war appeared to be imminent, a special international congress was summoned at Basle for 24th November, and at a few weeks' notice 555 delegates, including 13 from Great Britain, met to record the protest of the socialist and labour movement of the world. A demonstration in the cathedral and a session of one day sufficed to register a unanimous verdict.

The war broke up the International, and its headquarters at Brussels were occupied by conquerors. During the war various meetings of socialist leaders were held with a view to formulating terms of peace, which attracted attention at the time, but had no permanent results. The rise of communism created an element of discord, but ultimately, in May 1923, a new Labour and Socialist International was formed at Hamburg at a conference attended by 424 delegates representing thirty countries.

The Third International, confined to communists under the leadership of the Russian Soviet Government, has been much discussed, but has not attained importance.

Before the war the socialists in the European empires were revolutionists confronting great military autocracies; elsewhere they were minorities with little hope of attaining power. Thus they had much in common, since their concern was the unknown future. The war replaced the three empires by a number of republics, and socialists since the British election of 1923 have nearly everywhere become political parties, and have held office or expect to do so. Their problems are no longer abstract and international, but concrete and national. The only country where socialism has permanently prevailed has shown itself hostile to the socialists of other countries, and its hostility is reciprocated. This demonstrates that the idea of the universal brotherhood of socialists was but a dream. Hence it is likely that international socialist congresses will in the future attract less attention than in the decades before the war.

Socialism in the Great War.—By 1914 there was

an important socialist political party in the parliament of nearly every civilised country except the United States of America, but everywhere they were a minority and in opposition. In the few days before the declaration of war the socialists, especially in Germany, took such steps as were practicable, by meetings, demonstrations, and newspaper propaganda, to advocate peace. But in such times political agitation counts for little. When the war was actually begun the socialist parties on the whole supported their respective governments. In Germany, at the start, it was generally believed that the war was really an attack on Germany by the hordes of half-savage Russians. After some hesitation patriotism prevailed, and the social-democrats, for the first time, supported the Kaiser's government. France and Belgium were attacked, and socialists there naturally rallied to the defence of their countries. Great Britain joined the conflict in defence of Belgium, and the Labour Party as a whole decided to support the government; a policy which it maintained until the armistice. Marxian socialists have never objected to fighting, as recent events in eastern Europe have shown, or to conscription, which they regard as the most democratic or equalitarian method of raising an army: they hold that the British method of hiring ill-paid labourers to fight for wages partakes more of capitalism than the continental plan of every citizen doing his share. On the other hand, the British I.L.P., which was never Marxist, had always opposed wars, as for example that in South Africa in 1900, and during the Great War its members formed the most prominent section of the pacifist party. They did not carry the Labour Party with them, and some prominent trade unionists left the I.L.P. on this question. In the United States and in the Dominions the socialist parties adopted more or less the same attitude. But it must be clearly understood that pacifism is not a generally accepted doctrine of socialism. The resolutions against militarism which have been so often carried at international congresses may be taken to mean no more than that socialists have the strongest objection to wars the purposes of which they do not approve.

The first effect of the war was enormously to enhance the importance of organised labour, which in England for most purposes may from this period be considered as identical with the essentially socialist Labour Party. In order to maintain production of necessities, to secure an adequate output of munitions, and to create an enormous army, the co-operation of the trade union leaders was indispensable, and the government accordingly consulted with them before any new measure affecting labour was adopted. Then came the Coalition, and Mr Arthur Henderson, the leader of the Labour Party, accepted office in the small war cabinet with the approval of his party. Later on he was succeeded by Mr G. N. Barnes, for many years the secretary of the Amalgamated Society of Engineers, and a socialist of even longer standing than Mr Henderson. The same policy was adopted in France, where M. Albert Thomas and two others, members of the Socialist Party, joined the government, and by the Belgians, for whom M. Vandervelde, standing chairman of the International Socialist Bureau, became a minister, and for a long period represented the Belgian cabinet in London.

The Russian Revolution.—We now turn to Russia, and must revert to an earlier period in order to complete the story. Although the leaders of anarchist thought came from Russia, it does not appear that an anarchist movement of any importance was developed there. Throughout the

last half of the 19th century a revolutionary agitation against the terrible tyranny of tsardom prevailed. It was known in the west by the name nihilism, which properly applied only to a small school of philosophical materialists. The revolutionary movement was of course political and not economic; every old nation has had a revolutionary struggle when autocracy was compelled to give place to constitutionalism. But in fact all the nihilists (as we may call them) were also socialists, or, in a few cases, anarchists. Refused all constitutional methods of reform, the nihilists resorted to assassination, and the government in return hunted them down, and punished by death or life-long imprisonment or exile to Siberia all who could be in any way implicated with socialist or anarchist doctrines. But the apparently hopeless struggle had more effect than was apparent. After the defeat of Russia by Japan, the demand for a Duma, the traditional Russian parliament, culminated in a General Strike of all trades and classes in October 1905, and the tsar gave way. The socialist parties refused to participate in the election of the first Duma in 1906, but in the second, elected in January 1907, out of 524 members 132 were socialists. The government soon reverted to repression, and during 1908 no less than 782 persons were executed for political offences, and 70,000 were exiled. The bureaucracy of Russia were sowing seeds from which a dozen years later they were to reap a terrible crop. Russian socialists were divided into two schools. The social-democrats, pure Marxists, who were nicknamed bolsheviks (meaning merely that at a certain decisive vote they were the 'majority'), believed that the evolution of society, as described by Marx, must even occur in Russia, where the bulk of the people are land-owning peasants, and therefore that no revolution could take place until these small landowners had in the inevitable economic evolution become landless proletarians. The other school, the social revolutionists, moderates in spite of their name, believed that the evolution of Russia would proceed on its own lines, perhaps on the basis of the quasi-communism of the Russian village community, the Mir. In March 1917 with the deposition of the tsar came the political revolution. Although the actual seizure of power was the work of liberals rather than of socialists, it soon appeared that the Social Revolutionary party was the only one ready to undertake the government, and A. F. Kerensky, a socialist barrister, became its head. In November his government was overthrown by N. Lenin (otherwise V. I. Ulianov) and Leon Trotsky, who had returned from exile to lead the Marxists. From this time onwards Russia has been ruled by this party, which calls itself the Communist party, whilst by others it is sometimes designated bolshevik. They endeavoured to govern Russia according to the teaching of Marx as they understood it; and they attempted the almost impossible task of carrying out a complete economic revolution concurrently with a political revolution in a country demoralised by centuries of autocracy. The communists have adopted a principle based on a phrase used, but not explained, by Marx in 1875, 'the dictatorship of the proletariat,' according to which, after 'the Revolution,' all other classes are excluded from power. By their constitution, therefore, only the workers are allowed to vote. This, of course, is inconsistent with the universal democracy which in the opinion of most socialists in all other countries is an integral part of their creed. What is called the soviet system of government is merely a very crude form of electoral organisation, by which (to use English terms) over the greater part of the country each parish elects a council; that council elects

delegates to form, with the delegates of other parishes, a district council; district councils in the same way elect county councils, and county councils elect parliament. In practice some soviet members appear to be elected by factories, which is a concession to syndicalism. There appears to be no Marxian authority for this plan of indirect election, which in fact had arisen spontaneously before the arrival of Lenin in Russia, and it may well have been the only practicable plan in such a country at that moment. It has the advantage to those in command of making the government in practice irremovable. The communists introduced, suddenly and universally, the industrial methods which most other socialists hope to reach in some industries by slow degrees. In 1918 the large industries were nationalised. In 1920 all enterprises employing more than five workers with machinery or ten without, were also nationalised by decree. But before this was carried into effect the disastrous results were so apparent that in 1921 a 'New Economic Policy' was adopted at the instance of Lenin, which reversed the process, first in respect of the smaller industries, and in 1923 in respect of the larger. A system of state-controlled trusts was then established for the management of big industry and finance, of which 426 had been formed by the end of 1922. Private property, which had been abolished in principle, was again permitted, and industry under the N.E.P. was carried on partly by the state, partly by co-operative societies, and partly by private enterprise.

Lenin died in January 1924, and since then Russia appears to have been governed by a self-appointed group of communist leaders, whose happily bloodless quarrels are not controlled by any really representative assembly. A description of the ruthless violence with which the communists established their rule, and any discussion as to its alleged necessity or justification, are both outside the scope of this article.

At the End of the War.—The defeat of Germany and the abdication of the Kaiser were followed in Germany, as in Russia, by the emergence of the socialists as the one party able to control the nation, and in Austria, in Hungary, and, in fact, in nearly all the new countries which sprang up on the ruins of the Austrian and Russian empires, the socialist parties were at first in control, though in some cases they retained power only for a short time. In Germany the majority socialists, who had supported the war, were attacked by various groups, more or less in sympathy with the Russian communists, and for some time disorder prevailed, in the course of which two leaders of the extremists, Karl Liebknecht, son of the leader of earlier days, and Rosa Luxemburg, were killed, some say murdered. Ultimately things settled down; the majority socialists were wise enough not to attempt to change the industrial system otherwise than by degrees, and they retained power until the election of 1920, at which they were greatly weakened by the 'separatist' tactics of the above-named dissentient groups, with the result that a coalition of other parties assumed the responsibilities of office.

Socialism in Great Britain after the War.—In 1918 the Labour Party for the first time formally adopted a definitely socialist policy. According to its constitution, its objects are to form a political labour party, to co-operate with the Trade Union Congress, and 'To secure for the producers by hand and by brain the full fruits of their industry and the most equitable distribution thereof that may be possible, upon the basis of the common ownership of the means of production and the best obtainable system of public administration and control of each industry and service.' In the 1918

election it ran 361 candidates, of whom only 57 were successful; but this result was a greater success than appears on paper, since in many contests the 'free' liberal was at the bottom of the poll, and as the Liberal Party won only twenty-eight seats, the Labour Party became the official opposition. The more prominent I.L.P. members who were pacifists lost their seats. In the election of 1922 the party won 142 seats; in 1923 it obtained 191, and with the assistance of the liberals defeated the conservative government by 328 to 236 votes. Mr Ramsay MacDonald thereupon formed a labour government, which held office, with liberal support, until defeated by the withdrawal of that support. A general election followed in October 1924, and led to the victory of the conservatives, who won 412 seats against 152 labour, 42 liberal, and 6 other.

With the attainment to office of the Labour Party, it may be said that socialism in England, as a sectional movement, came to an end. It began about 1883 as a number of thinkers and agitators who formed small propagandist societies; gradually it grew into a minority political party; in 1918 it became the opposition; in 1923 the government. As such it has become a constituent part of the history of England, and the successes and failures of the Labour Party are factors in the life of the nation.

It is therefore unnecessary to give details of the socialist societies since the war. The I.L.P. and the Fabian Society do their political work through the Labour Party, and are chiefly useful as organs for devising and popularising the application of the principles of socialism to the political and social problems of the day. The Social Democratic Federation changed its name in 1911 to the British Socialist Party, and in 1916, after many years of isolation, rejoined the Labour Party. Subsequently many of its members became communists, and the rest in 1920 reverted to their old name. Since the death of H. M. Hyndman in 1921, the S.D.F. has lost its importance.

The Communist Party.—A brief notice of this small but noisy party is necessary. Throughout the history of the socialist movement in England there has been a left wing, consisting of fanatic extremists, who denounce the majority as weak-kneed time-servers. In the 'eighties' they were anarchists. In the early years of the Labour Party the Social Democratic Federation and its successor, the British Socialist Party played the part. Then came the guild socialists, and the last phase is the communists. In many cases the people are the same, though the battle-cry has been changed.

Communism differs from the other left-wing movements in that it is closely connected with a foreign government. It takes its ideas and its orders from Russia, and, what is more, obtains funds from the same source. Hitherto it has been a healthy factor in all forms of popular agitation that the money available was roughly correlated with the number and devotion of the adherents. The law of the survival of the fittest operated. Only those movements could go on which were able to obtain substantial popular support. It is another matter when a small group in any country is subsidised by a foreign government. Such success as communism has had is not necessarily due to its merits, but may be attributed in part to Russian gold. The communists desire to affiliate to the Labour Party in order to use its platform for advocating their own policy, but their admission has been refused by enormous majorities, and individual communists are not allowed to join the Labour Party directly. Indirectly, as members of affiliated trade unions, they cannot be excluded.

In 1925 the leading communists were convicted of sedition, and sentenced to imprisonment. Many

members were imprisoned or fined for violent speeches during the miners' lock-out of 1926.

In Germany, France, and other European countries the communist parties have attained considerable electoral strength, and division into two hostile sections has everywhere weakened the effective force of socialism.

The Policy of Modern Socialism.—It remains to describe socialism as understood by its adherents in England. Let us first state what socialism is not. In a Report to the International Congress of 1896, prepared by the Fabian Society, that society states that 'it has no distinctive opinions on the marriage question, religion, art, abstract economics, historic evolution, currency, or any other subject than its special business of practical democracy and socialism.' In the 19th century the early German and other socialists attacked both religion and the existing form of marriage. But it was soon recognised that these subjects had no necessary connection with socialism, and, in fact, socialists as individuals hold different opinions about them. In England no socialist party of any consequence has adopted a policy on religion or marriage.

The constitution of the I.L.P. states that it is a socialist organisation, having for its object the establishment of a socialist commonwealth—that is, a state of society in which land and capital are communally owned, and the processes of production, distribution, and exchange are social functions. The I.L.P. believes in democracy organised, both in its political and industrial aspects, for communal ends. Political democracy is defined as practically the existing system of central and local government, apart from the hereditary elements of the former: industrial democracy as the organisation of producers and that of consumers. Each industry should be managed by representatives of those engaged in it, together with representatives of organised consumers, and a central body representing both sides should control production as a whole. The immediate objects of the I.L.P. include assisting trade unionism and the co-operative movement. It is opposed to war, imperialism, and the exploitation of native races.

The basis of the Fabian Society, as revised in 1918, says:

'The Fabian Society consists of socialists. It therefore aims at the reorganisation of society by the emancipation of land and industrial capital from individual ownership, and the vesting of them in the community for the general benefit. In this way only can the natural and acquired advantages of the country be equitably shared by the whole people.'

'The society accordingly works for the extinction of private property in land, with equitable consideration of established expectations, and the due provision as to the tenure of the home and the homestead; for the transfer to the community, by constitutional methods, of all such industries as can be conducted socially; and for the establishment, as the governing consideration in the regulation of production, distribution and service, of the common good instead of private profit.'

The Labour party has a much fuller programme entitled 'Labour and the New Social Order,' adopted by the party as a whole at a conference held in June 1918, before the end of the war was actually in sight. It may be taken to be an exposition of the aims of the socialism which is the policy of the British party, moderately worded, but accepted by all sections of the party and therefore authoritative. Its authorship is commonly ascribed to Mr Sidney Webb, who became a member of the Labour Party executive in 1915, and was elected at the head of the poll in 1919. It should be said that modern socialism owes more

to Mr Webb than to any other thinker since Marx. The constructive socialism formulated by the Fabian Society is largely his work, and his numerous books, mostly written jointly with his wife, contain implicitly or explicitly nearly all the ideas which differentiate British from Marxian socialism.

'The Programme of the Labour Party on Reconstruction' (this is the sub-title) begins by stating that 'Society itself' must be reconstructed. It was foreseen months before it happened in Central Europe that the war was 'the culmination and collapse of a distinctive industrial civilisation.' 'Capitalist production' and all that it involves 'have received a death-blow.' The new social order must be based on production and distribution 'for the benefit of all who participate by hand or by brain.' Four main objects are specified: '(a) The universal enforcement of the national minimum; (b) The democratic control of industry; (c) The revolution in national finance; and (d) The surplus wealth for the common good.' The first is the securing to every member of the community in good and bad times alike of all the requisites of healthy life and worthy citizenship. This involves the principle of legally prescribed minimum wages and the prevention of unemployment. Democratic control of industry must be based on the common ownership of the means of production, with the immediate nationalisation of railways, mines, and electricity. In agriculture the future is seen in a combination of national farms, small holdings, municipal enterprises, and farming by consumers' co-operative societies. In finance, taxation of the wealthy by extension of income-tax and super-tax, and a capital levy to pay off the debt or part of it. Ultimately the surplus wealth above the standard of life must go, not to the senseless luxury of the idle rich, but to common good. For the wise carrying-out of these plans the Labour Party looks to the scientific investigation of each problem, deliberate organisation of research, and in all fields of life, democratic co-operation. This is a brief summary of a pamphlet of 24 pages.

A Constitution for the Socialist Commonwealth of Great Britain.—The socialist movement has always been weakest on the side of reconstruction. The majority of writers and speakers find sufficient scope for their energies in describing the evils they see in existing institutions, and advocating their prompt abolition. The wiser thinkers have been discouraged by the complexity of the problem, and have put their trust in the maxim *solvitur ambulando*. The only serious forecast of the future under socialism is a volume with the above title written by Mr and Mrs Sidney Webb in 1920. This deals in the first place with central and local government, subjects on which we must not embark, beyond stating that the authors propose that there be two parliaments, one dealing with politics, in the Victorian sense of that word, and the other with social and industrial matters. No catastrophic change is contemplated, but rapid progress on existing lines, that is, the transfer of one industry after another from private ownership to the central or local state, and the gradual abolition of 'living by owning' by means of taxation and death duties. Compensation must be given for each particular industry or piece of land taken over, as at present, but the wealthy as a class must bear the taxation necessary to pay interest on and redeem the debt thus incurred. Consumers' co-operation is regarded as a permanent part of the future state, and its wide extension anticipated, until it takes over virtually the whole supply of common household requisites, and perhaps a good deal more. The authors assert 'that there is no reason to assume that in the socialist commonwealth every adult

citizen will be engaged, at salary or wages, in some vast administrative machine. . . . There is nothing in socialism that requires or even makes probable the suppression of the independent craftsman or brain-working practitioner. Each vocation must have the right of self-determination, but must be in the last resort subject to the social parliament. As for private property, socialism will enormously increase it. The fault of the present system is not excess but defect in private property. The vast majority of families possess far too little, and many of them virtually nothing at all. Socialism will put an end to most of the private ownership of the means of production, but it will increase private property in the home and homestead, the paraphernalia and the hoard, involving all the amenities of life. Finally, it will replace the passion for riches, which capitalism has regarded as the master-motive, by the spirit of service, which already animates some of the professions, and must ultimately dominate industry as well.

Such in brief outline is the forecast of Mr and Mrs Webb. All socialists are persuaded that socialism in some form is the hope and the certainty of the future. Whether it will come about in Great Britain in the orderly and peaceful way anticipated in the above-named volume depends, as socialists think, on the spirit in which the claims of the workers are met by the possessing classes.

Societies are associations for some particular object, such as the promotion of science, art, and literature; the diffusion of knowledge, religion, and morality; intercourse between those of the same profession or trade; the removal of legal grievances; mutual aid in case of distress; and an abundance of other aims, which are either beneficial to the general public or to the members of the society alone. The great scientific, literary, and art associations are many of them separately treated in this work (see **ROYAL SOCIETY**, **ROYAL ACADEMY**, &c.). So are many special institutions like the Humane Society (q.v.), the S.P.C.K. (see **CHRISTIAN KNOWLEDGE**). Others are dealt with in the articles on the subjects with which they concern themselves (**LIFEBOAT**, **TEMPERANCE**, &c.). In Britain the term academy is usually reserved for art associations; but on the Continent the great national literary and scientific organisations are usually styled academies, and are treated at the article **ACADEMY**. See also **BOOK-CLUBS**, **SECRET SOCIETIES**.

Society Islands. See **TAHITI**.

Socinus, the name of two celebrated heresiarchs, uncle and nephew, who have given name to a sect of Christians, the Socinians, whose doctrines, though by no means identical, are to a large extent those of the modern Unitarians.—**LÆLIUS SOCINUS**, or **LELIO SOZZINI**, was born in 1525 at Siena in Tuscany, of a family long distinguished for its cultivation of literature and science. He soon displayed a strong preference for theological inquiry, and in order better to prosecute his biblical studies made himself familiar with Greek, Hebrew, and Arabic. He became a member of a secret society formed in 1546 at Vicenza for the discussion of religious

questions. The conclusions arrived at were unfavourable to the dogma of the Trinity, held to have been borrowed by the early church from the speculations of Greek philosophers. The society was discovered and broken up, and among those who sought safety in flight was Socinus, who travelled in France, England, Holland, Germany, and Poland, and finally settled in Zurich, where he died in 1562. Lælius Socinus, unlike most heretics, was a modest and reticent man. He united in altogether unexampled degree the warmest piety with complete freedom in theological speculation, though this brought upon him the disapproval of Calvin—See Illgen's *Vita Lælii Socini* (Leip. 1814), and *Symbolæ ad Vitam et Doctrinam Lælii Socini* (Leip. 1826).

FAUSTUS SOCINUS, or **FAUSTO SOZZINI**, nephew of the preceding, was born at Siena, 5th December 1539, and lost his parents while still young. After visiting Lyons and Switzerland, he entered the service of the Grand-duke of Tuscany's sister in 1563, but in 1575 retired to Basel, to prosecute his theological studies more closely. Three years later he set out for Klausenburg, at the request of George Blandrata, whence next year he went to Poland. Anti-Trinitarianism was even stronger there than in Transylvania, and Socinus soon obtained enormous influence, insisting that Christ was to be worshipped and invoked in prayer (for the *adorantes*, and against the *non-adorantes*), that the only solid basis on which Protestantism could rest was human reason, that everything that contradicted it should be rejected as false and incredible, and that dogmas that were absurd should not be allowed to shelter themselves from criticism because their defenders chose to call them mysteries. The Protestants were alarmed, and the ablest among them undertook publicly to confute Socinus. A disputation was held in the college of Posna, which ended in Socinus reducing all his opponents to silence; but they retaliated after the unscrupulous fashion of the times by trumping up against their vanquisher a charge of sedition, which, although ridiculously groundless, made it necessary for Socinus to withdraw from Cracow. While living in retirement on the estate of a Polish noble, Christopher Morsztyn, he married the daughter of his protector. In 1588 he took part in the synod of Brest (on the borders of Lithuania), and combated all the principal dogmas of the church—the divinity of Christ, propitiatory sacrifice, original sin, human depravity, the doctrine of necessity, and justification by faith. In 1598, on the publication of his *De Jesu Christo Servatore*, his enemies stirred up the populace of Cracow against him; and Socinus was torn from a sick-bed and nearly murdered. Soon after, he left the city and found a refuge with one of his friends in the neighbouring village of Luclawice, where he died, 3rd March 1604. The doctrine of the Trinity, Socinus held to be contrary both to Scripture and to reason, and the Old Testament to have a mere historical value; predestination was abhorrent to him, while communion became a symbolic act. He believed strongly in the immortality of the spirit (but not of the flesh). He drafted the Racovian Catechism, used as a confession of the Socinians. Racow (q.v.) was for long their main centre, and seat of their college. A Roman Catholic reaction, however, set in, and in the reign of John Casimir (1648-68) Socinianism in Poland received its death-blow, but it continued to flourish in Transylvania to the 20th century.

See Przypkowski's *Life*, prefixed to a collection of the works of Socinus in the *Bib. Frat. Polonorum* (Amst. 1636; Eng. trans. 1653; new ed. annotated by Sharpe, 1912); Bayle's article in the *Dictionnaire*; Toulmin's *Memoirs* (Lond. 1777); Fock, *Der Socinianismus* (1847); a *Life* by Wallace (1850); A. Gordon, *The Socinians and their School*.

Sociology. The latest and most complex of sciences, sociology (the systematic study of human affairs), has, so far, attracted but few workers and teachers. Naturally, therefore, it lacks as yet that general agreement as to methods, results, and aims which, in other sciences, is the active agent of their advance. Nevertheless, anyone may intelligently, and even productively, begin social studies. Most simply, one may begin by realising that, since the very origin of language, people have been thinking and talking about their affairs. And what are 'affairs' but, in essence, a moving sense of communion with the society around us? Of old, no doubt, people conceived their affairs in relation especially to their family or horde, their tribe and larger grouping. And, incidentally, it is a useful sociological exercise to observe and reflect upon the persistence with which these primitive social perceptions survive, under disguises and modifications, in the complex societies of to-day. A similarly primitive, yet also contemporary, social process runs perennially from home to hamlet, and onwards to neighbourhood, village, town, embracing also the corresponding region, and readily extending to country and empire. The human and the geographic notes are always blended in this primary social attitude. And some sense of relations, friendly or hostile, with others beyond, inevitably emerges.

For simple examples of the social relations manifest in each and every grouping, take those existing between children and parents, or between workers and their employers; and, for more complex instances, those between state and church, or between nation and nation. These relations are partly material and economic, but also mental and moral. Hence arise the rich human interactions named morals, manners, customs. And each of these pervasive types of social interplay may carry a weight of authority not less than that of written and codified law. Every human group, however modern and complex, has thus its ways of living, its '*mores*' (Fr. *mœurs*) or 'folk-ways'; so that the archeology of primitive man, the anthropology of savage or barbarian peoples, and the scrutiny of contemporary civilisations are studies fundamentally similar. Yet as these studies are pursued concretely, a great variety of specialisms arises, comparable to those which so long prevailed, and indeed must so far always prevail, among botanists and zoologists surveying their protean abundance and variety of life. And as these many specialised studies of organic beings have long been yielding a general science of biology, with its essential inquiries and results more or less common to all things living, so the concrete students of human societies and their ways are also searching to elucidate such general order as may be found through all forms of social life. There is therefore emerging a sociology which meets the requirements at once of observant and reflective minds. It inquires into man's ways of life in past and present, and strives to classify and interpret them as intelligible processes of social life. It not only searches into origins, but also estimates tendencies, and therefore peers into the future; for the social life it studies is in course of evolution. But evolution is not necessarily progressive. The evolutionary study of organic species shows them subject to arrest or decline, and even to extinction. So for human societies the same retrogressive processes are observable and have to be interpreted.

How can we define the relation between the recondite sociology of science and the unconscious sociology of plain folk? Well, admit that from simplest childhood to utmost age we are all of necessity interested in the society around us; assuredly it follows that to develop this common and natural interest to fuller understanding, and even to elicit

vital contribution, is an essential aim of sociology. Through its many portals we may advance from everyday experience to specialised knowledge, and yet integrate both towards social synthesis. Everyone, for instance, can realise how largely our yesterdays have determined to-day, and also that to-day has some range of freedom, some bearing on to-morrow. From observation and intelligence in the present, we thus look back into the past, calling in aid its biographies and histories. Some sort of sociology, however naïf and uninformed, we necessarily contrive for ourselves, as an aid to understand and interpret our arena of social affairs. The simplest occupations, the widest activities of life, have alike their sociological interest. Each day's work is normally of life-sustaining value; and this aspect of affairs can be viewed more and more widely in terms of the specialised studies, called by the learned political economy and speculative politics, each but a subdivision of sociology. And again, from house-door or garden-gate, we open into a widening world of social geography. Our interest in immediate neighbours may lead to ethnography and anthropology; and our friendships, our dislikes, are obviously psychological and even moral. And manifestly all these studies, from social geography through anthropology and psychology to ethics, are specialised approaches to one unifying study of social life in all its varied activities. In short, just as M. Jourdain talked prose without knowing it, so everyone, alike the plain man, the ardent specialist, and the critical philosopher, talks and thinks sociology, even though he may scorn that term or remain ignorant of its very existence.

In sociology, as in other sciences, the beginner tends first to follow a congenial leadership. In most cases the choice is from some specialised line of study, and generally there results a sociology of corresponding bias. Witness, for instance, the sociological pretensions of economists, from the Physiocrats to Adam Smith and onwards, one way through Ricardo and another through his anti-thesis Marx, to the comprehensive claims of their contrasted successors in the present. Others, following the lead of history, are at first necessarily limited to some nation or people, religion or period. Yet such workers collectively are building up a world-history which tends to push further and further into the past. And reaching beyond the limitation of annals, the inquiring mind reflects upon the significance of chronicled events; and hence arise philosophies of history, which seek also to understand the mentalities, the views of life, the 'social representations,' which underlie material events, and which by turns inspire them or result from them.

Similarly might be traced the enlarging surveys and amplifying interpretations reached from other specialised approaches, whether starting from the side of elaborated knowledge or of everyday experience. Their complementary products accumulate through the succession of generations, mingle into systems of thought, and generate customary attitudes towards life. Thus arises in each civilisation a tangled mass of survivals—moral, intellectual, and æsthetic. This ever-growing accumulation of experience, ideas, and ideals is the social heritage. Besides our organic heredity, and our material inheritance from the labours of the past, we are thus endowed with an immaterial and spiritual heritage, our body of social tradition. Its 'filiation' with the past is transmitted primarily by means of language; and manifestly with greater completeness and endurance through that invention of written records, which conspicuously marks the advance of barbarism into civilisation. By the interweaving of different social heritages the pattern

of every civilisation is shaped. However isolated or conflicting, all civilisations can thus be viewed as efforts towards unity. For are they not potential acts in an impassioned drama of creative humanity, waiting to be played upon the stage of our planet? This long-delayed consummation comes nearer, as sociology advances the knowledge and interpretation of all social formations, all civilisations.

To take some simple illustrations of the resources increasingly available to this end. Social knowledge aids the understanding of the current events we scan daily in our newspapers; it confirms or modifies their interpretations submitted in leading articles. Illuminated by history it may direct the statesman's conduct of affairs, external and internal. Fortified by experience it may guide the citizen's action. Enriched by altruism it may ennoble the plain man's life. In order to perform these services, sociology must incorporate into a working synthesis all the relevant knowledge available, and must adapt that synthesis to every-day usage. It must, for instance, assimilate historic annals, from far beyond Thucydides, once called the Father of History, and also their interpretations, from earliest sacred books to latest speeches. It must, for another example, incorporate economics from simplest food-gathering to world conditions and their adjustment. By means of observational and interpretative surveys, it must extend its domain throughout laws and politics, religions and philosophies, languages, literatures and arts. In all these respects the advance of sociology is dependent not less, but more, than the other sciences upon interaction with practical needs. As physical science alternately learns from industry and makes discoveries which promote inventions; as biological science draws from medicine and agriculture, and increasingly advances both; so a living social science not only learns from current events, but looks forward, with informed imagination, towards useful applications in social guidance. Examples of past endeavours might be drawn from codes of law and systems of religion, which coming down from ancestral tradition, survive by actual or professed adaptations to current needs. And in this process of adjustment a formative part is played by adventurous social thinkers who fashion their desires and hopes into inspiring presentments. Plato's ideal *Republic*, and Augustine's *City of God*, the Utopias of More and his modern successors, are all of them endeavours towards an ordering of affairs, which may be viewed as anticipations of an applied sociology.

There is thus ample scope for every mind to develop sociologically, from simplest observation of surroundings to furthest inquiries into the past, and highest aspirations towards the future. Manifestly no particular path is sufficient in itself; and experience shows that, since the present is so much conditioned by the past, and the living are so much governed by the dead, we must survey the present and interpret the past, before trying to forecast the future. Yet prevision is the highest goal of every science. And, in foresight of the future, sociology has to make good its scientific status. But significant distinctions emerge. From astronomy to meteorology, physical science foresees the future as unconditioned by human effort. But in the biological sciences, foresight goes with increasing control of the future, as in applications to agriculture and medicine, to hygiene and education. And social records show also examples of this combined foresight and control in deepening thought and enlarging statesmanship. It is evident, indeed, if not immediately, yet, on reflection, that the increasing complexity of things from the physical, through the organic to the social, is accompanied by increasing powers of control, *provided our knowledge of tendencies be adequate.*

And it is essentially to unveil, interpret and estimate, current tendencies that the sociologist surveys the present as quick with survivals of the past, yet also big with events of the future.

So vast a sociological programme affords room for specialists without number; and its comprehension seems far beyond individual powers. Yet in every period of science generalising minds appear, and accelerate the advance of order upon chaos in each field of enlarging knowledge. Witness the mastery of mathematics through its all-embracing notations; the advance of physics with the doctrine of energy; and the increasing grasp of biology in terms of evolution. But all the sciences are fundamentally one, and the rate of progress in late-comers depends largely on the use they can make of their predecessors. Thus, for instance, as physical science subserves physiology, so biological studies of organic life in its nutrition and reproduction, its self-maintaining and its species-continuing activities, and of life in general as interaction of organism with environment, throw light upon the like processes in human society. For every human society is confronted with the organic problems of its maintenance and continuance. And as the development of every species proceeds through its interaction of organism with environment, so we are bound to assume does the development of a people proceed through interplay of their life-work with its place. Again, the biologist contributes to social science when he studies the interaction of hunger and love in man regarded as the dominant species of the organic series. But the concepts of struggle and selection, thus passing over from biology into sociology, submit, under influence of the social heritage, to modifications, which out-range biological criteria. Physical science also aids directly, as in interpreting our human activities in terms of the energy and matter with which they are so largely concerned, either towards conservation or dissipation. The mathematician renders a fundamental service to the social sciences as statistician; as in compiling the census, constructing life-insurance tables, and very conspicuously in those pecuniary notations which have attained such significance throughout social life, even to dominating what seemed not so long ago the main field of political economy.

We have now outlined the spontaneous origins of sociology, or in other words, its elementary beginnings in every active mind. We have indicated the course of its natural growth and future prospects as culminating member in the circle of the sciences. It is time to turn to the historic facts of its formal origins, definite constitution, present state and precise requirements for prospective development as at once a natural science and a humanist study. But for final emphasis let us repeat the gist of what has been said. It is this. Starting as plain folk, more or less interested in human society around us, we advance towards sociological competence in the measure that we become students and searchers, by turns acquiring increasing knowledge of facts, and increasing command of them, through such order and progress as we can discern. Here the slogan of advance is, 'everyman his own sociologist.' And to that end we may consult articles like History, Geography, Political Economy, Anthropology, Folklore, Jurisprudence, Religion, Psychology, and Politics, with lesser references and biographies. But sociology, like other sciences, has a history of fairly definite origins and well-marked stages of advance. It has, in short, its precursors, initiators, and continuators. With these a working acquaintance is necessary for the serious student. Of innumerable precursors two stand out conspicuous. First came the Italian Vico, whose *Scienza Nuova* (1725) was sociological

in everything but name. And the same may be said of Condorcet's *Esquisse d'un Tableau Historique des Progres de l'Esprit Humain* (1794). Vico in his 'new science' offered an interpretation of history, which boldly sketches a naturalistic view of social development in religions, laws, and governments, running its course through a recurrent cycle of phases. First comes the 'age of gods,' next the 'age of heroes,' and finally that of 'men.' The first of these phases is patriarchal and theocratic; and the next is patrician and plebeian (but fundamentally aristocratic); and it passes into the third phase of the cycle, that of increasing democracy. Law, for instance, is first sacred and ceremonial, then is expressed in solemn formulae, and finally in terms of natural rights; while its judges are first conceived as gods to be supplicated, next as a high senate, and at length as the arbiters of authorised tribunals. Great religions, each with its mythos, doctrine, and ritual, rise, change, and fade; and kings, at first divine and heroic, next lose their odour of sanctity, then diminish in political significance, and finally, reduced in moral stature, they sink into decorative appendages or disappear. This endeavour of Vico towards a 'new science' attracted little notice at the time, and has failed to win critical attention since; but to-day we witness something which is almost a fashion, amongst the learned, for the cyclical view of history (as notably in Oswald Spengler's *Decline of the West*), but, so far, without reference to the originative work of Vico.

Condorcet's interpretative outline is more concrete than Vico's, and indeed comes very near to current views established in anthropology and culture history. He shows us, in the social dawn, family and horde living crudely by hunting and fishing, yet inventing language. Next appear the pastoral and nomadic beginnings of civilisation, with development of property and the rudiments of art and even science, of wealth and communications. All these endeavours towards civilisation are increasingly expanded in the next formative stage, that of agriculture. In his view of social development Condorcet emphasises Greek civilisation and culture, its philosophy and science, its literature and art, all taken in conjunction with the evolving law and extending empire of Rome as the historic matrix of modern civilisation. He depicts the mediæval order as retrogressive because lapsing from the classical culture. Next is valued the Renaissance for its recovery of the classical culture, and its development of that intellectual and moral heritage towards culmination in the science and philosophy of Descartes. Finally, in Condorcet's philosophy of progress comes his interpretative view of the revolution, in which he himself participated so dramatically both as agent and spectator. From the endeavours and aspirations of this upheaval—the Great Revolution, as French historians term it—he formulated those democratic ideals of progress towards an ever-brightening future, which, during the 19th century, animated the doctrine, and directed the practice, of the finer and more informed Liberalism throughout the western world.

From this late 18th-century revolution—in France mainly political, in Britain emphatically industrial, and in Germany predominantly intellectual—there issued, in the succeeding generation, many tentatives towards reconstruction in thought and action. In England, the most familiar is that growth and popularisation of economic doctrine, which later underwent a fissiparous division into rival schools, respectively classic and socialist. But for sociological initiative, other post-revolutionary developments are more significant. Notably so is that rich and varied counter-revolution which, going back on the cold intellectual classicism

of the 18th century, revalued the Middle Ages as an impassioned endeavour towards a civilisation founded on mercy and love no less than on truth and justice. Of the resulting movements many, to be sure, were filiated to the counter-revolution only indirectly or even unconsciously. Romanticism in literature and the Gothic revival in art, for instance, were without deliberate political or social aim. But the ultramontanist of the Continent, built upon doctrines expounded in Joseph de Maistre's great work, *Du Pape*, deliberately sought to infuse the political and social world with mediæval ideals of public action and private conduct. Pale reflections of this thorough-going Continental endeavour to reconstruct society on a more religious basis are exemplified by the Oxford Movement in England and the Disruption in Scotland.

The revolution and the counter-revolution are doubly significant for sociology. First, because they are active and expanding movements in contemporary civilisation; and next, because the endeavour to harmonise them, by uniting the intellectual and practical idealism of the one with the emotional and æsthetic appeal of the other into a single efficient instrument of social progress, affords a main clue to the life and labours of Auguste Comte. Through science Comte hoped not only to integrate complementary movements of post-revolutionary reconstruction, but also to correct their respective deficiencies by an appreciative incorporation of every historic initiative. Yet science must first unify itself into a well-knit body of doctrine at once naturalist and humanist. And for that synthetic purpose Comte affirmed the need of a culminating order of science, specialised upon man and his world, past, present, and future, yet so generalised in respect of all the other sciences as to bring their body of verified knowledge to bear upon the understanding and better ordering of human affairs. It was this crowning science that Comte sought to establish under the term sociology. He explained the hybrid origin of this new word as uniting the logical scientific spirit of Greek culture with the wider social order of the Roman world. For the word itself, therefore, he claimed justification on the ground that its etymology exposed the main historic bases of modern civilisation.

What, then, are the master conceptions on which Comte reared the structure of his new study, at once a science and a philosophy, a history and a doctrine? First, a regulative idea recalling Vico's, that of a progress of social thought through distinguishable stages. These he termed theological, metaphysical, and positive; and his disciple, John Stuart Mill, less controversially described them as volitional, abstractional, and scientific. For familiar instance take the interpretation of striking natural and social occurrences, such as lightning and epidemics, first, definitely, in terms of divine volition, as, respectively, thunderbolts and punishments; next abstractly and vaguely, as operations of nature; and at length, in terms of science, as electrical and pathological respectively, and thereby related definitely to the wider categories of, in the one instance, weather, and, in the other, disease. In the first or volitional stage, the explanations in terms of religion fail to satisfy inquiring minds, since devoid of suggestion for further research. In the next historic phase the abstractions offered, though of metaphysical impressiveness, have lost the previous completeness and simplicity; and so afford no effective interpretation at all. But in the third phase phenomena are freely submitted to that methodic search and experimental test which give them place within the expansive system of verifiable knowledge. But what precisely is this system of knowledge called science? How did it arise? What is, or should be, its relation

to the outer world of affairs and to the inner life of emotion and ideals?

To answer these questions was for Comte the necessary condition of equipping the barque of science with prow and helm. His sociology was designed for that double rôle. He demonstrated the need for a new science of sociology by pointing to the order (at once historic and logical) in which the larger groupings of science had grown towards maturity. First, because dealing with phenomena in their simplest aspects (i.e. most generalised and least complex) came the mathematical group (with astronomy as appendage). Next in natural sequence, as dealing with phenomena in an order of decreasing generality and increasing complexity, came first the material sciences (physics and chemistry, with their own specialised studies and integrating philosophies); and thereafter, at a considerable interval, the definite organisation of the life-sciences common to the plant, animal, and human world. But these life-sciences, even if extended (as Comte desired) to include psychology, manifestly do not exhaust the remaining field of knowledge open to the march of methodic research and experimental test. There remains, for conquest by scientific advance, the most complex and least generalised aspect of phenomena, viz. the world of social affairs.

And this fully human world, being by its very nature most modifiable in the scheme of things, would, if brought within the domain of science, be most open to scientific direction. Such was Comte's argument for claiming that sociology, once established, could and should yield guiding principles for systematic application of the whole body of science—material, vital, and social—to the enhancement of human life and the betterment of its environment. For this high purpose sociologists should, said Comte, deliberately prepare themselves. Two kinds of theoretical studies he indicated as essential. One was a grounding in each of the main groups of the 'preliminary sciences,' which was Comte's phrase for mathematics and astronomy, physics and chemistry, biology and psychology. The other imperative requirement was a grasp of history in all its essential aspects. The avenue to the first of these two preparatory achievements was manifestly open to studious ardour. But as to the essentials of history, what are they, where to be found, and how to build them into the structure of the new science? To the solution of these enigmas Comte devoted the master effort of his constructive genius. He reviewed the historic accumulations of his day, and rearranged their records and interpretations into a consecutive and ordered presentment of western civilisation conceived as the central drama of man's unfolding life and purpose. In his re-reading of history he applied two main clues. One was his 'law of the three states' (volitional, abstract, scientific); and the other his generalisation of the standard concepts, state and church. Borrowing from Catholic doctrine, he took the correlative phrases temporal power and spiritual power, and adapted them to his purpose. That, to be sure, is no more than doing for science what Dante, some five centuries earlier, had done for poetry. Let us conceive, said Comte in effect, every society, while it is alive and active, as a full-orbed community of two hemispheres, its temporal power concerned with material things, and its spiritual power with their non-material aspects. With these twin concepts of social structure and function Comte proceeded to his reinterpretation of all historic phases—past, present, and prospective—as a continuing interplay of temporal and spiritual powers. But historic change takes place, for better or worse, through the agency of representative men and

women. On the stage of each and every social formation we have therefore to search for the actors, who, because they are at once personalities and types, take the leading parts in their contemporary drama of temporal and spiritual powers.

A working classification of social types is here needed. To this problem Comte proposed, as an approximate solution, a fourfold classification. In the temporal power, characteristic of each successive phase throughout history, he distinguished its directive types as 'chiefs' from its operative types as 'people.' In the corresponding spiritual power he distinguished its more contemplative or reflective types as 'intellectuals' (religious, philosophic, scientific, poetic, artistic) from its more active and expressive types as 'emotionals.' These are the four social types Comte discerned as renewing themselves, under modifications adapted to the 'spirit of the age,' in each successive period of history. His 'chiefs' and 'people' are easy to grasp in their representative significance as perennial types. They are, for instance, in the language of to-day, capitalists and labourers. His 'intellectuals' and 'emotionals' are less happily named, the terms being hardly self-explanatory. But a few examples will help to show their recurrent nature. St Paul, the clear thinker, and St Peter, the fervid apostle, for instance, stand at the foundation of the Catholic Church as its twin formative types, intellectual and emotional respectively. This pair of forerunners and founders in the Middle Ages developed and crystallised into monks and priests, or, in more general terms, the regulars and seculars, who, to this day, constitute the bipolar arms of the Roman hierarchy. Further, to illustrate the recurrent generality of these social types, we may trace their adaptation to the successive social formations of later times. In Protestantism the intellectuals and emotionals become respectively divines and pastors; in the revolution they reappear as social philosopher and political orator (recalling the similar manifestations of classical times); modern science knows them as researchers and popularisers; and in the everyday world of to-day they may be recognised in characteristic guise as thinkers and journalists. These are but simple, indeed obvious, examples. It is for the sociologist to discern, describe, and interpret the same four social types in all their manifold varieties generated by each age, even in each generation, and in every effective grouping. Women in their selective social rôle, artists as creators, statesmen and religious leaders at best, are ever found amongst those who, embodying the 'spiritual power' of their times, personalise and re-express it as characteristic 'emotionals,' and thereby bring its influence to bear more directly upon the 'chiefs' and the 'people' of the temporal power. More indirectly, through process of education and counsel, the 'intellectuals' or initiative thinkers of each period operate upon the mind of its representative 'chiefs' and 'people.'

Inquire next how Comte connected his view of history as an interplay of temporal and spiritual powers, with his 'law of the three states.' To affirm the latter in terms of progress from theology as volitional, through metaphysics as abstract, to science as concrete, is to claim for this 'law' an unfolding and development of 'spiritual powers.' A correlative development of 'temporal powers' was necessarily postulated. Thus Comte associated the theological phase of thought with militarism in action, since both are so characteristically volitional; and indeed their frequent association is manifest throughout history. With metaphysics he associated law and politics, and even much of political economy, because legal doctrines, as of 'rights,' political conceptions such as 'state and

individual, and economic conceptions like that of 'value,' are all deeply abstractional, since hypothesising entities instead of investigating realities. With science he naturally associated its applications in industry at its best. Hence his ardent anticipations of a scientific guidance and control of industry towards social well-being in all respects, material, social, and moral. For this direction and ennoblement of industry he looked forward to a new kind of priesthood, at once 'intellectual' and 'emotional,' and -educating, counselling, encouraging a new order of 'chiefs' and 'people' technically competent, yet fully socialised. In this vision of a realisable future, this coming of a 'sociocracy,' scientific critics, like Huxley, saw only 'Catholicism minus Christianity,' while Comte and his disciples claimed it to be 'Christianity plus Science.'

An untoward fate befell the vast structure of pure and applied sociology so elaborately reared by the initiator of the new science. The edifice fell to pieces in the hands of Comte's immediate successors, who carried away what appealed to their limited interests and left the rest to ruin. His acknowledged disciples, the French and English Positivists, concerned themselves with practice of their master's ritual, with exposition of the underlying philosophy, and with advocacy of the applied sociology taken as finished product of an established science. That theoretic or purely scientific part of the sociology, which the positivist groups adopted but failed to develop, found three notable 'continuators' in Herbert Spencer, Émile Durkheim, and Lester Ward, all of whom were hostile or indifferent to many of the practical applications proclaimed and cherished by Comte. Herbert Spencer, while rejecting, and even anathematising, much of the work of the originator (he lacked the historic erudition needed for its appreciation), yet recommended the new social science to English readers in his admirable *Introduction to Sociology*. But in his systematic treatises Spencer ran into a *cul de sac*. He lost sight of Comte's constructive framework in concentrating on two endeavours, one necessary, the other inevitably futile. Certainly it was necessary to incorporate into sociology the products of anthropological research garnered since Comte wrote. And assuredly it was futile, and even mischievous, to try and rebuild sociology on a doctrinal basis of mechanical evolutionism. Lester Ward, in importing the Comtist sociology to the United States, retained its double rôle of a pure and an applied science. But, like Spencer, he lacked historic equipment and ardour of reconstruction, and, like Spencer, he lost sight of Comte's constructive framework in a specialised effort. His endeavour, necessary and fruitful though it was, to restate sociological problems in terms of modern psychology gave a bias to his own work, which has deflected the course of studies and research in America. In France, Durkheim, specifically basing himself on Comte, founded a school of growing influence and output. This school has concentrated on incorporating, within the unity of sociology, all those numerous and growing specialisms (anthropologic, economic, psychological, juristic, &c.) which for the most part have grown up or developed within the widening field of social science since Comte's day. But a criticism is unavoidable. All these specialisms (like sociology itself) are but aspects of the social heritage. How, therefore, can they be united except in and through a working theory of the social heritage? And yet the Durkheim school has, so far, neither replaced nor continued that theory of the social heritage, which is the very core of Comte's sociology, so elaborately built around the concept of history as an interplay of temporal and spiritual powers acting through

the perennial but changing social types of chiefs and people, intellectuals and emotionals.

In reviewing the contemporary state of sociology little else need be said. No expositor or continuator has creatively earned the initiative of Comte into Italy, Spain, Germany, Austria, Switzerland, Belgium, Holland, or Northern Europe; with the result that such sociology as exists in these countries is as yet either discursive or specialised, or of philosophic rather than scientific filiation. The conspicuous exception to this general state is that in Edinburgh, about 1890, Patrick Geddes started an extra-mural school, which, seizing the essential elements of Comte's pure sociology, readjusted them into a framework adapted to current observation of a field-naturalist-like kind in town and country. This renewal and re-systematising of social science (later continued more actively by a group working from Leplay House in London) was largely influenced by another French source, to which brief reference must be made.

The failure, as yet, of Comte's sociology to win an accepted place in the field of science has to be explained. The main obstacle, may be, is not far to seek. Comte himself relied too much on books and reflection: too little on those factual observations which, being open to verification, are the very substance of science. By one of those paradoxes which strew the pages of history, a social science directly observational arose first within the ranks of the counter-revolution, in repercussion, perhaps, from its intensity of emotional drive. The initiator is Frédéric Le Play, a Frenchman and a contemporary of Comte, but to the end of his life apparently unacquainted with the latter's work. Himself of rustic upbringing, Le Play became a metallurgist and mining engineer, and rose to such eminence as to be in demand as a reorganiser of mines in almost every country of Europe from Spain to Russia. He was aroused, in youth, by the revolution of 1830 to close study of industrial conditions. In his subsequent life of constant travel he developed a genuinely scientific method of social observation, and thereby amassed a systematic body of knowledge on working-class families in many countries. Hence his classic *Monographies des Ouvriers Européens*, with its 'family budgets' as estimates of real well-being. His now familiar terms of 'social service' and 'social economy' were moralised beyond conventional business and its economics. His Russian travels brought him in contact with Mongolian shepherd-folk; and thence arose his pioneering studies of the fundamental rural occupations—hunting, pasturage, agriculture, and fishery. He saw these fundamental occupations as determining specific types of family—patriarchal, communitary or individualistic, stable or instable. In each of these again he traced the essential origins of its institutions, and even much of its ideas and ideals. Comte had seen that social life, like organic life, subsists in interaction with its *milieu* or environment; but Le Play gave this conception its full concreteness, in each case tracing how environment occupationally determines the fundamentals of family and social life, yet how social progress is associated with increasing comprehension and mastery of environment. As a true social evolutionist, in his own way, he traced these fundamental occupations and their developments into our contemporary civilisations; and so linked up geography, anthropology, and economics with sociology, not incidentally and discursively, but through systematic observation. His first disciples were, for the most part, a moral *élite* of agricultural and industrial leaders, whose organ, *La Réforme Sociale*, was mainly of practical appeal; but later arose a second group of purely scientific intention, headed

by Tourville and Demolins, with their organ *La Science Sociale*, devoted to developing Le Play's geographico-occupational studies, with fuller interpretations for many characteristic regions and social types. Unhappily *La Science Sociale* came to an end with the Great War.

The sharp separation of revolutionary and counter-revolutionary traditions and parties, which has so long and widely divided France, practically isolated to the one side the influence of Comte (who, starting in the revolutionary tradition, ended by stealing, without acknowledgment, the counter-revolutionary ritual) and that of Le Play to the other; so that their complementary doctrines are only now beginning to be associated, towards a fuller comprehension of society, both in the abstract and concrete. And not less unfortunate than this isolation of Comte and Le Play in their pioneering labours was the fact that each of these two initiators stood more or less aloof from their contemporaries, who were moving, often unconsciously, and all of them without adequate guidance, towards a sociology originating in some specialised approach. Thus have appeared naïf, uncritical, and dispersive sociologies emanating from the generalising students of anthropology, economics, social geography, statistics, religion, social psychology, jurisprudence, politics, and history. The co-ordination of all these and other specialised approaches within a framework, observational, geographic, and economic like Le Play's, and historic and interpretative like Comte's, is manifestly an essential condition of sociological advance. This constructive work awaits the coming generation of sociologists. Their labours, in order to be fully fruitful, must follow and develop the initiatives already taken. Let us, in summary and conclusion, outline somewhat systematically the needed inquiries and activities.

Like the preliminary sciences, physical or biological, sociology must progress inductively from observation towards generalisation, from concrete towards abstract. Concrete and thorough observation (i.e. of place and people in all their aspects), is manifestly essential to sound interpretations, economic and other. Beginning, then, with observation (literally field-naturalist-like), the existing methods of collecting and interpreting social facts have to be harmonised. Hence the need, no less than in the natural sciences, of orderly description and classification, nomenclature and notation. Contributions towards these ends are scattered through the literature of sociology; social observation methods are manifest in everyday life, e.g. accountancy, census and other public records, press, &c. For that systematic study of the social world in all its areas and populations with which sociology has to grapple, all these methods must be utilised and standardised as fully as may be. As the naturalist can never too fully survey his region and observe and correlate its nature and life, so the sociologist must explore his region and its social life, with due records and statistics. Such observation once thoroughly in progress, all freedom of imagination with its audacity of hypothesis, all strength of deduction with its vastness of theory, all glow of social enthusiasm, yet coolness of criticism also, are needed to disclose those processes of social evolution of which we are in search. Without these quickening activities of synthetic aim, our collections of documents, records, and statistics remain at best but half-forgotten libraries, when not mere buried spoil.

The development of the preceding methods of observation is becoming widely known as regional survey; and such surveys are now in progress throughout Britain and many other countries in widening circles, from villages, towns, and their

regional surroundings to cities and states; and from nation to empire and language, to occident, orient, and the world. Thus arises the need and practicability of a social observatory for each city, with departments of study on all the above levels with their various outlooks. Hence also appears the possibility of corresponding practice, i.e. of correlating such a social observatory, on each level, as it were story by story, with the corresponding social laboratory. Examples of all these levels of thought and action are everywhere arising, and are combining towards social survey and social service respectively; so that practical adjustment of these is next needed. Experimental beginnings of such adjustment have long been in progress, as notably at the Edinburgh Outlook Tower and at Leplay House in London, with kindred endeavours elsewhere. Such experimental endeavours are based on surveys actually in progress, however inadequate as yet.

The prosecution of such widening regional surveys, the notation and co-ordination of their observations, involves also a more abstract mapping. For we have (a) to define the place of sociology among the sciences; and (b) to demarcate as clearly as may be the special fields of sociology. We have also (c) to inquire how far these may correspond to the special fields of other sciences, and (d) to investigate, if possible experimentally, the relation of theory to practice in all these fields of sociology and its subspecies. Our scientific faith in an orderly universe implies that our sciences and arts should be, must be, in tune, their detail of daily thought and action in time, their generalisations of social philosophy and polity in harmony.

Investigation of social origins is plainly required. Hence the need of local and comparative ('anthropological' or 'ethnographic') study of the simpler nature-occupations (hunter, shepherd, peasant, &c.) with their masked developments in industry and in science, in family and in institutions, in contemporary customs and habits of mind. Thus may be unified those studies of place, work, and people (organism, function, and environment) upon which geographer, economist, and anthropologist respectively have been wont to specialise. Hence the importance of Le Play and later investigators, with their renewal of the Montesquieu-Buckle-Taine line of interpretation, yet with due psychological treatment also.

Beyond these fields, with which geographer, economist, and anthropologist are usually content, we have still to investigate the origins of higher social developments, as notably of regional art and literature, of education and philosophy, of political, ethical, and religious ideals. We have to recognise both upward progress and degeneration; and we cannot but ask what possibilities there may be of accelerating the one, of redeeming the other. Examples may be sought from antiquity, and especially from Israel, Hellas, Rome, but also from all national histories and from everyday life.

Elemental though are such outlines of the history of civilisation, they remain too environmental, too impersonal: to complement them we need an historic survey, personal and biographic, national and institutional. For this sociological use of narrative history, its facts and dates need orderly arrangement, witness historic charts and atlases. Similarly for historic processes ('philosophies of history') we need a chart of charts. How is this to be devised? History presents not only a phantasmagoria of events, but a succession of phases, with their survivals or continued growths. Primitive, matriarchal, patriarchal, classical, mediæval, renaissance elements are all still discernible, and moreover not merely as archaeological residues,

but as active elements. Fuller analysis of our 'modern order' (say rather 'transition') is necessary, whence increasing discernment within it of a potential or incipient order with its nascent phases. Thus appear dawning possibilities of scientific prevision in sociology as in other sciences; for, as the past is still here in survival, so the future is already here in germ. Fuller economic and ethical interpretations of history appear in the varying interactions of the 'temporal and spiritual powers,' in their permanent elements and their changes. The task of the sociological laboratory is thus not only to advance here politics or economics, or there morals, but to reunite both as etho-politics, the healthy life, both material and psychic, of the social body.

Towards this end we have to correlate the main sciences, mathematical, physical, biological, and social, with the corresponding arts. The mathematical sciences are obviously applied by statisticians and economists, while physical sciences subserve manufactures, transport, and communications, but also find superlative applications in their destructive methods. Our contemporary society is thus especially conditioned by the progress of the physical sciences; yet with the advance of biology, the corresponding vital arts (medicine, hygiene, agriculture) gain in practice and influence, as do education and social progress through the advance of psychology and sociology, and their increasing interaction. The mechanistic view of life, which from Descartes to contemporary physiology has superseded vitalistic theories, is now being subordinated to a more truly vital (because also psychological and social) conception of life and society. The essential biological distinction of nutritive and reproductive functions (i.e. of self-maintaining and species-continuing activities) is congruent with a more moral view of social life and action. Social policy can thus again be viewed as of old; as no mere struggle of political numbers or big battalions, but as etho-policy, and so as guiding the practical applications of the organic and physical sciences. Industries and business have thus to be understood as social service; and since every 'good job' has an aesthetic satisfaction beyond its merely material accomplishment, the fine arts acquire that economic justification which has been too long refused them. In such larger views, of social science and service together, the fundamental schools, especially those of Comte and of Le Play, are being united, and moreover with increasing incorporation of the various observations, interpretations, and endeavours of later workers.

Psychological and moral points of view have thus now clearly emerged. We think of the individual as resultant and spectator of social evolution, and also as an agent in it: and we have a larger yet corresponding view of the social 'spirit of the times,' as the complex expression of the present, and as the fermentation of the future towards new etho-politic ideals. A synthetic—that is, a philosophic—conception of society is thus coming into view. Our studies are now seen to admit of orderly arrangement, and even in harmonious and unified notations, utilisable alike by concrete sociologist and philosopher, by special worker and abstract moralist.

In conclusion we return again, therefore, to the affirmation made at the outset, that everyone starting as a naïf sociologist may increasingly gain competence in theory and practice. Each one cannot but make something of regional survey; he must have some interpretation of current events, and he takes some side in their practical issues. Our brains are therefore clearing-houses of ideas and activities. To know and interpret

our everyday world and its events, we need the collaboration of the best minds in science and in history, in journalism and in criticism, in religion and in philosophy. To aid in progress, not hinder, makes a high claim upon us, not only for sight and insight, but, even more, for insight, both scientific and practical. We need, beyond industry and intelligence, the courage, the statesman-ship which guides events, and along with that the idealism of social evolution, which raises individuals to its level. To promote these conditions is the task of social science and social education; hence the need of schools of sociology (as well as of individual studies), and, moreover, schools which shall be at once centres of social philosophy and training-grounds of social action. To prepare and establish such observatory-laboratories for social science is thus as definite a task for investigator and for educationalists to-day as was lately the foundation of observatories, laboratories, and museums for each of the preliminary sciences. As already indicated, the beginnings of such institutions already exist here and there, and the possibility of further developments now lies more clearly before us in every city, especially in association with its educational advances, its civic progress and development.

LITERATURE.—The best of current writings will be found in the periodicals of which the following are the chief: *The Sociological Review* (beginning in 1904 as *Sociological Papers*, this *Review* is the organ of the (British) Sociological Society, quarterly, Leplay House Press, 65 Belgrave Road, London, S.W. 1.); *Année Sociologique* (organ of the Durkheim School); *The American Journal of Sociology* (University of Chicago); *Revue Internationale de Sociologie* (organ of the Institut International de Sociologie, Paris); *Revue de l'Institut de Sociologie* (Brussels); *Archiv für Sozialwissenschaft und Sozial-Politik*; *Kölnner Vierteljahrschrift für Soziologie*; *Jahrbuch für Soziologie, Geschichte- und Kultur-Philosophie*; *Zeitschrift für Völkerpsychologie und Soziologie*.

No satisfactory text-book of sociology has yet appeared. The works of Comte and Le Play, like those of their precursors, as also of their first continuators, are, in detail, mainly of historic interest. A book for beginners, who wish to start on observational lines, is *Introduction to Regional Survey*, by Sybella Branford and Alexander Farquharson (Leplay House Press). The following works are studies of contemporary civilisation interpreted on the lines followed in the present article. *The Coming Polity* (revised edition, 1919), *Our Social Inheritance* (1919), both by Branford and Geddes; and by V. Branford, *Whitherwards* (1920), *Science and Sanctity* (1923), and *Living Religions* (1924), all Leplay House Press. Leonard Hobhouse's *Metaphysical Theory of the State* (1918), *The Rational Good* (1921), *The Elements of Social Justice* (1921), and *Social Development* (1923), together constitute his *Principles of Sociology*. Graham Wallas's *The Great Society* is a good example of many books moving towards a general sociology from some specialised approach, in this case psychology. In America, text-books by Giddings, Albion Small, E. A. Ross, Ellwood, Cooley, Vincent, and Barnes are in much use.

Socotra, or **SOKOTRA**, an island in the Indian Ocean, 150 miles E. by N. from Cape Guardafui, and 220 from the southern coast of Arabia. Seventy miles long by twenty broad, it has an area of 1382 sq. m. The interior embraces numerous barren plateaus (1500 to 2000 feet), with several well-wooded mountains, rising to 4500 feet; there are fertile valleys between the ranges and belts of rich soil along the coasts. The climate is warm, but healthy. Dragon's blood, myrrh, frankincense, aloes, gum, dates, and ghi are produced. The inhabitants, about 12,000 in all, live on dates and the produce of their sheep, goats, and cows, and occupy themselves with fishing. They belong to two distinct types—one with a comparatively light-coloured skin and straight hair, the other darker with curly hair. But all alike speak the same

peculiar language, which has certain affinities with the South Arabian dialect of Mahra. The people show traces of intermixture with Negro, Arab, and Indian tribes; and in ancient times the inhabitants of Socotia were believed to have been acquainted with Greek civilisation and later to have been Nestorian Christians. From the 16th century at least they owed some sort of allegiance to the sultan of Keshin on the Arabian coast, and adopted the Mohammedan faith. After being occupied by Britain in 1835-39, the island was taken under British protection in 1876 and formally annexed in 1886. The chief town is Tamarida on the north coast.

See ARABIA, also Yule's *Marco Polo* (vol. ii.), and *The Natural History of Sokotra*, by H. O. Forbes (1903).

Socrates, the Athenian philosopher, was the son of Sophroniscus, a sculptor, and Phænaretê, a midwife. As he was at least seventy years old at his death, he cannot have been born later than 469 B.C. He is said, though only by late writers, to have followed his father's profession for a time; and, in the days of the traveller Pausanias (about 160 A.D.), a statue of the Graces, standing at the entrance to the Acropolis, was ascribed to him—with what amount of truth it is impossible to say. He received the usual education of an Athenian youth, and learned also geometry and astronomy. He was acquainted with the philosophy of Anaxagoras (q.v.), probably only through reading his books, and with other speculations about the physical universe. But he came to consider such inquiries fruitless and disappointing. 'To know one's self' was a more pressing task than to know about nature. The most important influence on his mental development was his intercourse with the various Sophists (q.v.) who frequented Athens. Plato (*Meno* 96 D) makes him speak as if he had been a pupil of Prodicus; but he was in no sense a disciple of that sophist. Though in Xenophon's *Memorabilia* (ii. 1) he reproduces Prodicus' moral tale of 'The Choice of Hercules' with approval, he apologises, with obvious irony, for not adorning it with the fine language employed by the sophist, who, we know from Plato's *Protagoras*, was fond of pedantic verbal distinctions. With the other famous sophists of the time (Protagoras, Gorgias, Hippias, &c.), Socrates stood only in the relation of a controversial disputant, though it is clear from the caricature of him by Aristophanes in the *Clouds* (423 B.C.) that ordinary Athenian opinion regarded Socrates as a typical sophist. It may be noted also that Aristophanes, following the vulgar conception of a philosopher, represents his sophist Socrates as engaged in physical researches, though many of the sophists, like Socrates himself, occupied themselves not with nature but with questions of direct practical human interest. Socrates, in bringing down philosophy from heaven to the common life of men (as Cicero puts it), was only carrying out in a conspicuous and earnest way one of the new intellectual tendencies of his age. Socrates, we might say, was the greatest of the sophists, and therefore more than a sophist. Euripides, the poet of the new ideas, is said to have been intimate with Socrates; and the comic poets alleged that Socrates helped him with his tragedies. Whether Socrates really met Parmenides (q.v.), as represented by Plato, we have no means of saying.

Socrates took part in three campaigns: he served at Potidæa between 432 and 429, at Delium in 424, and at Amphipolis in 422. His bravery, his extraordinary physical vigour and indifference to fatigue, or cold, or heat, became known to his comrades during these campaigns. He was a good citizen, obedient on principle to the laws of his city; and he did not hesitate to face the anger of the people

or of tyrants when duty required. The only political office he ever held was when in 406 he was one of the senate of Five Hundred, and then, whilst he was one of the presiding tribe, he alone refused, at great personal risk, to put to the vote the illegal proposal to try in a body (instead of individually) the generals who had deserted the disabled vessels and left the dead unburied at Arginusæ. And, again, during the usurpation of 'The Thirty' he dared to disobey an illegal order. He held aloof from politics, restrained by what he believed to be a divine warning, and considering that he had received a call to the pursuit of philosophy and could serve his country best in that way. Socrates wrote no books. He set up no regular school of philosophy. He simply lived constantly in public, frequenting the gymnasia and the market-place. He did not care to go outside the city walls; 'the trees had nothing to teach him' (as he says in Plato's *Phædrus*). It was from men and about men, men of all sorts and conditions, that he desired to learn, wiser than others only in being conscious of his own ignorance. It was in this sense that he interpreted the Delphic oracle, which had said that no one was wiser than Socrates. Out of his wide circle of acquaintances some came to be attached to him more closely by ties of affection and admiration; yet there was no formal bond of discipleship. We should rather speak of the young friends or the companions than of the disciples of Socrates. From two of these, Xenophon and Plato, we learn all we can know with certainty about his strange personality and his way of thinking. Yet there is this difficulty, that, while Plato often makes Socrates the mouth-piece of ideas that were in all probability not held by him, Xenophon, a soldier and by no means a philosopher, makes Socrates a very much more commonplace person than he must have been. And it must be remembered that Xenophon wrote expressly to justify Socrates to the average Athenian. If we were dependent on Xenophon alone, it would be unintelligible how Socrates could have been the initiator of a great movement in philosophy, and how the Athenians could have been suspicious of so safe and conservative a moralist. Though Plato is apparently not bound by any rigid considerations of historical accuracy in his dialogues, we may yet accept the picture he gives us of the habits and conversation of Socrates as a true portrait—a portrait painted by a great imaginative artist. Aristotle, though of course he could only know about Socrates through Plato and others, sometimes supplies us with a valuable test to discriminate the genuinely Socratic from the purely Platonic elements in the dialogues. Xenophon becomes a useful authority when read in the light of what we know from Plato. Many sayings of Socrates convey profounder meanings to the readers of Plato than they probably did to Xenophon himself. Where Xenophon sees only a prudential maxim, Plato finds the germ of a philosophical principle.

In personal appearance Socrates was odd and even ugly, conspicuously so among a handsome race. He had a flat nose, thick lips, prominent eyes. Alcibiades (in Plato's *Symposium*) compares him to a figure of Silenus. His robust constitution has already been referred to. He always went barefooted, even during a Thracian winter, and wore the same homely clothing all the year round. He was indifferent to luxury and even to ordinary comfort; but he was by no means an ascetic. Habitually abstemious and simple, and possessing perfect control over all his appetites, he could at a banquet drink more than any one else without being overcome. He delighted in the society of youths, especially if they had fair minds in fair bodies.

From a modern point of view, he might seem to pay too little regard to the duties of family life. But we must remember that, though above his age in many ways, he was still of it, an Athenian living almost entirely in a society of men. The well-known gossip about his wife Xanthippe comes to us mostly from late sources. Xenophon only tells us that she had a shrewish temper, which Socrates bore patiently, admonishing his eldest son Lamprocles of the duty of gratitude to his mother (*Mom.* ii. 2). It is easy to believe that a man who had a mission, who was willingly poor, and lived very much in public may have been a trying husband, even to an Athenian wife.

There has been much discussion about the 'divine sign' (*daimonion*) of which Socrates used to speak as a supernatural voice which guided him every now and then, according to Xenophon telling him to act or not to act, according to Plato only restraining him from action, never instigating. Later writers, especially in Christian times, speak of it as a demon, genius, or attendant spirit. For this there is no authority whatever in Plato and Xenophon. On the other hand, we cannot, with some modern writers, identify it with the voice of conscience. Socrates speaks of it as a peculiarity of his own, and it had not to do with the moral quality of actions in general: it was an occasional inward oracle about the future. Socrates, not disbelieving in oracles and divinations (though very likely laying less stress on them than the pious Xenophon would have us suppose), seems to have had certain vivid presentiments which he took for special divine monitions; and it is possible, as has been suggested, that he was subject to occasional hallucinations of hearing, such as may occur even in quite sane and healthy persons. Socrates was eccentric in some ways, and we know that he occasionally became so absorbed in meditation as to become insensible of the outer world. Alcibiades (*Plato, Symp.* 220) relates that Socrates once stood still for twenty-four hours continuously, entranced in thought. It has also been suggested that in some of his allusions to the divine sign there is a trace of irony, and that he may be indirectly satirising the prevalent belief in divination, claiming to have an oracle of his own.

In any case the average Athenian thought there was something blasphemous in the attitude of Socrates to religion. He was charged in 399, under the restored democracy, (1) with neglecting the gods of the state and introducing new divinities (*daimonia*), and (2) with corrupting the morals of the young. These were very much the same charges which had been made against him as the typical sophist by Aristophanes twenty-four years before. They were now made the subject of a legal prosecution by Melétus, Anytus, and Lyco. The Athenian people, though generally tolerant, were liable to outbursts of fanaticism; and it must be remembered that the religion of a Greek state was an integral part of its social and political institutions. Furthermore, among the companions of Socrates had been several of the leading men in the oligarchical faction, such as Critias, Charmides, &c.; and he had also been associated with Alcibiades, who had done so much injury to Athens. A mixture of democratic indignation with that bigoted religious and moral conservatism which is not incompatible with democracy must account for the prosecution and its issues. Plato's *Apology* probably gives the substance of the actual defence made by Socrates—a bold vindication of his whole life, and not such as would be likely to conciliate an Athenian popular jury. Yet the vote of condemnation was carried only by a very small majority (six out of, probably, 500). The punishment had still to be decided on. Socrates himself declared that, if he

were treated as his life deserved, he should be maintained at the public expense in the Prytaneum. But at length, yielding to the pressure of his friends, who were trying to save him, he agreed to pay a fine of thirty minae (i.e. about £120), for which his friends undertook to be his sureties. Provoked by what doubtless seemed to them obstinacy and insolence in the old man, the judges voted the penalty of 'death,' which Melétus had proposed in the indictment: according to Diogenes Laertius (q.v.), this was carried by eighty more votes than the original condemnation. The execution of the sentence was delayed for thirty days because of a sacred embassy to Delos. His friends, who had free access to him, planned his escape from prison; but he refused to break the laws of the state. His last day was spent with his friends, as described in Plato's *Phaedo*; and in the evening he drank the hemlock. 'Such was the end,' Plato makes Phaedo say, 'of our friend, whom I may truly call the wisest and justest and best of all the men whom I have ever known.' Later writers tell how the Athenians repented and punished his accusers; but there is no evidence for this in the writers of the 4th century B.C.

The life and philosophy of Socrates are inseparably connected. Yet he must not be thought of as simply a good man who tried to influence others for good. He sought to base conduct on knowledge. He went about convincing men not so much of sin as of ignorance. What is called the 'irony' of Socrates is his manner of affecting ignorance in the presence of the seeming wise, in order to draw from them an admission of the confusions and contradictions resulting from their opinions. But his conclusion was not mere scepticism or despair of knowledge. He claimed to follow, in the intellectual sphere, his mother's profession, and to help those in labour with new ideas to bring them to the birth: this is his 'maieutic,' i.e. obstetric art. For this reason he always adopted the method of question and answer—the 'dialectic' method in its literal sense. Aristotle (*Met.* xiii. 4) says that Socrates introduced the method of *induction* and the search for *general definitions*. This is a somewhat technical and formal description of the manner and aim of the conversations of Socrates. The Socratic 'induction' consists in going to particular instances. Socrates was laughed at for the homeliness of his illustrations: he was always talking about carpenters and weavers and shoemakers.

Ethics was the only part of philosophy with which Socrates cared to occupy himself, and in ethics his main doctrine may be summed up in the formula 'Virtue is knowledge; vice is ignorance.' (Bentham's saying, 'Vice is miscalculation,' is a somewhat mean-looking version of this.) It follows from this fundamental principle that virtue is one, the excellence of each good quality just consisting in the *knowing* what ought or ought not to be done. It follows also that no one can know (in the truest sense) what is right and yet do what is wrong. In Xenophon we do not find Socrates maintaining any of these opinions in quite so explicit and paradoxical a form. In Plato they are carried out to their logical consequences (see *PLATO*). We find, e.g., that Xenophon makes Socrates say that rulers should be those who *know* the art of ruling. This sounds commonplace enough. But we cannot say that Socrates did not go on to propound Plato's paradox that the perfect state would therefore be one in which the rulers were philosophers.

Xenophon represents Socrates as using the argument from design to prove the existence of the gods. But we cannot say with certainty how far his opinions about the gods differed from those of the popular religion. We may fairly suppose that

they approached more nearly to those of Plato than to those of the average Athenian. On the other hand, from the language of Plato's *Apology*, it seems pretty clear that Socrates did not hold the definite views about the immortality of the soul which are maintained in the *Phædo*, but left the question of a future life quite uncertain.

Socrates founded no special school of philosophy, but gave their starting-point to several distinct schools. Euclides of Megara (not to be confounded with the great mathematician of Alexandria who lived a century later) took up the Socratic dialectic as his main object of study, and, combining Socratic with Eleatic influences, became the founder of the Megaric or 'Eristic' (i.e. disputatious) school. On the other hand, Antisthenes (q.v.) the 'Cynic,' who taught that virtue was the sole end of life, and Aristippus (q.v.) of Cyrene, who taught that pleasure was the end, neglected the intellectual and logical aspects of the Socratic teaching and took a narrowly practical view of the object of philosophy, each maintaining an opposite extreme in his view of goodness. These are often called the 'one-sided' or imperfect Socratics. Plato alone inherited his master's spirit in its fullness.

The part of Zeller's *History of Greek Philosophy* dealing with Socrates is published separately in the English translation (1877), and Lélut, *Du Démon de Socrate* is important. The materials for the life and teaching of Socrates are Xenophon's *Memorabilia* and *Symposium* (the *Apology* ascribed to Xenophon is probably spurious), and Plato, *Apology* (most strictly historical of his writings), *Crito*, the narrative parts of the *Phædo*, *Symposium*. For further reference, see XENOPHON, PLATO; also books in German by Joel (1901), Rook (1903), in French by Piat (1900), in English by R. N. Cross (1914); Burnet, *Socratic Doctrine of the Soul* (1916); Dawson, *Ethics of Socrates* (1925).

Socrates, a church historian, born and brought up at Constantinople about the end of the 4th century A.D. Little is known of his life save that he followed the profession of an advocate. His *Ekklesiastikē Historia* covers the period from 306 to 439, and was most probably written about 440. As history its chief value lies in its transparent honesty, for the writer's grasp of the subject was feeble and his knowledge small. He borrowed from Eusebius, Rufinus, Athanasius, besides eye-witness and oral tradition, mainly from the members of the Novatian party at Constantinople. He had a profound reverence for Origen, and a high regard for Greek culture; and while he himself maintains an easy orthodoxy, he is indifferent to dogmatic definitions and tolerant of erroneous opinion when not noisy. Editions are by Hussey (1853) and W. Bright, with Introduction (1878); there is an English translation in Bohn's Library (1851), another by Professor A. C. Zenos in Schaff's 'Select Library of Nicene and Post-Nicene Fathers' (2d series, vol. ii., New York, 1891).

Soda. In its widest sense the manufacture of soda embraces a chain of operations which includes the making of Sulphuric Acid (q.v.), sulphate of soda, Hydrochloric Acid (q.v.), Bleaching Powder (q.v.), caustic-soda, soda-ash (alkali), and crystals of soda (washing-soda). From some of these processes valuable by-products are also obtained, such as iron, copper, and even silver from the pyrites, after the latter is burned to yield the sulphur required to make the sulphuric acid. This sulphur is now recovered on a very large scale from exhausted black-ash by Chance's process.

Formerly most of the soda of commerce was extracted along with other products from the ashes of certain seashore plants (see BARILLA, and KELP). Natural carbonates of soda (sodium carbonates) are found in different parts of the world, and in some places are worked for use. See SODIUM.

The quantity of soda obtained from all other sources is, however, now quite insignificant in comparison with that produced by the decomposition of common salt (chloride of sodium). This manufacture occupies the chief place among British chemical industries, and is conducted on a gigantic scale. Two processes are employed for obtaining soda, one of these being known as Leblanc's and the other, which is of comparatively recent date, as the Ammonia soda process.

Leblanc's process was first made known to the world by a commission of the French republic in 1794, although dating some years earlier. It has been one of the most valuable discoveries in the entire range of chemical manufactures, and has been practised for a century without any important alteration. The author of this invention reaped no benefit from it himself, but spent the last of his days in an hospital, 'a wreck in fortune, health, and hope.' Owing partly to the war between France and England, and partly also to the existence of a duty of £30 per ton on common salt, which continued for eight years after the close of the war, Leblanc's process was not adopted in Great Britain except on a very limited scale till 1823. After the repeal of the tax in that year Mr James Muspratt erected his celebrated works at Liverpool, adopted the process in its entirety, and succeeded, after overcoming many difficulties, in establishing this great industry in Great Britain. The object of the process is (1) to convert common salt by the action of sulphuric acid into sulphate of soda (sodium sulphate); (2) to reduce this sulphate to the sulphide of sodium by the abstraction of oxygen; and (3) by certain reactions, in which carbonate of lime (calcium carbonate) takes part, to produce either carbonate of soda (sodium carbonate) or caustic-soda. The several stages are as follows.

Production of Salt-cake or Sulphate of Soda (Sodium Sulphate).—The decomposition of common salt is effected by treating it with sulphuric acid, which converts it into sulphate of soda and hydrochloric acid. The reaction takes place in two stages, and is represented by the two equations.

This reaction takes place in the pan A; the mass is scraped out on to the bed of the furnace B when

The gaseous hydrochloric acid produced was for a long period allowed to escape into the air, to the destruction of all vegetation in the neighbourhood, but is now condensed with water. Fig. 1 will serve as a diagram to explain the nature of the salt-cake furnace, called a *blind-roaster* or *muffle-furnace*, for making salt-cake. A is the iron pan in which the charge of common salt and sulphuric acid is first placed, and B is the muffle in which the calcination of the half-finished sulphate is completed, the charge being raked from A into B. The fire (C) heating

Fig. 1.—Vertical Section of Furnace for making Sulphate of Soda.

the muffle is so placed that the fire gases do not get inside, but heat it by external flues. Usually the pan is heated by a separate fire, but in some

instances by the waste heat from the muffle fire. The gaseous hydrochloric acid evolved during the time the reaction between the salt and the sulphuric acid is going on in the pan is sometimes led away to a separate condenser; but if a comparatively pure acid is not required then the gases from both pan and muffle go into the same condenser.

In the case of the *open roaster*, an older kind still used, there is a direct opening from the fire into the bed of the furnace, which is then of an ordinary reverberatory type (see LEAD, fig. 1), with the pan placed at the end as in the blind-roaster; but in this case the pan has always a separate fire. Coke is generally used for fuel in the open roaster, and with it the pan gas is usually separately condensed. Each of these kinds of furnaces has its advantages and disadvantages. The usual charge for open roasters is about 9 cwt of common salt, and for close roasters one half more. With the equivalent quantity of sulphuric acid 100 parts by weight of pure chloride of sodium would theoretically yield 121.45 parts of sulphate of soda, but in practice only about 110 are obtained, owing to the presence of moisture in the common salt. The specific gravity of the sulphuric acid employed varies from 1.700 to 1.720.

Of rotating furnaces for making sulphate of soda, the one patented in 1875 by Jones and Walsh was the first to come into actual operation. It has since been improved by the patentees and others, and is now in use at several large alkali-works. Fig. 2 is a diagram of this furnace. It consists of a rotating iron pan, 16 feet and upwards in diameter, placed in a chamber arched over with firebrick. From the fireplace at one side the fire gases pass over the surface of the charge to the flue at the other side. The salt is admitted by a hopper closed by a balanced cone, and there are lead-pipes for admitting the sulphuric acid at the edge of the pan. Fixed stirrers or ploughs are used for turning over the charge, which, in the largest sized pans, is now sometimes as much as 25 tons of common salt, and this with 20 tons of sulphuric acid gives 27 tons of sulphate of soda every twelve hours. Gas from a producer is sometimes used to heat the furnace, and a self-acting method of emptying the pan was patented by the inventors in 1880. There is a great saving of manual labour by the use of this furnace. Sulphate of soda, although chiefly consumed as an intermediate product in alkali-making, is used by itself in glass-making, in the manufacture of ultramarine, for cold-producing mixtures, and for making various chemicals.

From any of these salt-cake furnaces the hydrochloric acid gas is led away by pipes or flues to condensing towers sometimes 100 feet high, and filled with pieces of coke. The acid vapour enters at the bottom of the tower, and in ascending through the piled coke meets with a descending stream of water from the cistern on the top by which it is absorbed, and flows away as liquid acid through a pipe at the base of the tower to stock-cisterns. Strong hydrochloric acid, which is chiefly used in the manufacture of Bleaching Powder (q.v.), is easily obtained by good condensing appliances either from the rotatory pan furnace or from the pan of a stationary furnace, but the acid from the roaster gas is usually weak. The Alkali Acts of 1863 and 1874 make the condensation of nearly the whole of the gaseous hydrochloric acid produced at soda-works imperative.

Conversion of the Sulphate of Soda into Black-ash.—The sulphate of soda is roasted with coal

and limestone to produce crude carbonate of soda. In this operation the oxygen of the sulphate combines with carbon furnished by the coal to form carbonic oxide. The remaining sodium sulphide interchanges combinations with the calcium carbonate (limestone), forming sodium carbonate, easily soluble in water, and calcium sulphide, which is insoluble. The action of the carbon in reducing the sulphate of soda to the sulphide is shown by the equation

The further change which occurs is thus represented:

The proportions of the materials as now used are the same as those first recommended by Leblanc—viz. sodium sulphate, 100 parts; calcium carbonate (limestone), 100 parts; carbon (charcoal), 55 parts. But as coal is employed in England instead of charcoal, the quantity used is generally 75 to 100 of each of the other two ingredients.

This part of the process is carried out in a revolving furnace, which was first patented in 1853, though many difficulties had to be overcome before it became a success. J. C. Stevenson, of the Jarrow Chemical Works, after much labour succeeded about 1870 in establishing its superiority over the older kinds of balling furnaces. A longitudinal section of this furnace is shown in fig. 3. It is either cylindrical or barrel-shaped, about 18 feet long and 10 feet in diameter, lined with firebrick. The furnace is driven by steam and the necessary gearing, a spur-wheel being placed round and fixed to the cylinder, which turns on friction rollers. At one end it is furnished with a large fireplace, the fire gases from which pass through the 'barrel,' and onwards to heat the boiling-down pans, which are placed at the opposite end and arranged much in the same way as in the stationary furnace. The larger-sized revolving furnaces produce 30 tons of black-ash in twenty-four hours.

Lixivation of the Black-ash.—The crude soda so named requires to be porous, so that water will easily penetrate the broken lumps of it when placed in iron tanks. Formerly a series, say of four of these, was placed in a step-like arrangement in which the lowest contained the fresh black-ash and the highest that which was nearly exhausted of its soda. Fresh water flowed in at the top, and, as it dissolved out the soda, became gradually stronger in descending from tank to tank, till it reached its full strength in the lowest one. A

more recent plan is to have the tanks all on a level and communicating with each other by tubes; but the exhaustion of the black-ash takes place in a similar way. Weak soda liquor is present in the tank with the nearly exhausted ash, and strong liquor in the one containing fresh black-ash, while the other two have liquors of intermediate but unequal strengths. The level of the liquor differs in each, being highest where weakest and lowest where strongest. When communication is opened between these tanks circulation is caused by hydrostatic pressure. The soda liquor from the black-ash is treated differently, according to whether soda-ash or caustic-soda is to be made from it.

Caustic-soda.—As the tank liquor consists of a strong solution of carbonate of soda, it requires to be diluted before it can be causticised with lime. Long iron cylinders contain this diluted liquor, into which

Fig. 3.—Revolving Black-ash Furnace, partly in section: F, fire; R, revolving cylinder; W, friction wheels; H, tanks, &c., for evaporating soda-lye by waste heat of furnace.

lime is placed, and at the same time it is heated and agitated. After being allowed to settle, the clear liquor is drawn off and pumped into liquor-settlers, the lime mud in these being saved and used in the black-ash furnace. Several iron concentrating cisterns are successively used with the aid of heat to bring up by degrees the causticised soda liquor to the required strength. From the last of these cisterns (boat-pans) the liquor, having a specific gravity of 1.550, is run into cast-iron pots, each of a capacity of 10 tons, which are heated by strong fires, and here the concentration of the liquor is completed, and the caustic-soda ladled into sheet-iron drums containing 6 cwt. each. On cooling it solidifies into a white mass of sodium hydroxide or caustic-soda, NaOH , which is now manufactured in large quantities, containing as much as 77 per cent. of sodium monoxide, Na_2O . During the concentration sodium nitrate is used to decompose any sodium sulphide present in the liquor. Caustic-soda is most largely used in soap-making and paper-making, but also in the manufacture of some coal-tar dyes and oxalic acid.

Soda-ash.—When this substance (sodium carbonate) and not caustic soda is to be made, the black-ash liquor is differently treated. In referring to the black-ash furnaces (see fig. 3) it has been stated that their waste heat is used to boil down the black ash liquor. As the concentration of the liquor proceeds granular crystals of soda are deposited and scraped out into drainers. When heated these crystals yield soda-ash; but impure soda remains in the boiling-down vessel. This soda, which is mostly carbonate but also contains caustic-soda and sodium sulphide, is mixed with some sawdust and evaporated to dryness. The black-salt, as this residual substance is called, is then heated in a carbonating oven in which the burning off of the sawdust generates carbonic acid, and this converts the caustic-soda and sodium sulphide present into carbonate, and soda-

ash is the result. The composition of commercial soda-ash is very variable, but it frequently contains about 80 per cent. of the carbonate, the remainder consisting of other compounds of sodium and small quantities of other substances. None of these, however, interfere with its use for the purposes for which it is usually employed. When it is sold the available percentage of soda (sodium oxide or Na_2O) is quoted. For certain purposes soda-ash is refined by dissolving, settling, evaporating, and calcining. It is then called *refined* or *white alkali*, which should be free of caustic-soda and contain no trace of sodium sulphide, sodium sulphate, or of iron.

Crystals of Soda, Washing-soda, $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$.—The soda-ash used for making soda-crystals is previously calcined and dissolved in hot water in iron vessels, the solution being then allowed to cool. From this solution large crystals of almost pure carbonate of soda separate. Ordinary washing-soda consists of these crystals, which are of uniform composition and easily dissolved. They contain ten molecules of water—that is to say, they are composed of 37 per cent. of carbonate of soda and 63 per cent. of water. Crystal soda being quite free from caustic-soda and other compounds acting on the skin, the hands of washerwomen suffer less from it than from other kinds of alkali.

Sodium Bicarbonate, NaHCO_3 .—As will be presently explained, this salt is now prepared on a large scale as a stage in the ammonia-soda process. See SODIUM.

Sulphur Recovery.—The recovery of sulphur from the exhausted black-ash, which forms the waste heaps of the alkali-maker, is now, after many unsuccessful attempts to do so economically, practised on a large scale by Chance's process patented in 1888. This residue, as has been stated, is essentially calcium sulphide, which when brought into contact with carbon dioxide in the presence of water is converted into carbonate of lime, and sulphuretted hydrogen is liberated. The practical difficulty had long been the getting of hydrogen sulphide in a sufficiently concentrated state. Chance's process is as follows: The vat mud (black-ash waste) has the coarser extraneous pieces removed by a sifting process, and is then made into a creamy consistency with water. In this state it is distributed into a series of cylindrical iron vessels for the purpose of having carbon dioxide passed through it. These cylinders have three main pipes passing over them, with branches to each. By one pipe the carbon dioxide is introduced at the bottom of the liquid, and the other two lead the gases away from the top of the cylinder.

The carbon dioxide is produced in a limekiln, and passes, unavoidably mixed with nitrogen, into the cylinders, which successively become richer in sulphur compounds. The result is that for a time little else than nitrogen comes away from the last cylinder. But when the reactions in the cylinders are completed the final vessel of the series gives off gas rich in sulphuretted hydrogen. By means of stopcocks one of the pipes at the top of each cylinder conveys the nearly unmixed nitrogen to an open chimney, and the other takes the rich mixture of nitrogen and sulphuretted hydrogen to a gasholder. When the carbon dioxide from the limekiln passes into the first cylinder containing the black ash waste, carbonate of lime is produced with evolution of sulphuretted hydrogen H_2S . The latter passes on with the excess of nitrogen into the second cylinder, where there is formed sulphhydrate of calcium, CaH_2S_2 , which is a compound of H_2S and CaS . In this way we have the sulphur concentrating from first to last in the series of cylindrical vessels until it is finally expelled as sulphuretted hydrogen gas. In the process the carbon dioxide combines

with the calcium of the sulphhydrate, giving off the two atoms of sulphur as H_2S , so that for one molecule of carbon dioxide two atoms of sulphur are produced. All the time the vessels at the beginning of the series remain unsaturated, the nitrogen, amounting to about 70 per cent. of the gases pumped in, passes away in pipes, and is allowed to escape. It contains little or no sulphur; but by-and-by the gas in the vessels consists of from 30 to 35 per cent. of sulphuretted hydrogen and from 1 to 2 per cent. of carbon dioxide, the remainder being nitrogen. This mixed gas is collected in a gasholder to enable it to be treated as required. The carbonated mud left in the vessels is drained, and used in place of limestone in the black ash furnaces, so that any soda thus dried mud contains is recovered.

A definite mixture of the sulphuretted hydrogen (present in the gas in the gasholder) and air is passed through a layer of anhydrous oxide of iron in a Claus kiln, the oxygen present being only enough to unite with the hydrogen (of the H_2S) to form water, the sulphur being set free. Iron oxide has the power of producing the combination without itself suffering change, the bed of this material becoming (without the use of fuel) sufficiently hot, by the chemical change which goes on, to volatilise the sulphur vapour along with the steam produced. The change is represented by the formula $2H_2S + O_2 = 2H_2O + 2S$. The sulphur is obtained in a very pure state in cakes and flowers of sulphur by this operation.

The *Ammonia-soda process* is gradually superseding that of Leblanc. It is based on the mutual reaction which takes place at ordinary temperatures between common salt and ammonium bicarbonate in strong aqueous solutions. The sodium of the salt combines with the carbonic acid radicle and the chlorine with the ammonia, giving sodium bicarbonate, which is insoluble, and chloride of ammonium, which remains dissolved in the liquid, thus:

The ammonia is recovered from the chloride and one-half of the carbon dioxide from the bicarbonate for future use. Where possible natural brine is used, and this is brought to a specific gravity of nearly 1200, either by the addition of salt if too weak or by adding water if too strong. Ammonia in the free gaseous state is now passed into the brine until the required quantity is present, which is known by the amount of increase in the volume of the liquid. The ammonia enters a mixing tank under a perforated diaphragm, and the liquid is kept in agitation. A great rise of temperature is caused by the condensation of the gaseous ammonia, and this necessitates the running of a stream of water through a coil of piping inside the mixer to keep the heat as low as possible. The brine in running off passes through a filter to retain solid impurities, and then through another worm of piping surrounded by cold water. To form the bicarbonate of soda the ammoniacal brine requires to be saturated with carbonic acid. Air-pumps draw the carbon dioxide from a limekiln and force it (after being properly cooled) at a pressure of nearly two atmospheres in at the bottom of a tower 50 feet high, which is kept nearly full of the liquid. This tower has perforated plates at every three feet of height to make sure that the gaseous bubbles are spread equally through the liquid. Every half-hour some of the pasty mixture in the tower is run off at the bottom. This is full of the small crystals of bicarbonate of soda, and these are separated by running the mass over a wire-gauze filter covered by a cloth, a vacuum being

maintained below. The bicarbonate of soda on the filter is nearly pure, and the liquid which passes through is ammonium chloride. The bicarbonate thus obtained is washed with water and carefully dried in apparatus of which there are various forms. As there is a comparatively limited demand for this kind of soda, it is afterwards heated in close vessels in which half of its carbon dioxide is given off, thereby reducing it to the normal or common carbonate of soda (soda ash). The gas given off is pumped back to the tower and used along with the kiln gas for carbonating fresh material. To expel any ammoniacal salts adhering to the carbonate of soda and render it denser for packing, the heat is continued until fusion takes place. The ammonia is recovered from the liquid filtered from the bicarbonate of soda by heating it with lime. After the ammonia is driven off by heat the remaining liquid is calcium chloride, which is generally run to waste.

Soda Water. See AERATED WATERS.

Söderhamn, a seaport of Sweden, on a bay of the Gulf of Bothnia, 13 miles N. of Gävle, has a large export trade in iron and timber. It has been frequently burned down, the last time in 1863. Pop. 11,500.

Sodium (Na; atom. number 11, atom. wt. 23, sp. grav. 0.973) is one of the metals of the alkalis, its oxide being soda. Its properties closely resemble those of the allied metal potassium. It is of a bluish-white colour, is somewhat more volatile than potassium, and further differs from that metal in having a higher fusing-point—about 97° C.—a greater specific gravity, and in not setting fire to the liberated hydrogen when dropped in water (unless the water is heated). If, however, a piece of unsized paper is placed on the surface of cold water, and the sodium is placed on the paper, the hydrogen takes fire and burns with a deep yellow flame. When heated in the air sodium burns with its characteristic yellow flame, and is converted into soda. When exposed *in vacuo* to a red heat it assumes the form of vapour, and admits of distillation. Like potassium, it must be kept immersed in naphtha, so as to exclude the oxidising action of the air. As a reducing agent it is little inferior to potassium; and as its combining power is lower, and it is obtained much more cheaply, it may usually be advantageously substituted for potassium in reducing operations. Sodium does not occur in the metallic form in nature, but its compounds are very widely distributed. It is found by far the most abundantly in the form of chloride of sodium (or common salt), but it likewise occurs as albite or soda-felspar, cryolite (the double fluoride of sodium and aluminium), borax (the baborate of soda), trona (the sesquicarbonate of soda), and Chile saltpetre (sodium nitrate). Dumas in 1736 discovered that potash and soda (now known to be the oxides of potassium and sodium) were distinct bodies. Sir H. Davy first obtained the metal *Sodium* in 1807. In 1890 it cost 8s. per lb.; in 1908, thanks to Castner's process, it sold at 8d. The symbol Na, an abbreviation of *Natrium*, is derived from *Natron*, one of the old names of native carbonate of soda. The metal is prepared either by the electrolysis of the fused chloride or by electrolysis of the fused hydroxide (Castner's process).

Sodium combines with the elementary gaseous bodies, and two of these combinations, those with oxygen and chlorine, are of extreme importance and value. With oxygen sodium forms two compounds—an oxide, Na_2O , and a peroxide, Na_2O_2 . Anhydrous soda, Na_2O , is procured by heating the metal in a limited supply of air at a temperature below 180° C. and distilling off the metal *in vacuo*.

With full supply of the air and at higher temperature the peroxide Na_2O_2 is formed; Na_2O is of a yellowish-white colour, powerfully attracts moisture, and retains the water so firmly that it cannot be expelled by heat. Caustic soda, NaHO , closely resembles, both in its properties and in the mode of procuring it, the corresponding potash compound. It is, however, not so fusible as the latter, and is gradually converted, by exposure to the air, into carbonate of soda, which is also an infusible salt in its anhydrous state. Solution of sodium hydroxide (or soda lye) is largely employed in the arts. It is prepared by boiling a tolerably strong solution of carbonate of soda in milk of lime until a portion of the filtrate ceases to effervesce on the addition of an acid. The solid hydroxide has a specific gravity of 2.13, and the quantity of anhydrous soda in any solution may be closely approximated to by determining the specific gravity of the fluid and referring to a table indicating the strength corresponding to the specific gravity.

Many of the combinations of the oxide of sodium (soda) with acids—constituting sodium salts—are of great importance. There are two carbonates, acid and normal.

Sodium Carbonate.— $\text{Na}_2\text{CO}_3 + 10\text{H}_2\text{O}$, the *Soda* of commerce, is a colourless, inodorous salt, with a nauseous alkaline taste. It crystallises in large transparent rhomboidal prisms, which contain nearly 63 per cent. of water, but it readily parts with all this water on the application of heat. The crystals also lose the greater part of their water on mere exposure to the air, when they effloresce, and fall to powder. Water at 60° (15° C.) dissolves half its weight of the crystals, and boiling water considerably more, the solution acting like an alkali on vegetable colours. This salt, the *natron* of commerce, occurs native in the natron-lakes of Hungary, Armenia, &c., in association with sulphate of sodium and chloride of sodium. In other regions it appears in an efflorescent form on the surface of the earth. For its manufacture, see SODA.

Sodium Bicarbonate, NaHCO_3 , may be formed by passing a current of carbon dioxide through a strong solution of sodium carbonate, till saturation takes place, and allowing the mixture to crystallise; or it may be produced on a large scale by exposing crystals of sodium carbonate to a prolonged current of carbon dioxide. Most of the bicarbonate in commerce is now, however, prepared by the ammonia-soda process (see SODA). This salt is used largely in medicine. See AERATED WATERS.

Sulphuric acid forms with soda a normal and an acid sulphate. The normal *Sodium Sulphate*, $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$, has been already described under its synonym of *Glauber's Salt* (see GLAUBER). The acid salt, or *sodium bisulphate*, NaHSO_4 , is of no special interest.

Sodium Thiosulphate, $\text{Na}_2\text{S}_2\text{O}_5 + 5\text{H}_2\text{O}$, occurs in large colourless, striated, rhombic prisms, of a cooling and sweet taste. When strongly heated in the air it burns with a blue flame. It dissolves readily in water, the solution depositing sulphur when exposed to air. It may be obtained by digesting a solution of sodium sulphite with powdered sulphur. The sulphur is gradually dissolved, and forms a colourless solution, which, on evaporation, yields crystals of sodium thiosulphate. This salt is largely employed in photography, and is occasionally prescribed medicinally. Sulphurous acid forms two salts with soda—viz. a sulphite and a bisulphite. The *Sulphite*, $\text{Na}_2\text{SO}_3 + 7\text{H}_2\text{O}$, is obtained by passing sulphurous acid over carbonate of soda, dissolving the resulting mass in water, and crystallising, when the salt is

obtained in efflorescent oblique prisms, which are soluble in 4 parts of cold water, the solution having a slightly alkaline reaction and a sulphurous taste. This compound was at one time commercially known as *Antichlor*, and was largely used in paper-manufactories for the purpose of removing the last trace of chlorine from the bleached rag-pulp. The term is now applied only to the thio-sulphate, which is both cheaper and more efficacious. The *Bisulphite* is of use in the arts. *Nitrate of Soda*, NaNO_3 , known also as *Cubic Nitre* or *Chile Saltpetre*, occurs as a natural product on the surface of the soil of certain South American districts. In most of its properties, excepting its crystalline form, and further in its being deliquescent, it resembles nitrate of potash. It is used as a Manure (q.v.). The *Phosphates of Soda* are comparatively numerous. *Hypo-chlorite of Soda*, NaClO , is at present known only in solution, in which it occurs as a yellowish-green fluid, evolving a smell of chlorine; it has strong bleaching power, and when boiled becomes decolorised, and evolves chlorine freely. It is formed by passing a stream of chlorine gas through a solution of carbonate of soda, the resulting solution containing the hypochlorite, together with undecomposed carbonate of soda and chloride of sodium. This solution is useful as a bleaching agent, as an oxidising agent in analytical chemistry, and as a disinfectant agent. There are two *Borates of Soda*, of which the only important one, the *Biborate*, is already described under its ordinary name of *Borax* (q.v.). Various *Silicates of Soda* have been formed (see SILICON, GLASS, SLAGS).

The *Haloid Salts* of sodium resemble, in their general characters, the corresponding salts of potash. Of these by far the most important is *Chloride of Sodium* or *Common Salt*, formerly known as *Muriate of Soda*, NaCl . It occurs naturally in far greater quantity than any other soluble salt, and is fully described at SALT. The other haloid salts—the iodide, bromide, and fluoride of sodium—require no notice.

Sodium has been found to enter into various groups of organic bodies—the sodium-alcohols, for example. When sodium or potassium is gradually added to anhydrous alcohol the temperature rapidly rises, the metal is dissolved, hydrogen is evolved, and a fusible deliquescent compound is formed, which has received the name of *Sodium-alcohol* (or potassium-alcohol), or of *ethylate of soda* (or potash), its composition being such that it may be regarded as alcohol in which one atom of hydrogen is replaced by one of the metal.

The *tests* for the salts of sodium are not very satisfactory, because the metal forms scarcely any insoluble compounds. A salt of sodium is usually concluded to be present when, the absence of all other bases having been proved, a saline residue remains, which, with bichloride of platinum, yields yellow striated prisms by spontaneous evaporation. Before the blowpipe the salts of sodium are known by the intense yellow which they communicate to the outer flame, and if a weak alcoholic solution of one of the salts is burned a similar yellow tint is communicated to the flame. Spectrum analysis is too delicate to be of much practical use.

The *medicinal uses* of the sodium compounds may be considered alphabetically. *Acetate of Soda* is a mild diuretic, similar in operation to acetate of potash, for which it may be substituted. *Arsenate of Soda* is serviceable in periodic affections, chronic skin diseases, and the cases in which arsenic is generally employed in medicine. Paper impregnated with a solution of arseniate of soda sweetened with sugar is sold as a poison for flies. *Biborate of Soda*, or *Borax*, is employed principally as a topical astringent, and is used with advantage

in aphthous eruptions of the mouth and throat. A solution of *Chlorinated Soda* is preferable to hypochlorite of lime in destroying noxious effluvia, as the salt which is left does not deliquesce. *Phosphate of Soda*, known also as Tasteless Purging Salt, is a mild saline purgative, with a far less unpleasant taste than sulphate of magnesia. *Sulphate of Soda* and *Tartrate of Soda and Potash* have been already described under their ordinary names of Glauber's Salt (see GLAUBER) and Rochelle Salt (q.v.).

Sodom, APPLE OF, the name given to the fruit of a species of *Solanum* (q.v.). But it is possible that the true Apple of Sodom, or Mad Apple, of the shores of the Dead Sea, mentioned by Strabo, Tacitus, and Josephus, and described as beautiful to the eye, but filling the mouth with bitter ashes if tasted, is a kind of gall growing on dwarf oaks, and produced by a species of gall-insect.

Sodom and Gomorrah, two ancient cities, almost invariably spoken of in conjunction in the Bible, and forming with Admah, Zeboiim, and other towns the 'cities of the plain,' which on account of the enormous wickedness of their inhabitants (the nature of which is indicated in the term Sodom), are said to have been overthrown, prior to the formation of the Dead Sea (q.v.). The name Sodom is found on the southern shore, at the salt ridge of Usdum, and not far from the supposed site of Zoar. The story (Gen. xviii. sq.) is that of some widespread cataclysm, the punishment of heinous sin and the reward of the pious, hospitable Abraham; and it ends with the birth of Moab and Ammon; see ABRAHAM. On the many questions which the narrative raises, see especially Skinner's *Genesis*, pp. 311 sq., 314.

Sodoma, or SODONA, IL, was the usual appellation of Giovanni Antonio Bazzi (1477-1549), religious and historical painter, born at Vercelli, who painted in Rome, but chiefly at Siena, where he died. His best-known pictures are the famous frescoes in the Villa Farnesina at Rome. See *Life* by the Countess Priuli-Bon (1901), and books by Cust (1906) and Gielly (1911).

Sodomy, an unnatural crime, is punishable with penal servitude for life, or any term not less than ten years, and the attempt to commit it is punishable with penal servitude from three to ten years. In Scotland it was till 1887 nominally a capital offence, though not punished except by penal servitude and imprisonment.

Sodor and Man. See HEBRIDES, and MAN.

Soest, in Westphalia, 37 miles SE. of Munster by rail, once a fortified Hanse town and a free imperial city of considerable importance. The municipal law of Soest served as the model for Lübeck, Hamburg, &c. In 1180 the Archbishop of Cologne seized the sovereignty; but in 1441 the people rose and sought the protection of the Duke of Cleves, and this led to a siege and heroic defence. The Gothic Cathedral (Catholic), built in 1314, was restored in 1846. Pop. 20,000.

Sofala, the name given to that portion of the south east coast of Africa which extends from the Zambezi as far south as Delagoa Bay. The inland region at the back of the coast district, partly corresponding to Matabeleland, was anciently known as the Empire of Monomotapa (though the word is rather the name of the prince than of the state). Sofala was described by the old geographers as a very rich, gold-producing country, and was judged by some to be the Ophir of Solomon, an idea afterwards long discredited, but revived since Mauch discovered the disused mine-workings around Zimbabwe (q.v.), and in-

terest was aroused in them through the British South Africa Company penetrating into that region. Sofala belongs to the Portuguese, who established themselves here in 1505. Their headquarters, the town of Sofala, once a large commercial town, is now a wretched place of 1200 inhabitants.

Sofia, the capital of Bulgaria, stands on a plateau some 1800 feet above sea-level, surrounded by mountains, including Mount Vito-ka. The city, on the railway connecting Constantinople with Belgrade and Vienna, has undergone thorough reconstruction since 1891, most of the crooked dirty streets, with their tumble-down houses and ruinous mosques, of the old Turkish city being demolished to make way for broad tree-planted boulevards, large public gardens, new French-looking houses, shops and hotels, and large public buildings (national library, banks, post-office, &c.). The national opera-house and national theatre, the government buildings, and the royal palace are worth special mention. There are many Orthodox churches and a large Mohammedan mosque. The Cathedral of Alexander Nevsky, with its golden dome, was practically completed at the time of the Balkan Wars, but was only consecrated in 1924. The next year it suffered very greatly from the explosion of a bomb placed in the roof (as the outcome of a Communist plot), when 140 persons were killed during an official memorial service. Sofia is the seat of the Exarchate of the Bulgarian Church (since 1913), and of the national university (1888). There is a considerable trade in hides, spirits, maize, and wheat, and since the Great War Sofia has become an extremely busy commercial centre. For centuries the place has been renowned for its hot mineral springs (117° F.). Pop. (1870) 19,000; (1893) 46,593; (1910) 85,000; (1920) 154,025. Over two-thirds of the population (which is rapidly increasing) are Bulgarians, the remainder being (Spanish) Jews, Turks, &c. Sofia is the *Serdica* of the Romans, and was the seat of a famous church council in 343. Attila plundered it, and Justinian I. rebuilt it; it was in the possession of the Bulgarians from the beginning of the 9th century until its capture by the Turks in 1386. Both Hunyady and the Albanian chief Mustapha Pasha (in 1829) utterly devastated the place, and it was occupied by the Russians under General Gurko in January 1878. The same year it was chosen as the capital of the new principality of Bulgaria.

Sofia, a student of Mohammedan theology and sacred law.

Soft-grass (*Holcus*), a genus of Grasses (q.v.).

Sogdiana, anciently a province of the empire of Persia in the time of the Achaemenians, corresponded to the modern districts of Samarkand and Bokhara and the valley of Zerafshan. Under the Greeks, after its conquest by Alexander the Great, it was united with Bactria. The Arab geographers eulogise its fertility and beauty.

Sohar, a seaport of Oman in Arabia, stands on the Gulf of Oman, 130 miles NW. of Muscat, and is a well-built place with town-walls and a castle, some weaving and working of metals, a good harbour, and an active trade. It was a famous trading-town in the end of the 10th century, but has sunk to a place of 5000 inhabitants. The Portuguese occupied it from 1508 to 1650.

Sohrab and Rustam. See FIRDUSI.

Soignies, a town of the Belgian province of Hainault, 22 miles by rail S. by W. of Brussels. The church of St Vincent dates from the 12th century, though it was first founded in 650. Pop. 11,000. Near here the French defeated the Netherlanders on 10th July 1794.

Soils. 'Soil' is the term applied to the loose earthy layer which normally covers the solid rocks of the earth's crust. Soils are formed from rocks by the process of weathering (see DENUDATION), which process is, in part, one of mechanical disintegration. Thus moving ice, running and freezing water, and blown sand are well known to have a pulverising effect on rocks. Natural soils, however, differ chemically as well as physically from the rocks which give them origin. The main chemical processes of weathering are oxidation, due to contact of the rock material with the atmosphere or with water containing oxygen, and leaching by natural waters which contain small amounts of carbonic and other acids. Further, natural soils always contain, mixed with their mineral constituents, a greater or less proportion of vegetable or animal remains in process of decay.

Of the minerals which compose the rocks of the earth's crust, *silica*, in the form of quartz, flint, &c., is the most abundant. It suffers no chemical change in the process of weathering, and hence quartz sand is the commonest constituent of soils. Chemically pure silica has no value in plant nutrition, but natural silicas frequently contain impurities in sensible quantities, some of which are important as plant foods. Quartz sand, owing to its mode of formation by purely physical processes, generally occurs in the form of relatively large grains. Sandy soils have little coherence and are easily tilled ('light' in the farmer's sense), but they have little capacity for retaining moisture or soluble manures. They are warm and early, but 'hungry,' and crops growing on them are liable to suffer from drought. Next to silica, the commonest rock-forming minerals are the group of double silicates of alumina with an alkali or alkaline earth. Some of these, such as the micas, are very resistant to chemical change, and occur in soils largely undecomposed. Others, notably the feldspars, yield readily to natural chemical agents, the potash, soda, lime, magnesia, &c., being leached out by carbonated water. The end product of this process is a hydrated silicate of alumina, which constitutes *clay*. In humid climates the soluble salts formed in this process are largely washed out of the soil by percolating rain and are carried in the drainage waters to the sea. In arid and semi-arid regions, on the contrary, they accumulate in the soil, and are often to be found as solid incrustations on the surface, left by the evaporating soil waters. Where such excessive quantities of soluble salts are present, the soil may be practically sterile, or may support only a few peculiar salt-resistant species of plants. Such are known as *alkali lands*. Many such soils can be rendered fertile by appropriate treatment. Chemically pure clay, like quartz sand, contains no element valuable as plant food. The natural clay in soils is, however, always impure, and in particular usually contains quantities of *zeolite* material, which is an intermediate stage in the formation of clay from the rock minerals. Zeolites are an important source of plant food. Clay generally occurs in the form of minute particles, and in soils a proportion is always found in the colloidal condition. Clay soils are plastic, tenacious, and difficult to till (hence 'heavy'), are retentive of water and manurial salts, and shrink and crack on drying.

A third substance which occurs in soils in considerable but varying amounts is *humus*, a mixture of complex organic compounds resulting from the decay of vegetable and animal remains. The humus of soils is continually in process of decomposition, which is most rapid in moist, aerated, cultivated ground, and slowest where, for example by stagnant water, air is excluded. Humus is a dark-coloured spongy material, with great capacity for

absorbing and retaining water, but without the tenacity of clay. It necessarily contains all the elements of plant food, but these are yielded up in available form only as the material decays. Soils containing large quantities of neutral humus in process of decomposition—e.g. the black soils of the fens of England—are very fertile; on the other hand, the stable and acid form which constitutes ordinary peat is of little agricultural value. The physical qualities of humus are of greater importance than the chemical. Its admixture with sandy soils renders them more retentive of water, while to clay it gives a friable and crumbly structure, which facilitates cultivation and improves tilth. Since cultivation speeds up greatly the natural rate of decay, measures for the maintenance of the humus content of the soil are of prime importance in any lasting system of arable farming. Such measures are the application of farm-yard manure and the ploughing under of portions of plants, or more rarely of entire crops grown for the purpose. The value of such materials has of course been recognised from the earliest times, and is only in part explained by the quantities which they contain of the elements valuable as plant food.

Chemically, the soil is to be considered as the source of the majority of those elements which are essential to the life of plants. Some of these elements—*calcium*, *magnesium*, *sulphur*, and *iron*—are contained in practically all natural soils in quantities that are abundantly sufficient for plant requirements. On the other hand, supplies of any or all of the three elements, *nitrogen*, *potassium*, and *phosphorus*, in available form, may be insufficient, in so far as to set a definite limit to the amount of plant growth that the soil is capable of supporting. Hence salts containing nitrogen, such as nitrates and ammonium salts, and also potassium salts and phosphates, are largely used as Manure (q.v.). The soil is not, however, to be regarded simply as a storehouse of these materials, but rather as a factory with a continuous output of plant food. The general truth of this view has been conclusively demonstrated at Rothamsted Experiment Station, where on certain plots wheat has been grown continuously since 1852, no manure of any kind having been applied in the interval. The yield has long ceased to show any secular change, and reaches an average, over series of years, of about 12 bushels per acre; this figure being therefore a measure of the rate of production, in the soil, of available plant food. In so far as concerns the substances of mineral origin, such as potash and phosphates, the processes by which plant food is rendered available are only a continuation of the general process of weathering—i.e. they are physico-chemical in character. On the other hand, the preparation of nitrogen for the plant is carried on mainly by biological agents, bacteria and other micro-organisms which occur in vast numbers in all fertile soils. These organisms are of two essentially different types, the one being concerned in the decomposition of organic compounds of nitrogen and in the oxidation of the resulting ammonia to the form of nitrates, in which form the nitrogen is available to all higher plants; while the other type are concerned in the fixation of free atmospheric nitrogen which is not directly available. Some of the latter, such as *Azotobacter*, are free living, while the *Bacillus radicicola* lives in a condition of symbiosis or partnership with plants of the leguminous order. It is clear that the soil must be considered as a medium for the life of these organisms, and from this point of view aeration, warmth, and the presence of a base are essential. The latter requirement furnishes the chief explanation of the value of lime (calcium carbonate) in soils, the addition of lime being a

most important measure in all cases where it is naturally lacking. The removal of stagnant soil water by drainage is also of prime importance to the welfare of the soil organisms.

For a fuller discussion of Soil Science, see Hall, *The Soil*; Lyon and Buckman, *Soils*; Russell, *Soil Conditions and Plant Growth*. See also AGRICULTURE, MANURE, NITRIFICATION, NITROGEN FIXATION, &c.

Soissons, a town and former fortress of France, dept. Aisne, stands on the river Aisne, 65 miles N.E. of Paris by rail. Soissons is the key of Paris for an army invading France from the Netherlands, and is the meeting point of several military roads. The principal building is the fine 13th century Gothic cathedral, the library of which contains many rare MSS. The beautiful south transept (dating from the end of the 12th century) has two triforium galleries beneath the clerestory. During the Great War the north transept and nave suffered severely by bombardment, as did also the remains both of the great castellated abbey of St Jean des Vignes (1076), where Thomas à Becket found refuge when in exile, and of the abbey church of St Léger (1139). The church of St Peter (Romanesque) dates from the 12th century. Quite near to Soissons is an institution for deaf and dumb, which occupies the site of the famous abbey of St Médard (560), where Clothaire and Siegbert were buried. The town hall contains a library and museum of antiquities. Soissons has a busy trade in corn, acting as source of supply for Paris, and has some manufactures. Pop. (1921) 14,391. Soissons is one of the oldest towns in France, and was celebrated even in the time of the Romans, when it bore the name first of *Noviodunum*, and afterwards of *Augusta Suessionum*; hence its modern name of Soissons. It was the second capital of Gallia Belgica, and subsequently the most important town of the Romans in northern Gaul. Near to it Clovis overthrew Syagrius, the Roman commander, in 486. The same prince made Soissons the seat of the Frankish monarchy of Neustria. Here Pepin was crowned king, and Louis the Pious imprisoned. It was the gathering-place of more than one important council, and has been repeatedly captured and sacked in war—e.g. six times during the Hundred Years' War, by the Armagnac party in 1414, by Charles V. (1544), the Huguenots (1565), three times in 1814, and by the Germans in 1870. Soissons was occupied by the Germans in 1914, but after the battle of the Marne (September 1914) they were forced to retire to the heights (including the famous 'Chemin des Dames') which covered the town from the N.E., when the battles of the Aisne began. From this position they were dislodged by Nivelle's offensive (April 1917), but they occupied the town again from May to August 1918.

Soke, a form of the word *Soc*, meant in old English times both the privilege of holding a court and the district held by tenure of Socage.

Sokoto, a Central African state, forming the north-west portion of the British protectorate of Nigeria since 1900, when the Niger Company surrendered its rights to the Crown. The people are Hausa (q.v.), ruled by Fulahs (q.v.). The area of the province, considerably smaller than that of the empire ruled over by the Fulahs in the 19th century, is estimated at about 35,000 sq. m. The country is generally level, but rises to 10,000 feet in the province of Adamawa; and it is well watered by the Benue and its tributaries. There are large deposits of good iron; fruit is grown, and there are possibilities for cotton. The inhabitants number about 500,000. In 1885 the sultan of Sokoto, known as the Sarkin Musulmi (Commander of the Faithful), put his kingdom under the protectorate

of Britain, and granted to the Royal Niger Company a monopoly of the trade. The town of Sokoto, or Sakatu, in the north-west corner, has shared with Wum, 18 miles east, the rank of capital. Its surrender in 1903 terminated the Fulah tyranny. Near it Clapperton died (1827). See books named at NIGERIA.—There is also a town called Sokoto in Abyssinia, 100 miles east of Gondar.

Solanaceæ, a family of dicotyledons, mainly herbaceous plants and shrubs, but including a few tropical trees. The leaves are mostly alternate, undivided or lobed, without stipules. The flowers are regular, or nearly so; the calyx and corolla generally five-cleft; the stamens generally five. The fruit is either a capsule or a berry, usually two-celled. The plants of this family are mostly natives of tropical countries, a small number extending into the temperate climates; in the coldest regions they are entirely wanting. They are mostly distinguished by an offensive smell and by containing a narcotic, poisonous substance, usually associated with a pungent principle, and some of them are amongst the most active poisons. Sometimes the narcotic substance predominates, as in Mandrake (q.v.) and Henbane (q.v.); sometimes the pungent substance predominates, or is alone present, as in Cayenne Pepper (Capsicum); sometimes both are present in more or less equal proportion, as in Tobacco, Thorn-apple, and Belladonna. The fruit is generally poisonous; but that of a considerable number of species, in which acids and mucilage predominate, is eatable—e.g. the berries of the Winter Cherry and other species of *Physalis*, of the Egg-plant (q.v.) and some other species of *Solanum*, and of the Tomato (q.v.). The tubers, which occur in a few species, contain much starch, and serve for food, the Potato being the chief example. The seeds of all contain a fixed oil, which in the south of Germany is expressed from the seeds of the Belladonna itself.

Solan Goose. See GANNET.

Solanum, a genus of Solanaceæ, containing a great number of species, distributed all over the world, but particularly abundant in South America and the West Indies. Some are herbaceous, others shrubs; some unarmed, and some spiny; many covered with a down of starlike hairs. The flowers are in false umbels, or almost in panicles; seldom in racemes or solitary. The anthers open by two holes at the top. The berries are two-celled, and contain many smooth seeds. The species of this genus almost always contain in all their parts a poisonous alkaloid, *Solanine*, sometimes so much that the leaves or berries cannot be eaten without danger, whilst in a few species the quantity present is so small that these parts are eaten freely, being agreeable and harmless. By far the most important of all the species is the Potato (q.v.), in which, however, solanine is found in considerable quantity, so that not only the herbage, but the juice of the raw tubers, is unwholesome. Of the species with eatable fruit the principal is the Egg-plant (q.v.). The only British species are the Bitter-sweet (q.v.) and Common Night-shade (q.v.), both of which possess poisonous and medicinal qualities. The berries, leaves, bark, and roots of various species are employed for different medicinal uses in warm countries. The berries of *S. saponaceum* are used as a substitute for soap. The fruit of *S. sodomense*, Apple of Sodom, a native of North Africa, contains a greenish pulp when ripe, which if eaten causes headache, madness, and death. *S. quitense* yields a wholesome fruit resembling an orange in appearance and somewhat also in flavour. The fruit of *S. muricatum* is eaten in Peru and has the flavour of a melon. The Kangaroo-apple of Australia is the fruit of *S. nemorense*, which is wholesome

when ripe, but poisonous when unripe. The berries of *S. incanum* are employed in Egypt to curdle milk.

Solar Microscope is an apparatus for projecting upon a screen by means of sunlight an enlarged view of any object. It is essentially the same as the combination of lenses used in the Magic Lantern (q.v.) taken in conjunction with a heliostat. A heliostat is a plane reflecting mirror which by means of clockwork follows the sun's apparent motion so as always to throw its rays in the direction in which they are first adjusted. By this instrument the rays are thrown horizontally into the solar microscope, and are concentrated first by a large lens and then by a small lens upon the small object that is to be projected. As they diverge the rays are collected by an adjustable system of lenses and focused sharply on a screen. Uncertainty of sunlight very much circumscribes the usefulness of the apparatus.

Solar Myth, a myth allegorising the course

of the sun; by some mythologists constantly invoked to explain the problems of Mythology (q.v.).

Solar System, the name given to the Sun with the planets and comets which revolve round it. The most important members are the large planets given in the following table. All rotate about axes, and consequently the equatorial diameters are greater than the polar diameters. The difference is not great for the Sun and the four nearer planets, but is considerable for the larger ones, amounting to as much as one-ninth part for Saturn. The most important feature in the Solar System is that the planets move in nearly the same plane (the Ecliptic) and in the same sense. To this circumstance and the relatively great mass of the Sun is due the important fact that the mutual attractions of the planets make only periodic and not permanent changes in the system. See PLANETS, COMETS, SUN, MOON, SATELLITES, METEORS, GRAVITATION.

Name.	Diameter in miles	Reciprocal of Mass (Sun=1)	Density. (Earth=1.)	Gravity at Surface (Earth=1)	Period of Rotation.	Distance from Sun (millions of miles)	Period of Revolution (in days)	Velocity in Orbit (miles per sec.)

Solder, a fusible alloy used for joining metals. For some of these there are two classes of solders, called hard and soft. Under the head BRAZING the composition of hard solders for brass and copper is given. Common brass makes a solder for iron. 'Silver solders,' which melt at a lower temperature than ordinary hard solders, are used for brass, copper, and sometimes even for iron. One kind is composed of equal parts of silver and brass; another variety consists of these two metals and zinc in equal proportions. These solders are a little costly, but when they can be used they give much satisfaction. The solder used by silversmiths is usually made of two of silver and one of brass. Goldsmith's solder varies with the fineness of gold to be joined, the coarsest kind being formed of three of gold, two of silver, and nearly two of copper; but the proportion of gold is much higher for fine work. Soft solders for brass consist of two of tin and one of antimony, and of lead and tin in equal or nearly equal proportions. The latter is also used for lead, but plumbers use besides a mixture of one of tin to two of lead. For pewter a little bismuth is added to these two metals. A solder of two of tin and one of lead does for zinc. Suitable solders for the above metals can be purchased already prepared. The fluxes usually employed are borax or sal ammoniac for hard solders, and resin, muriatic acid, or Baker's mixture for soft solders.

Soldier. See ARMY, ENLISTMENT, MARTIAL LAW, TACTICS, WAR.—**SOLDIER BEETLE** is a name given to coleopterous insects of the genus Telephorus, from their red colour and combativeness.—**SOLDIER BIRD** is an Australian Honey-Eater (*Meliphaga sanguinolenta*), named from the male's crimson plumage. For Soldier-crab, see HERMIT-CRAB.

Soldo. See SOLIDUS.

Sole (*Solea*), a genus of flat-fishes (Pleuronectidæ), distinguished by the following characters: mouth rather small and not terminal, its lips curved on

each side towards the ventral edge of the head; teeth present only on the lower or left side, where also the jaws are larger and stronger than on the right; eyes small and not prominent, on the right side, the dorsal anterior to the ventral; scales small, ctenoid—i.e. fringed with spines posteriorly; lateral line straight on the body, but with an anterior dorsal curve on the head; tactile filaments on the lower side of the snout. Paired fins may be rudimentary or absent. The dorsal fin commences on the snout, and is not continuous with the caudal. The shape of the fish is oval, the outline of the snout being semicircular, and projecting somewhat beyond the mouth. The common sole (*S. vulgaris*) is a fish

Common Sole (*Solea vulgaris*).

of high value in the market. It is captured in the North Sea from Yorkshire southwards, in the English Channel and Irish Channel, and off the south coast of Ireland. Off the Scottish coasts it occurs only in small numbers. Beyond Britain it ranges along the west coast of Europe and throughout the Mediterranean. The largest supply of soles comes from the North Sea, nearly four times as many being landed on the east coast as on the south coast of England, while the west coast produces about the same quantity as the south, the produce of the Irish grounds being included in the former. The Common Sole is the largest of the British species; it is distinguished by the

following characters: pectoral fins well developed on both sides, nostrils on the two sides similar, filaments of the lower side of the snout crowded without arrangement. The colour of the upper side consists of longitudinal series of black blotches on a yellowish-brown ground. The sole has been known to reach a length of 26 inches and a weight of 9 lb., but its usual size varies between 10 and 20 inches and its weight from 1 to 2 lb. It spawns in March and April chiefly, but some individuals may shed their ova in May. It breeds on the grounds where it lives, and its ova are small and buoyant. The young, at a very early stage after they have metamorphosed, are occasionally found in tidal pools, but after about 1 inch in length they are probably to be found in deep water. The adults are frequently taken in estuaries in summer time, and have been said to thrive in fresh water, though that is doubtful: they certainly do not breed in fresh water.

The Sand Sole, sometimes called Lemon Sole (*S. lascaris*), is distinguished from the common sole by having specks instead of blotches on its coloured side, and a dilated nostril on the lower side. Its habits are similar to those of the common sole, and it is sent to market with it without distinction, but it is very scarce. The Thickback (*S. variegata*) is found only on the south coasts of England and Ireland, extending thence to the Mediterranean. It is smaller than the two previous species, seldom exceeding 9 inches in length. It is distinguished by its rudimentary pectoral fins, and its markings of dark transverse bands on a reddish ground. The Solenette (*S. Eutea*) is the smallest British species; it has rudimentary pectorals, and markings like the common sole, with the addition of a black line along every fourth or fifth fin-ray in the dorsal and ventral fins. It is common both in the North Sea and on the south coasts; it does not exceed 5 inches in length. There are a large number of species of Solea in temperate and tropical seas all over the world, but no others are of value as food. There are no soles of any value on the Atlantic coast of the United States. There are numerous closely allied genera. *Synaptura* is distinguished by the continuity of the longitudinal fins with the caudal; it includes the curiously marked East Indian *Synaptura zebra* mentioned by Cuvier, which is reddish olive, with twelve pairs of transverse brown bands. In some species of Solea and allied genera the pectorals are absent altogether. See *A Treatise on the Common Sole*, by J. T. Cunningham (1890).

Solebay. See SOUTHWOLD.

Solecism. A solecism is the term applied to any violation of the grammar or idiom of a language, or of the usages of society. The word (Gr. *Solokismos*) is derived from the city of Soli in Cilicia, whose inhabitants spoke very bad Greek, in consequence of their intercourse with the Cilician natives, and provoked the fastidious Athenians to coin the epithet.

Solen. See RAZOR-FISH.

Solenhofen Stone. See ARCHÆOPTERYX, LITHOGRAPHY.

Solenoid. See MAGNETISM.

Solent, the western portion of the strait that intervenes between the Isle of Wight and the mainland of England, 17 miles long, and about 3 in average breadth, but contracting to $\frac{1}{2}$ mile at Hurst Castle (1535).

Solesmes, (1) a village in the French department of Sarthe, 18 miles NW. of La Flèche, seat of a Benedictine abbey famous in connection with Gregorian music, but suppressed in 1901. The church contains some good sculpture.—(2) A linen-

manufacturing town of Nord, 12 miles E. of Cambrai; pop. 5300.

Soleure (Ger. *Solothurn*), a canton in the north of Switzerland; area, 305 sq. m.; pop. (1920) 130,617, mostly Roman Catholics and speakers of German. The greater portion of the canton is very fertile and well cultivated, especially in the valley of the Aar, but it also embraces outlying ranges of the Alpine and Jura systems. Besides grain, the principal products are fruit, timber, cherry-brandy, cheese, cotton, paper, iron, hose, clocks, &c. The canton consists of the territories acquired by the town of Soleure. The legislative council is elected by the people, and that body chooses the executive (5 members), both for four years. But both bodies are subject to the immediate control of the people, as well as every act they do, by means of the referendum.—The town of Soleure, the capital of the canton, is situated on both sides of the Aar, 18 miles NNE. of Bern by rail. The most notable building is the cathedral of St Ursus (late 18th century), on the site of an older church (10th century), with a cupola and façade of Corinthian columns. There are also a curious old clock tower, an arsenal with a museum of ancient trophies of war, collections of antiquities, and many mediæval houses, &c. There are manufactories of watches and motor-parts. Pop. 13,000. Soleure (*Solodurum*) was a place of some consequence in Roman times, was made a free city of the empire (1218), joined the Swiss Confederation in 1481, and in 1828 was chosen the bishops's see for the diocese of Basel.

Sol-fa System. Attempts have been made at various times to introduce a musical notation in which the staff with its lines and spaces is dispensed with. Jean Jacques Rousseau suggested, but afterwards discarded, a notation where the notes of the scale were indicated by the Arabic numerals—a principle now the chief feature of the French Chev  system. A system similar to Rousseau's in its leading features, called the Tonic Sol-fa, has been brought into use in many singing-schools in Britain and America—its chief promoter being the Rev. John Curwen (q.v.), who obtained his main principles about 1840 from Miss Glover, a teacher at Norwich. The system proceeds on the principle of giving the chief prominence to the fact that there is in reality but one scale in music, which is raised or lowered according to the pitch of the key. The seven notes of the diatonic scale are represented by the Solfeggio (q.v.) syllables, or rather Miss Glover's English modification of them—*Doh, Ray, Me, Fah, Soh, Lah, Te*; *Doh* standing for the keynote in whatever key the music is written. In the early exercises the pupils are accustomed to a scale or diagram, called the Modulator, representing pictorially the exact intervals of a key, with the semitones in their proper places. In written music only the initial letters of the solfeggio syllables are used—*d, r, m, f, s, l, t*; the higher octaves of a given note being distinguished by a ¹ above, as *d¹, r¹*; and the lower by a ₁ or ₂ below, *m₁, m₂*. The name of the key is prefixed to a tune as its signature, as 'Key A,' 'Key B flat'—the keynote being, in all the major keys, *doh*. To indicate

Modulator.

rhythm a perpendicular line | precedes the stronger or louder accent, a colon : the softer accent, and, where necessary, a shorter perpendicular line | the accent of medium force. A note immediately following an accent mark is supposed to occupy the time from that accent to the next. A horizontal line indicates the continuance of the previous note through another pulse or beat. A dot divides a pulse into equal subdivisions. A dot after a mark of continuance indicates that the previous note is to be continued through half that pulse. A comma

indicates that the note preceding it fills a quarter of the time from one accent to the next; a dot and comma together three-quarters. An inverted comma ' is used to denote that the note preceding it fills one-third of the time from one accent to the next. An unfilled space indicates a rest or pause of the voice. A line below two or more notes signifies that they are to be sung to the same syllable. We subjoin an example of the tonic sol-fa shown alongside of the ordinary notation, and illustrating most of the features named :

KEY A.

GOD SAVE THE KING.

In modulating into a new key the note through which the transition is taken is indicated by a combination of the syllabic name which it has in the old key with that which it has in the new—*me lah*, for example, being conjoined into *m'lah*; and in writing this note (termed a bridge note) the initial letter of its syllable, as a member of the old key, is placed in small size before and above the initial of the syllable of the new, as *m'l*, *q's*. In the case, however, of an accidental, where the transition is but momentary, a sharpened note changes its syllabic vowel into *e*, and a flattened note into *aw*, spelled *a*, as *fah*, *fe*; *soh*, *se*; *te*, *ta*. In the minor mode *lah* is the keynote; the sharp sixth is called *bay*, and the sharp seventh *se*. The signature of the key of A minor is 'Key C'; *lah* is A. The time-names of the French Chèvè system have been adopted. The method of teaching, based on a wide experience, is of equal importance to the notation itself.

For a full explanation of this system, see Curwen's *Course of Lessons and Exercises in Tonic Sol-fa*. Its advocates maintain that it possesses advantages over the common system in the facility of its acquisition; the distinctness with which it indicates the keynote and the position of the semitones; the cheapness with which it is printed; and the manner in which, they say, it explains the proper mental effects of notes in harmony and key-relationship, and employs them in teaching. It has, however, been objected to by others, from its withdrawal of the direct indication of both absolute and relative pitch to the eye which exists in the common notation, from its limited applicability to instrumental music, and from its acquirement not being, like that of the ordinary notation, an introduction to the world of musical literature. It presents, however, no barrier, but rather a road to the acquisition of the older notation; and its widespread use and the testimony of the general body of practical teachers are eloquent arguments in its favour. This system practically ousted the 'Fixed Do' system of Hullah, its rival in earlier days.

Solfatara. Volcanoes which are dormant or decadent usually emit steam and various gases, and are then said to be in a *Solfatara stage* in their history. The term is derived from the name of a decadent crater known as the Solfatara in the Phlegrean Fields, near Naples. Sainte-Claire Deville has distinguished the following types: (a) Dry fumaroles, without steam, emitting chiefly anhydrous chlorides at a temperature above 300° C.; (b) acid fumaroles, hydrochloric acid and sulphur

dioxide, with some steam at over 100° C.; (c) alkaline fumaroles, steam and ammonium chloride at about 100° C.; (d) cold fumaroles, nearly pure steam below 100° C.; (e) mofettes, carbon dioxide, nitrogen and oxygen at atmospheric temperatures. *Solfatara*, in a more restricted sense, is applied to decadent vents emitting mainly acid gases, those in which steam is the chief product being called *Fumaroles*, and those giving off principally carbon dioxide, *Mofettes*. Boric acid is extracted in large quantities from some of the fumaroles, known as *Soffioni*, in Tuscany.

Solfeggio, in Music, a vocal exercise, in which the syllables Ut (or Do), Re, Mi, Fa, Sol, La, Si—corresponding to C, D, E, F, G, A, B—are employed in lieu of words. Their use as a method of nomenclature originated, as far as the first six are concerned, in the 11th century with Guido Aretinus (q.v.), who substituted his hexachord system for the old Greek tetrachords. Observing in the melody of an ancient hymn for the festival of St John the Baptist, beginning

Ut queant laxis Resonare fibris
Mora gestorum Famu! tuorum
Solve polluti Labii reatum
Sancte Ioannes,

that the notes on which the successive phrases began were identical in order with the sounds of the hexachord, he adopted the syllables to which they were allied in the above stanza as names to represent the degrees of his new scale. When, early in the 17th century, the octave was completed by the seventh or 'leading note,' the syllable Si, formed of the initials of 'Sancte Ioannes,' was added; while Do generally took the place of Ut, as being more easily sung. The art of thus illustrating the construction of the musical scale by the use of syllables is called *solmisation*.

Solferino, a village of Northern Italy, 19 miles NW. of Mantua, stands on a hill, and has a tower, built by the Scaligers and converted into a museum of the battle, called the Spy of Italy, from which the whole plain of Lombardy may be seen. There, on June 24, 1859, the Austrians were defeated by the allied French and Piedmontese—the first-named losing 21,500 men, and the allies 13,500.

Soli. See SOLEICISM.

Solicitor-general, the name given to one of the law-officers of the crown appointed by patent. The Solicitor-general of England has powers similar to those of the Attorney-general (q.v.), after whom he ranks and to whom he gives aid in discharging

his functions. His tenure of office in practice terminates with the fall of the ministry of which he is a member. He receives on appointment the honour of knighthood.

The Solicitor-general for Scotland is one of the crown counsel, next in dignity to the Lord Advocate (see *ADVOCATE, LORD*), and exercising all his functions along with him, but he does so as his deputy and not of original right. An act, however, of 1887 provides that, if the office of Lord Advocate be vacant, indictments may be raised in the name of the Solicitor-general. Like the Lord Advocate, he has the privilege of pleading within the bar. This right was recognised by the court as early as 1662, though it was afterwards lost for some time.

Solicitors are lawyers, who prepare deeds, manage cases, instruct counsel in the superior courts, and act as advocates in the inferior courts. Their full title is Solicitors of the Supreme Court, and since 1st November 1875 the class includes attorneys, solicitors, and proctors at law. They are deemed officers of court, and the court exercises special jurisdiction over them, committing to prison such of their number as are guilty of misconduct, and in extreme cases 'striking them off the roll'—i.e. erasing their name from the official list of solicitors and so preventing them from practising. By the Solicitors Act, 1919, an application and order for striking a solicitor off the rolls, &c., is made to and heard by a committee of certain members of the council of the Incorporated Law Society appointed by the Master of the Rolls. The committee has power to make any such order as to striking a solicitor off the rolls, or suspending him from practice, as the court or Master of the Rolls formerly had. Before a person is admitted a solicitor he must be articled to a practising solicitor for a term of five years (reduced to three years in certain cases). The Solicitors (Articled Clerks) Acts of 1918 and 1919 make provision for the reckoning of the time of service with the forces, &c., in the Great War, as service of articles. A woman is no longer debarred from being admitted and enrolled as a solicitor. The candidate must pass one general (preliminary) and two legal (intermediate and final) examinations. About £120 in stamp fees must also be paid by the in-entrant. Solicitors in good practice also require a premium (often as much as £600) from each of their articled clerks. After admission a solicitor must take out an annual certificate enabling him to practise. A solicitor must pay for this from £3 to £9 annually. A solicitor of five years' standing may become a barrister on giving one year's notice, passing two legal examinations, and paying certain fees. Penalties are provided for unqualified persons acting as solicitors, and for qualified persons allowing them the use of their name.

Retainer and Authority.—A solicitor is employed by a Retainer (q.v.), which ought to be in writing to avoid after disputes. The exact authority differs in each case, but includes power to compromise the dispute. If once employed in an action he has authority to manage it to the end. A solicitor is liable to his client for gross negligence or gross ignorance; he may often, but not always, protect himself by taking (and following) the advice of counsel. A solicitor is not allowed to make a gain for himself (save the ordinary profits of his profession) at his client's expense, so transactions between them, as sales of property, &c., are very narrowly looked into, nor can he generally take a gift from his client. He cannot be a justice of peace in the county where he practises. He has no right of audience in the supreme court save in bankruptcy matters, and that only before the judge in bankruptcy or a divisional court of King's Bench.

He has certain privileges. Thus, he cannot be made liable for statements honestly made by him as an advocate, and he cannot be forced to reveal written or oral communications made to him by his clients. He is privileged from arrest whilst attending the courts, but this is now of little importance, for it does not extend to punitive attachment.

Remuneration.—The remuneration of solicitors is carefully provided for by various statutes, but often in practice much less than the allowed rate is accepted and much more is exacted. The Attorneys and Solicitors Act, 1870, allows a solicitor to make an agreement in writing for a lump sum or otherwise in lieu of the regular fees. The agreement must be in writing signed by both parties to be binding on the client, but a verbal agreement is binding on the solicitor. The amount agreed on is not payable till the agreement has been examined and approved of by the taxing-master, nor can any action be brought on it. It is enforced by motion before or petition to the proper court. These provisions apply to contentious business. The Solicitors' Remuneration Act, 1881, provides, as regards non-contentious matters, that solicitor and client may agree as to any mode of remuneration. The agreement must be in writing and signed by the party bound by it; it may be enforced or set aside by action, and reviewed under any order for taxation. A solicitor winning a case is entitled to two sets of costs—(a) those between party and party; and (b) those between solicitor and client (extra-judicial expenses in the terminology of Scots law). The first are usually taxed as a matter of course; the other may be taxed on application of either party. A solicitor cannot sue (but may counter-claim) for his costs till one month after he has delivered a signed bill, and except under special circumstances taxation will not be ordered twelve months after delivery of bill. The costs of taxation are paid by the solicitor when more than one-sixth is struck off his charges; if less, the expense falls on the client (see *FEES*).

Solicitors' Lien.—A solicitor has at common law a twofold lien: (1) a general lien on all deeds and papers which have come to him in his professional capacity—but this merely gives him a right of retention till his claims are satisfied; (2) a particular lien (made more effectual by the Solicitors Act, 1860) on property recovered or preserved by his exertions. It may be actively enforced by means of a charging order, which the court will grant him on such property. Collusive agreements between the parties to deprive him of his rights will be set aside. He is not, however, allowed to retain papers so as to prejudice the trial of an action. He must give them up to be held subject to his lien. In Ireland the law is practically the same on this subject as in England.

Scots Law.—In Scotland the term solicitor is so extensively used as almost to have superseded the old designation of writer. The legal expression is Law-agent. This includes Writers to the Signet, Solicitors before the Supreme Courts, and Procurators in the sheriff courts. They must have served five years as indentured apprentices to a law-agent (reduced to three years in certain cases), have passed examinations in law and general knowledge, and been admitted by the Court of Session. By the Law-Agents Apprenticeship (War Service) (Scotland) Acts, 1914 and 1919, periods of service with the forces, &c., in the Great War may be reckoned towards law-agents' apprenticeship. Writers to the Signet, &c., have still certain privileges not here necessary to be discussed. In all cases stamp-duties are paid on admission. Law-agents have a preference, in the nature of a hypothec, over expenses of process, and also a

right, similar to solicitors' lien, to retain property in their hands.

See Cordery's *Law Relating to Solicitors*, Begg, *On Law Agents*, Bowstead, *On Agency* (7th ed. 1924); and E. B. V. Christian, *Solicitors, An Outline of their History* (1925).

Solidity. See MATTER.

Solidus, a Roman gold coin (see NUMISMATICS). The 'solidus aureus' was adopted by the Franks (at 87 to the Roman pound) till the time of Pepin, who suppressed it; but another solidus of silver, or 'solidus argenteus'—the $\frac{2}{3}$ th of the libra or pound—which had been used only as a money of account, was soon after made a coin. In later times this 'sol' or 'son,' like all other coins, underwent an infinity of variations in fineness and value (see LIVRE). On the introduction of the decimal system (1793) into France the sou was abolished, and a piece of five centimes ($\frac{1}{20}$ th of a franc) substituted; but the name continued in common use, and the old sous were retained in circulation. The solidus also appears in the *solito* of some parts of Italy, which was substantially the same as the sou. A trace survives in the s. of £ s. d.

Soliman. See SOLYMAN.

Solingen, a town of Prussia, situated 13 miles E of Düsseldorf and not far from the river Wupper. Ever since the 12th or 13th century it has been famous for its steel and iron ware, especially for sword-blades, helmets, cuirasses, knives, scissors, surgical instruments, &c., which are exported to all parts of the world. Solingen has also iron-foundries, cigar-factories, &c. Pop. (1925) 52,002.

Solipsism (Lat. *solus*, 'alone'; *ipse*, 'self'), a philosophical term denoting in *ethics*, according to its first usage, by Kant, moral egoism, self-seeking, making one's own self the end of all one's actions; in *metaphysics* the doctrine that the self and the self's ideas are all that exists; in *epistemology* the theory that knowing being a subjective process, what is known must always be either the self or some modification of the self; negatively that nothing can be known except the self and its modifications or states; in *methodology* such principles as that in an inquiry a distinction must be drawn (a) between the individual's own experience and that of others, the testimony of others being excluded, and for each individual his own sense-data being the only evidence admitted (see Bertrand Russell, 'Sense-data and Physics' in his *Mysticism and Logic*, 1918); or (b) between actual phenomena and hypothetical entities assumed as causes or grounds for phenomena (see Hans Driesch in his *History and Theory of Vitalism*, 1914). The ethical Kantian use is not now current. In its metaphysical and epistemological senses the word really signifies an extreme form of subjective idealism. And properly the term cannot be applied to theories like Berkeley's, which, while denying the independent existence of an external material world, yet allow that some reality in addition to the individual subject exists. See s.v. 'Solipsism' in *Dictionary of Philosophy and Psychology* (ed. Baldwin), and in *Encyclopædia of Religion and Ethics* (ed. Hastings).

Solis, JUAN DIAZ DE, Spanish navigator, was born at Lebrija, between Cádiz and Seville, near the middle of the 15th century. He was sailing along with Pinzon when the latter discovered (1499) the mouth of the Amazon. In 1515 he himself was sent out, in command of three ships, to find a sea-passage through the American continent that should lead to the East Indies. This led to his discovery of the Paraná (i.e. the Río de la Plata). But he suffered himself to be drawn into an ambushade by the warlike Charruas, who dwelt on its banks, and was killed by them (1516).

Solitaire (*Pezophaps solitarius*), a bird allied to the dodo, and like it now exterminated. It lived on the island of Rodriguez, and was described by Leguat, a Huguenot refugee, who in 1691 settled with a small colony on the island. In his *Voyages et Aventures* Leguat describes the solitaire as a large bird, the male sometimes weighing 45 lb.; taller than a turkey, the neck a little longer in proportion, and carried erect; the head of the male without comb or crest, that of the female with something like a widow's peak above the bill; the wings small, and the bird incapable of flying, but using the wings to flap itself or to flutter when calling for its mate, or as a weapon of offence or defence; the bone of the male's wing thickened at the end so as to form a round mass about the size of a musket-bullet; a roundish mass of feathers instead of a tail; the plumage very full and beautiful. On open ground it could be outgun by a man; and its flesh was very good to eat. In 1865 Newton visited Rodriguez and discovered abundant remains of the solitaire; since then more skeletons have been discovered, and the osteology of the bird is now well known. The figure here given is derived from a rude cut in Leguat's work.

Solitaire
(*Pezophaps solitarius*).

See Strickland and Melville, *The Dodo and its Kindred* (1848); also Newton's *Dictionary of Birds* (1897).

Sollum, a small town on a gulf of the same name in the north coast of Africa, in the north-west corner of Egypt towards Tripoli. It was occupied by an Anglo-Egyptian force on the Italian occupation of Tripoli in 1911.

Solmisation. See SOLFEGGIO.

Solmona. See SULMONA.

Solo, in music a voice or instrument that is to perform alone or in a more prominent manner, as *soprano solo*, *violin solo*; also a composition for a single instrument accompanied.

Sologne, a sandy, unfertile, rye-growing region (*secalumia*, from Lat. *secale*, rye) in north-central France, on the upper basin of the Loire (Loiret, Loir-et-Cher, Cher); see FRANCE.

Sologub, FEDOR, pseudonym of Fedor Kuzmich Teternikov, Russian writer, born in 1863, and educated at St Petersburg. He wrote many tales, fables, fairy-tales, and poems, some of which (*The Created Legend*, *The Little Demon*, *The Old House*, &c.) have been translated into English.

Solomon (Salomon, Salomo, Suleimán, Solyman; Heb. Shēlōmō, from *shālēm*, 'peace,' and so meaning 'the Peaceful,' like Ger. Friedrich), the second son of David and Bathsheba, successor of the former on the throne of the Israelitish kingdom for forty years (c. 970-933 B.C.). See JEWS, Vol. VI. p. 331. In later Jewish and Mohammedan literature Solomon appears not only as the wisest of men, but as gifted with power to control the spirits of the invisible world. As the builder of the Temple his name is much quoted in the literature of Freemasonry (see FREEMASONS). For the so-called Song of Solomon, see CANTICLES; for the other biblical works long attributable to Solomon, see BIBLE, ECCLESIASTES, PROVERBS. The *Wisdom of Solomon*, one of the books of the Apocrypha (q.v.) makes a claim, real or hypo-

thetical, to have been written by Solomon, but from internal evidence it is obviously the work of an Alexandrian Jew, written in the period 150–50 B.C. The book is a hymn in praise of Wisdom—the Wisdom of Proverbs (q.v.), but containing approximations to the doctrine of the Logos (q.v.), and combines the ethical doctrine and speculation of the Hebrews with Platonic and Stoic philosophy. There are commentaries on it by Greug (1909) and Goodrick (1913). The *Psalms of Solomon*, also called the *Psalms of the Pharisees*, were apparently written in Hebrew by a Pharisaic Jew in Jerusalem about 70–40 B.C., and are a protest against modern corruptions. They are an imitation of the canonical psalms, and of interest for their Messianic passages (see Gray in Charles, *Apocrypha*, vol. ii., 1913). Later still are the *Odes of Solomon* (edited by Rendel Harris), consisting of forty-two mystical hymns, part Christian and, possibly, part Jewish; they were known to the Gnostic book *Pistis Sophia*. See Moncre D. Conway, *Solomon and the Solomonite Literature* (1900).

Solomon Islands, an archipelago 500 miles E. of New Guinea, stretching SE. in two parallel chains for 600 miles towards the Santa Cruz group. The north-eastern chain embraces Bougainville, Choiseul, Ysabel, and Malaita; the south-western Vella Lavella, Kulambangia, New Georgia, Guadalcanar, and San Cristoval. Besides these, which vary between 70 and 110 miles in length, and are 20 to 30 in width, there are a number of smaller ones. They have a total estimated area of 15,000 sq. mi.; are nearly all of volcanic formation, there being two active volcanoes and several quiescent and extinct volcanoes; and are covered from the seashores to the summits of the highest mountains (10,000 feet in Bougainville, 8000 in Guadalcanar, 4100 in San Cristoval) with dense tropical vegetation. There is an extraordinarily heavy annual rainfall, estimated by Dr Guppy at 400 and even 500 inches on the mountains, and 150 on the coasts. The atmosphere is consequently very moist; and the temperature ranges from 75° to 95° F. The people, believed to number about 200,000, show decidedly Papuan or Melanesian characteristics; they are divided into a great number of tribes, constantly at war with one another, and are very suspicious towards strangers. Cruel and savage, they indulge in cannibalism, wear little or no clothing, and tattoo their bodies. Their religion is a kind of ancestor-worship, with attendant mysteries. Totem castes exist on Guadalcanar and some others of the islands. Yams, vegetables, and the coconut are the principal productions used for food. The fauna of the islands includes a phalanger (cuscus or flying-fox), bats, gigantic rats and frogs, very large and very brilliant butterflies. This group was discovered by the Spaniard Mendaña in 1567. Then for two hundred years it was never visited by Europeans, and was virtually rediscovered (1767–88) by Carteret, Bougainville, Surville, Shortland, and other navigators. Bougainville and Buka (formerly Geiman) are under Australian mandate; the rest form a British protectorate.

Solomon's Seal (*Polygonatum*), a genus of Liliaceæ, differing from Convallaria or Lily of the Valley (q.v.) chiefly in the cylindrical tubular perianth, and in having the flowers jointed to their flower-stalks. There are three British species. The Common Solomon's Seal (*P. multiflorum*) is found in woods and copses in many parts of England and in a few places in Scotland. It has a stem about two feet high, the upper part of which bears a number of large, ovate-elliptical, alternate leaves in two rows. The flower-stalks are generally unbranched; the flowers not large, white,

and drooping. The roots are knotty, and a transverse section of them reveals characters which the fanciful have imagined represent the impress of the famous seal of Solomon, to which very ancient legends attributed magical properties; the appearances on the cut root being variously described as looking like the 'marke of a seale,' like the magical Pentacle (q.v.), or like Hebrew letters. The

Narrow-leaved Solomon's Seal (*P. verticillatum*) is a rare British plant, only found in a few places in Scotland and England. The leaves are whorled. The Angular or Sweet-smelling Solomon's Seal (*P. anceps* or *officinale*) is also rare in Britain, and is found only in England. It more nearly resembles the Common Solomon's Seal, but is smaller, and has greenish, fragrant flowers. All these species are common in many parts of Europe. They are very similar in their properties. In America there are *P. giganteum*, 2 to 7 feet high, and a smaller *P. biflorum*. The young shoots of *P. officinale* are eaten by the Turks like asparagus. The root is white, fleshy, inodorous, with a sweetish, mucilaginous, acrid taste. It contains *Asparagin*. It is a popular application to bruises, to prevent or remove discoloration, and its use is well known to those who are too apt to get a black eye now and then. A kind of bread has been made of it in times of scarcity. The berries are emetic and purgative.

Angular-stemmed Solomon's Seal (*Polygonatum officinale*).

Solon, the famous lawgiver of ancient Athens, was born probably about 640 or 638 B.C., and died about 558 or 559. His father, Excestides, who traced his descent from the royal family of Attica, had squandered an ample fortune. His son became a trader, an occupation which at once brought him wealth and opened up rich stores of observation and experience to his inquiring mind. Doubtless to the wide extent of his travels must be ascribed that unprejudiced political genius by which he was to create a constitution such as had never existed in the world before. He was known also as a writer of graceful and amatory verses, but later his muse soared to a higher strain and sang the triumphs of his legislation and the blessing of the gods on his reforms. One of the finest of his elegies owes its preservation to its being quoted by Demosthenes in his *De Falsa Legatione* (sects. 286–289), 'to show (as he says) how Solon hated fellows like Æschines;' several quotations—one of twenty lines otherwise unknown—occur in Aristotle's *Constitution of Athens* (first edited from a papyrus acquired by the British Museum, by F. G. Kenyon, 1891). The Megarian war (610–600) saw the occasion of Solon's first political achievements. The sarcasms of his stirring Tyrtean verse induced the desponding Athenians to continue the struggle, and Solon was placed at the head of an expedition to Salamis. Suddenly landing there, he drove out the Megarian garrison, and won the 'lovely island' for Athens; finally the dispute was settled by the arbitration of Sparta in favour of Athens. No story of antiquity is better known than that which tells how Solon attempted to

influence the award by the insertion of a line in the *Iliad* (ii. 558), which speaks of the Salaminian Ajax ranging his ships with the Athenians. Solon's influence, already wide, was increased by the strong position he took up a little later in behalf of the Delphic oracle against its oppressors. But the unholy murder of Cylon still rested as a stain upon Athens; Nisæa and Salamis were again lost; and superstitious fears took hold of the people.

But the distress of Attica was not so much religious as economic. The particular grievance which brought matters to a head was the law of debt. The want of a middle class made the contrast between the opulence of the nobility and the indigence of the poor more glaring. A desperate conflict was imminent, when in 594 both parties concurred in inviting the poet and devoted patriot, Solon, to assume the archonship and pacify his distracted country. 'It is not the will of the gods that our city should perish,' sang the poet in noble numbers; 'it is the desire of gain which will bring us to ruin; the thoughts of our leaders are not honest, and their greed will bring great evils upon them. Many of the poor go into foreign lands, sold as slaves, and burdened with shameful bonds.' His first measure was the famous *Seisachtheia*, and the remedy was severe. A limit was placed on vast accumulation of lands, the person of the debtor was safe whatever his obligations, mortgaged land was restored, debts were cancelled. The reform of the money-standard was made, not to assist debtors by reducing their debts (73 of the old drachmas were recoined into 100 of the new), but to simplify trade with Asia Minor and open up new fields for Athenian enterprise. Then the poet sang the end of his labours: 'Many citizens who had been sold into slavery I brought back to Athens their home; some of them spoke Attic no longer, their speech being changed in their many wanderings. Others who had learned the habits of slaves at home, and trembled before a master, I made to be free men. All this I accomplished by authority, uniting force with justice, and I fulfilled my promise.' On laying down office at the end of the year he was requested to reform the entire political constitution of Athens. Solon's object was to destroy the power of the Gentes, and give the poorest class some control over the officers and the law. On the division of the people into four classes, rated according to income, a division which our latest authority, the *Constitution of Athens*, assigns to Draco, his reforms were based. The first class (*Pentakosiomedimnoi*) were such as possessed an annual income of not less than 500 medimni of corn, the second class (*Hippeis*) were rated at 300, the third (*Zengitai*) at 200, the fourth (*Thêtes*) consisted of all below the *Zeugitai*.

On each of the four certain duties were imposed. The three highest provided the land army of Attica, while the *Thêtes*, as rowers in the triremes, formed the most important part of the navy, one day to prove the salvation of Greece and the mainstay of the Athenian empire. The chief officers of state were restricted to the *Pentakosiomedimnoi*; the second and third classes were eligible for minor functions. If the *Thêtes* were not admitted to office, their inclusion in the Attic tribes or *phylæ*, their new right of sitting in the Assembly, electing the public magistrates and passing sentence on their conduct at the end of their year of office, made them practically the sovereign power in the state; and Aristotle traces the swift development of Athenian democracy to the judicial powers received from Solon. The *Boulê* of 400, another of the great lawgiver's creations, was formed by the election of 100 members from each tribe, and took the place of Draco's council of 401, of which we first learn also in the Aristotelian papyrus. The democratic tendency of Solon's Council proved by

its subsequent history was perhaps accidental. The Areopagus continued as before to be the guardian of the laws and public morals; it decided also on all grave criminal cases. If he did not originate it, Solon saw the wisdom of preserving and strengthening a body which, by its nature, comprised the best representatives of the highest class of citizens. 'It was,' says Eschylus, 'the bulwark of the land and city, the like of which no man had seen either in Scythia or in the island of Pelops; a council incorrupt, awful, and severe; a watchful guardian over those who slept.' The last of his political reforms was the institution of the *Heliaia* or popular court of law, the members of which were men of more than thirty years of age chosen annually by lot from every class. The object of its creation was to serve as a balance to the Areopagus, whose judicial supremacy might go too far in the interests of the aristocracy who composed it.

The laws of Draco were not suited to a more civilised age; not only was the severity of punishment for infringement out of all proportion to the offence, but Draco's conception of law appeared inadequate to the comprehensive views of Solon, to whom the function of law was contained not less in directing the citizen's most intimate relations and arrangements than in the guidance of his political and public conduct. Solon's regulations ranged over every province of life. All Draco's laws were repealed except those relating to murder. A limit was placed on the quantity of land that might be held in Attica; no citizen could be enslaved for debt, and absolute freedom in bequeathing property was ensured to any citizen who died childless. Arbitrary power of fathers over their children was restrained and arbitrary disinheritance forbidden. Any citizen who maintained neutrality in a sedition lost his civic status. The Areopagus was empowered to deal severely with luxury in food and dress. No woman might leave home with more than three changes of clothing, or with a basket of more than a cubit's length, and excessive walling at funerals was forbidden. The laws, inscribed on wood, were placed in the Acropolis, whence they were removed to Salamis during the Persian wars.

The later years of Solon belong more to legend than to history. We are told that he left Athens for ten years, after binding the Athenians by oath to observe his laws till his return. His travels took him far afield. Cyprus, Asia Minor, and Egypt, probably the scenes of his early career, were revisited. Historical investigation may deny the possibility of a dialogue between Solon and Croesus, but cannot spoil the charm of a story which Herodotus has rendered immortal. The king, then at the height of his prosperity, was said to have asked him who was the happiest man in the world, expecting to hear himself named. Solon first mentioned Tellos, an Athenian who had died for his country at Eleusis. Nor could Croesus obtain the second mention in the ranks of the happy; that place was assigned to two Argive youths, Cleobis and Biton, to whom the gods had given to die in their sleep as the reward of an act of filial piety. The wrath of Croesus at the moment was unrestrained, but bitter experience taught him to appreciate the wisdom of Solon, and 'to account a prosperous man happy only when he ended his life as he began it.' Solon's meetings with Anacharsis and with Thales, one of the seven wise men like himself, were among the moral apologues of the ancients. The last years of Solon were passed at Athens, where the wild conflict of parties disturbed the application of the new constitution. He saw the failure of his plans with the deepest distress. His suspicion of his kinsman Pisistratus was justified by the issue. Again he

entrusted his warnings to elegiac verse: 'Fools, ye are treading in the footsteps of the fox; can ye not read the hidden meaning of these winning words?' The protest was in vain; Pisistratus seized the government. The opposition of Solon continued; undeterred he laid down his arms before his door, and called heaven to witness that he had stood by his country. Retiring into private life he died soon after the usurpation of Pisistratus, with the last injunction that his ashes should be scattered over the island of Salamis, the 'lovely island' which had been the scene of his earliest exploit.

Solon died the subject of a despotic monarch. His labour might seem wasted, but its eclipse lasted only for a season, and even during the years of the tyranny of Pisistratus its influence was strong. Morally and politically a power among his countrymen, Solon saw that to imprison men in a relentless political machine like Lycurgus, and to humble a refined aristocracy beneath a proletariat without political training, were policies equally dangerous. His constitution was a graceful compromise between democracy and oligarchy. 'He would have men equal before the Goddess of Justice, though not in the councils of the state,' says Mr Adcock. As it happened, his reforms proved a stepping-stone towards democracy. In poetry he represents a high Ionian type; as a traveller and a soldier his experience of men was large. In the higher realms of constructive statesmanship he rivals the greatest legislators not only of Greece but of the world.

See Lehmann-Haupt, *Solon of Athens* (1913); Linforth, *Solon the Athenian* (with poems and commentary, 1919); Adcock in *The Cambridge Ancient History*, vol. iv. (1926), chaps. ii., iii.; the standard histories of Greece; and the various editions and translations of Aristotle's *Constitution of Athens*, and of Plutarch.

Solothurn. See SOLEURE.

Soloviev, VLADIMIR (1853-1900), the 'first Russian philosopher,' was born at Moscow, son of Sergei Soloviev (1820-79), historian of Russia. He wrote *Justification of Good* (trans. 1918), &c. See study by Séverac (1912).

Solstice (Lat. *solstitium*, from *sol*, 'sun,' and *sto*, 'I stand'), that point in the ecliptic at which the sun is farthest removed from the equator, and where it is consequently at the turning point of its apparent course. There are two such points in the ecliptic, one where it touches the tropic of Cancer, the other where it touches that of Capricorn. The former is the summer, and the latter is the winter solstice to those who inhabit northern latitudes, and *vice versa*.—The term is also employed to signify the time at which the sun attains these two points in its orbit, the 21st of June and about the 21st December.

Solution, a homogeneous mixture of two or more substances, which are not separated into constituents by mechanical means without altering the state of one of the substances, and whose properties vary with the properties of the constituents. According to this definition it is possible to have a solution of a solid in a liquid, a solid in a solid, or a liquid in a liquid. The substance dissolved is termed the solute and the substance in which it is dissolved is termed the solvent. The solubility of different substances in various solvents differs within wide limits, but it is usually increased by rise of temperature and by increase of pressure. In the case of crystalline bodies there is a limit of solubility for a given temperature, and when that limit is reached the solution is said to be saturated at that temperature. In the case of liquids there are many examples of mutual solubility—e.g. if water and ether are shaken together and allowed to stand, they separate into two layers, the upper one con-

sisting of ether with dissolved water, and the lower one of water with dissolved ether. When a solid is dissolved in a liquid, heat is absorbed as a rule. The exception being in those cases where chemical action takes place between the solvent and the solute, when heat is given out. The freezing point of a solution is always lower than that of the solvent, whilst the boiling-point is higher, the differences in both cases being directly proportional to the concentration of the solution. If the molecular weight in grams of any non-electrolyte is dissolved in a litre of water the depression of the freezing-point is a constant; if, however, the solute is an electrolyte, then the depression is always greater than theory demands; a similar difference is noted in the boiling-points. The explanation generally accepted by chemists of this anomalous behaviour of electrolytes, is that an electrolyte on solution in water splits up into separate particles termed ions, and that up to a point the ionisation increases with dilution—for example, if salt is dissolved in water it is no longer salt but ions of sodium and chlorine. This theory is known as the ionic theory, and whilst it explains most of the phenomena of solution there are cases where it fails.

Solutrean. See STONE AGE.

Solway Firth—in its upper part best regarded as the estuary of the river Esk, in its lower as an inlet of the Irish Sea—separates the north-west of Cumberland from the south of Scotland. Its entire length, until lost off Balcarry Point in the Irish Sea, is 36 miles; its breadth for the first 13 varies from $1\frac{1}{2}$ to 8 miles, but afterwards it gradually, although irregularly, increases to 22. The principal rivers flowing into it, besides the Esk, are the Annan, Nith, Dee, and Urr from the north or Scottish side, and the Eden and Derwent from the south or English side. The most striking feature of the Solway Firth is the rapidity with which its tides ebb and flow. The spring-tides are peculiarly swift and strong—the bore rushing in from 3 to 6 feet high, and at the rate of 8 to 10 miles an hour, occasionally inflicting serious damage on the shipping; while after it has retreated great stretches of the bed of the firth are left bare, and in some places one can even cross over from the English to the Scottish shore. The salmon-fisheries of the Solway are valuable. Near Annan the Solway is spanned by a railway viaduct, 1960 yards long, which, originally constructed in 1866-69 at a cost of £100,000, was almost destroyed by floating ice in January 1881, but was reopened to traffic in 1884. Scott paints the scenery of the Solway Firth in both *Guy Mannering* and *Redgauntlet*.

Solway Moss, a district of Cumberland about 7 miles in circumference, lying west of Longtown, and immediately adjoining Scotland. As its name implies, it was once a bog, but it is now drained and cultivated. It is historically notable as the scene in November 1542 of the rout of a Scottish host under Oliver Sinclair by a handful of English borderers under Thomas Dacre, the 'Bastard of Lanercost,' and Jack Musgrave of Bewcastle. Here, too, on 13th November 1771, an extraordinary disaster occurred. The boggy ground, surcharged with moisture—the effect of heavy rains—rose, swelled, and burst like a torrent, sweeping along with it trees and houses, and destroying some thirty small villages.

Solyman, or SULEIMAN II. (or I.), called 'The Magnificent,' the greatest of the Ottoman sultans, was born in 1496, and at twenty-four succeeded his father Selim I. His first care was to refund a large amount of property that had been unjustly confiscated, his next to remove incompetent and corrupt officials, and to begin a comprehensive scheme of

internal reform. But before this task was completed he led an army into Hungary, to extort the tribute that its king refused to pay him at his accession. He took Schabatz (Sabac), Semlin (Zemun), and Belgrade (1521), and left Turkish garrisons in them. Then he carried a very formidable army to attack the Knights of St John at Rhodes; they had beaten off a Turkish army with a loss of 25,000 forty years previously. On this occasion they inflicted a loss of nearly four times that number upon the Turks before surrendering (1523) after a six months' siege. The following three years were devoted by Solymán to the internal government of his domains. But in 1526 he again led a force of 100,000 men into Hungary, slew King Louis at Mohacs (29th August) and all but annihilated his army, and pushing on farther captured both Buda and Pesth. He was recalled by tidings of an outbreak in Asia Minor. By 1529, however, he was back again in Hungary, ostensibly as the supporter of John Zapolya, who claimed the crown of Hungary against Ferdinand of Austria. Ferdinand was turned out of Buda and driven back into Vienna, which city the sultan besieged (September to October). After delivering a desperate assault, which cost him 40,000 soldiers, he was obliged to retreat without taking it. Returning home he directed his aims against Persia, and conquered (1534) large portions of Armenia and Persia proper, including the strong cities of Tabriz and Bagdad. At the same time he sent out his fleets against the Christian powers of the Mediterranean, and his lieutenants (Barbarossa, Piyala, and others) conquered the whole of the north of Africa except Morocco—Egypt was his already. But Tunis was recovered by Charles V. in 1535. In 1542 the widow of John Zapolya appealed to Solymán to aid her son against Ferdinand. Solymán allowed the young prince to retain Transylvania, but Hungary he kept for himself. Six years later a truce was made between the Turks and imperialists, Solymán being left in possession of the greater part of Hungary and Transylvania, and being granted a yearly tribute of 50,000 ducats. In 1565 the fleet and army of Solymán sustained a severe reverse in an unsuccessful attempt to reduce Valetta, the headquarters of the Knights of St John in Malta. And in the following year, whilst besieging the small fortress of Szigeth in Hungary, the great sultan died (4th September). Solymán is equally renowned as a lawgiver and just ruler, as a patron of learning and an encourager of the fine arts.

Soma in Indian literature, Haoma in the *Avesta*, is the name of a drink, pressed (*su*, 'press out'; cf. *śu*) from a plant, and mixed with milk. The intoxicating qualities of the drink won it great popularity in Indo-Iranian times, but the Zoroastrian reform was hostile to this as to other aspects of nature-worship. In India, on the other hand, the Soma cult became of the highest importance; the effect of the drink on its votaries is effectively described in one hymn of the *Rigveda*: 'We have drunk the Soma; we have become immortal; we have won the light; we have won the gods. What can enmity do to us now? What the malice of mortals, o immortal?' Naturally the exhilaration caused by the drink led to its being treated as divine, and the god Soma appears already in the *Rigveda* as a most potent power, mighty to heal the sick, make the blind see, the lame walk. As Indra drinks deep draughts of Soma to strengthen him to win the rains from the demons who hold them back, so Soma as a god is a mighty warrior, who wins for his votaries cows, chariots, horses, gold, heaven, countless boons. Moreover, he is a guardian of natural order, supporter or creator of heaven and earth, and he inspires the poet to new songs. Nonetheless he is present and identified

with the drink or the plant; he grows on the mountains, but also he is brought down to earth by an eagle, perhaps the lightning. In the later Vedic period he is constantly identified with the moon, which is conceived as the heavenly receptacle of the Soma which the gods drink, an idea suggested in part by the waxing and waning of the luminary; the effort to show that this is an early idea may now be regarded as disproved. The theologians of the Brāhmaṇas allude to the drinking of Soma and the pounding of the stalks to obtain the juice as the eating and killing of the god; but this conception appears with them to be little more than a priestly fancy, not a vital popular belief. The use of substitutes for the real Soma is in this period frequently mentioned, whence it is probable that the true Soma grew only in the mountainous regions once inhabited by the Indo-Iranians. This may help to explain the fact that the cult, evidently extremely popular in Vedic times, plays no serious part in mediæval or modern Hinduism, though even now it is not entirely extinct. The plants now used by Brāhmaṇas of the Deccan, as also by Parsees of Kerman and Yezd and of Bombay, are species of *Asclepiads*, akin to the common milk-weed, but identity of any of these with the Vedic Soma is most improbable. As practised in later Vedic times, the Soma sacrifice is accompanied by an elaborate ceremonial, and an animal sacrifice forms an essential preliminary. Sixteen priests, with assistants, officiate; Soma shoots are purchased for a cow from a low-class vendor, who is then beaten from the place of sacrifice with sticks, doubtless a primitive dramatic ritual symbolising the acquisition of the plant from the demons who seek to hold it back. The shoots then are treated as embodying Soma the King; he is taken in state to the sacrificial hut, placed on a throne, offered the usual guest-meal of honour. The juice is obtained by pounding or pressing, and libations are made in the morning, at midday, and in the evening. The rite may be carried on for prolonged periods, and an essential feature is the drinking of the liquor, mixed with various ingredients, by the priests. The hymns used at the rite are in large part found in Book ix. of the *Rigveda*, which consists of hymns composed for the purpose of honouring *Soma pavamāna*, i.e. the Soma as it becomes clear.

See Eggeeling's trans. of the *Satapatha Brāhmaṇa* (S.B.E., xii. and xxvi.); Macdonell, *Vedic Mythology*, Keith, *Religion and Philosophy of the Veda*.

Somali-land, an eastern projection of Africa, washed by the Gulf of Aden on the north and by the Indian Ocean on the south-east; the western boundary may be defined by a line drawn south from the Strait of Bab-el-Mandeb, through Harar to the river Jub or Juba. Besides this river the only considerable stream is the Webi-Shebeyli, which, however, does not reach the Indian Ocean, its waters being lost in the sands near the southern extremity of the region. The country is an undulating plateau, in very many parts parched and barren; though in the rainy seasons (two of two or three months' duration each) numerous swamps are formed. Game and wild animals—elephant, hippopotamus, lion, leopard, antelopes, water-buck, monkeys, ostriches, vultures, marabout storks, crocodile, &c.—are generally plentiful. The vegetation is on the whole arid. The nomad Somal, found also in the British colony of Kenya, have herds of camels, sheep, and oxen, and keep horses and goats. They are Mohammedans of Hamitic stock, closely akin to the Galla and the Abyssinians; but they are not a pure race, for there is a strong blending of Arab blood in them, with easily discernible traces of Negro. What trade there is in the natural products of Somaliland (myrrh

and frankincense, hides, ostrich-feathers, coffee, salt, &c.) finds an outlet through Berbera, Zeyla, and Jibuti. — FRENCH SOMALILAND (Côte des Somalis), has a population of 200,000. From the capital, Jibuti, which has superseded Obok, a railway runs to Die Dawa and Adhis Ababa in Abyssinia. — THE SOMALI COAST PROTECTORATE of Britain, which involved a troublesome military expedition into the interior against the Mullah Abdulla in 1902-4, extends from Ras (Cape) Jibuti, west of Zeyla, to long. 49° E., and includes the towns of Zeyla, Berbera, Bulhar, and Karam. Annexed by Egypt in 1875, this territory has been under British protection since 1884. An arrangement with Italy in 1894, and with Abyssinia in 1897, delimited the British protectorate (68,000 sq. m.; pop 300,000). British posts were withdrawn from the interior in 1910. The Mullah held half of the protectorate in the Great War, but was overcome in 1920. — The colony and protectorates of ITALIAN SOMALILAND (140,000 sq. m.; pop. 400,000) consist of the coast region from near Bandar Ziyada to Cape Guadafui, and then to the Jub, with a hinterland acquired (1897-1908) by agreements with Abyssinia, and a strip beyond the Jub ceded by Britain in 1925. With British Somaliland it shared the troubles of the Mullah movement.

See F. L. James, *The Unknown Horn of Africa* (1888); Wolverton, *Five Months' Sport in Somali-land* (1894); Swayne, *Seventeen Trips Through Somaliland* (1895); Donaldson Smith, *Through Unknown African Countries* (1897); E. N. Buxton, *Short Skulks* (1898); F. B. Pearce, *Rambles in Lion-Land* (1898); Drake-Brockman, *British Somaliland* (1912); Jardine, *The Mad Mullah* (1923); and for the Somali (non-Bantu) language, the grammar and English-Somali dictionary of the Franciscans Larajasse and Sampont (1898), and Kirk's Grammar (1905).

Sombor. See ZOMBOR.

Sombrerete, a town of Mexico, 105 miles N.W. of Zacatecas, famous for rich silver-mines; pop. 10,000.

Sombrero (Span. *sombra*, 'shade'), a broad-brimmed felt hat common in parts of America. — For Sombrerite, see APATITE.

Somers, SIR GEORGE (1554-1611), an English navigator, born at Lyme Regis, whose shipwreck on the Bermudas (q.v.) led to their colonisation from Virginia by him in 1611.

Somers, JOHN, LORD, Whig statesman, was born at Worcester, an attorney's son, on 4th March 1652, and in 1667 entered Trinity College, Oxford, in 1669 the Middle Temple, being called to the bar in 1676. Associated with the 'Country party,' he was one of the counsel for the Seven Bishops (1688), and from the Revolution onwards took a prominent part in politics, being returned for Worcester to the Convention parliament, and successively made Solicitor-general, Attorney-general, and Lord Keeper of the Great Seal, until in 1697 he became Lord Chancellor, and was raised to the peerage as Baron Somers of Evesham. He was William's most trusted minister, and as such was the object of frequent attacks, one of which in 1700 resulted in his being deprived of the seal, and another in 1701 in an impeachment by the Commons, rejected, however, by the House of Lords. He returned for two years to power as President of the Council (1708-10), and died of apoplexy, 26th April 1716. The *Somers Tracts* (16 vols. 1748), a valuable collection of state papers from his library, were re-edited by Sir Walter Scott (13 vols. 1809-15).

Somersby, a pretty village of Lincolnshire, stands on the Wolds, about 7 miles E. by N. of Horncastle and the same distance N.W. of Spilsby, and is celebrated as the birthplace of Tennyson.

The rectory, in which he was born, is an ordinary country parsonage, not without touches of picturesqueness.

Somerset. DUKES of See SEYMOUR. For Robert Carr, Earl of Somerset, see OVERBURY.

Somerset House, London, fronting both on the Strand and on the Thames Embankment, stands on the site of a palace built by the Protector Somerset about 1549, which fell to the crown on Somerset's execution. The original edifice was pulled down and rebuilt in 1776-86 after designs by Sir William Chambers, in the Palladian or Italian style. The building accommodates the offices of the Inland Revenue, Wills and Probate, the Registry-general of Births, Deaths, and Marriages for England and Wales, and other departments.

Somersetshire, an important maritime county in the south-west of England, is bounded on the N. and W. by the Bristol Channel (the ancient 'Severn Sea'); by Gloucestershire, Wiltshire, and Dorsetshire on the NE. and E.; and by Devonshire on the S. and SW. In form oblong, with a length of some 80 miles and a breadth of 36, it has an area of 1620 sq. m. Pop. (1801) 273,577; (1891) 430,050; (1911) 458,025; (1921) 465,682. The surface is exceedingly diversified, with every variation from lofty hills and barren moors to rich vales and wide marshy levels, whence the sea is banked out by an elaborate system of dykes and sluices. The frontier between Somerset and the adjacent counties consists for the most part of a broken and picturesque hilly district. Sundry ranges of hills, running east and west, give to the county its leading physical characters. Chief of these is the Mendips (q.v.), which stretch from near the city of Wells to the coast at Brean Down, with a seaward continuation in the islets of the Steep and Flat Holms. South of the Mendips lies the great alluvial plain of central Somerset, broken by the line of the Polden Hills, which rise from the marshy levels like a long low island some 300 feet. Still farther south, beyond Taunton, are the Blackdown Hills, about twice this elevation, and continuing eastward into the broken upland which once formed part of the ancient forest of Selwood, where Somerset, Wilts, and Dorset meet. To the north-west of Taunton, bordering Bridgwater Bay, are the Quantock Hills, rising at Will's Neck to 1262 feet; and west, again, is the wild district of Exmoor Fores (q.v.), partly in Devon, but mainly in Somerset. At several points on the inland borders heights of between 800 and 1000 feet are attained. The only two rivers of commercial importance in Somerset originate elsewhere. The Bristol Avon, which forms the boundary of the county for many miles, rises near Badminton in Wilts, and enters Somerset near Bath. The Parret rises near South Perrot in Dorset, and drains the middle of the county: it is tidal to beyond Bridgwater, and is one of the streams possessing a tidal 'bore.' These two rivers with their feeders discharge the bulk of the waters of the county. Between them the chief independent streams are the Axe and the Brue, south of the Mendips, and the Yeo, north. The Exmoor district is drained by the Exe, which falls into the sea at Exmouth, and by the Devonshire Axe, which rises, however, in Dorset.

The geological features of the county are singularly varied, ranging from Devonian upwards. Carboniferous strata occupy a wide area in the north, east, and centre, and are worked for coal in the Radstock and Nailsea basins of the Bristol coal-field; while the mountain-limestone is largely developed in the Mendips and near Bristol, where it is traversed by the magnificent gorge of the Avon. Oolitic rocks stretch along the east of the

county from Yeovil to Bath, and in the neighbourhood of the latter city are extensively worked for the production of the well-known Bath building-stone; while other beds are wrought at Doulting and Ham Hill. Liassic rocks are well developed, chiefly in the central region, though in somewhat scattered fashion. Triassic rocks occupy a very wide area in the west of the county, ranging with breaks from Wellington to Bristol; and there is Greensand on the extreme south-west. Extensive caverns in the limestone of the Mendips have yielded abundant remains of prehistoric mammalia, with relics of their human contemporaries. The Mendip mining area is one of the oldest in the kingdom, for lead was raised there before the advent of the Romans, and the iron ores of the Brendon Hills, on the eastern flank of Exmoor, were also worked at a very early date.

The agriculture is mainly pastoral, the proportion of tillage to grazing and dairy-farming being small, though the low lands generally are exceedingly fertile—the fertility of the valley of the Tone, near Taunton, having passed into a proverb. Even this is exceeded by the luxuriance of the marshy meadows of the Bridgwater Level, which are, however, liable to be flooded, and are maintained against the sea at considerable expense. The orchards of Somerset are second only to those of Devon in area and importance, and cider is largely made; while Cheddar cheese has a national reputation. Manufactures maintain considerable importance, particularly in textiles (chiefly woollens), potteries, paper-making, and gloving; and though the city lies mainly on the Gloucestershire side of the Avon, and is a county to itself, Somerset may fairly claim a share also in the commercial importance of Bristol (q.v.).

The bone-caves of the Mendips have supplied evidence of the presence in Somerset of neolithic as well as palæolithic man; and there is abundant evidence of the occupation by strong and comparatively civilised tribes prior to the Roman invasion in the remains of important hill fortresses (Hamdon, Castle Neroche, Dolbury, Maesbury, Worlebury, Cadbury), while the megalithic circles and other remains at Stanton Drew are among the most interesting in the kingdom. Immediately prior to the Roman invasion under Claudius the north of the county was inhabited by the Belgæ, while the territory of the Dumnonii seems to have extended over the Devon border to the marshy and central district, which probably formed a strong natural frontier, though there is evidence that part of this area had been embanked against the sea in pre-Roman times. The Mendips must, however, have formed part of the earliest Roman conquest, as pigs of lead have been found there bearing the names of Claudius, Britannicus, and Vespasian. Somerset became one of the chief seats of Roman civilisation in Britain. Bath (q.v.), as the city of *Aquæ Sulis*, was a centre of refinement and luxury. The remains of the baths built by the Romans for the reception of the famous mineral waters are among the most important relics of the Roman period in England. But the impress of the Roman has been left in nearly every part of the county—in villas, roads, pottery kilns, interments, and coins; while Ilchester, like Bath, was a Roman city. Tradition claims for Glastonbury (q.v.) the honour of being the first seat of Christianity in Britain. Under the Saxons the district became known as the home of the Sumersetan, and took its present name, the origin of which is disputed. Part first came under Saxon sway in 658, but its inclusion in Wessex was not complete until 710, when Gerente was defeated by Ine, who made Taunton (q.v.) his chief fortress, and founded the cathedral of Wells (q.v.), which became the seat

of the bishopric of the Somersætas (since Bath and Wells) in 909. Somerset was the last home of Saxon freedom when Alfred took refuge at Athelney, defended by trackless marshes. It was at Wedmore that Alfred made his treaty with Guthrum, though the claims of Edington to be the Æthandune where he won his most memorable victory are doubtful. In the wars of the Roses Somerset was in the main Lancastrian; in the wars of the Commonwealth it was chiefly parliamentarian, and the stout defence of Taunton first made famous the name of Admiral Blake. The county was also the centre of Monmouth's operations; and it was chiefly Somersetshire men who fell at Sedgemoor (1685). The county has two cities—Bath and Wells; a parliamentary borough in Bath (Taunton also till 1918); an important manufacturing port in Bridgwater; one of the finest watering-places on the western coast in Weston-super-Mare; manufacturing towns in Frome, Yeovil, Shepton Mallet, and Wellington; and six county parliamentary divisions.

Somers' Islands. See BERMUDAS.

Somerville, a city of Massachusetts, a suburb of Boston, 2 miles from the central station. It has many handsome residences, contains tube-works, bleaching-works, and large slaughter-houses, and manufactures also flour, leather, iron, oil, bricks, &c. Pop. 93,000.

Somerville, MRS MARY, a lady famed for her mastery of mathematics and physical science, was the daughter of Admiral Sir William Fairfax, and was born on 26th December 1780 at Jedburgh in the manse of her uncle and future father-in-law, Thomas Somerville, D.D. (1741–1830), the author of *My own Life and Times*. She was brought up at Burntisland and Edinburgh, amid somewhat narrow family circumstances. It was in an algebraic sum in a magazine of fashions that she first made acquaintance with the subject that most engrossed her attention in after-life. In 1804 she married a cousin, Captain Greig, of the Russian navy, Russian consul in London. He died in 1806, and it was not till her return north as a widow that she was free to buy the books she wanted, and to study the subject that most interested her. In 1812 she married another cousin, Dr William Somerville, inspector of the army medical board, who entered warmly into all her ideas. They removed to London in 1816, where Mrs Somerville went much into society, and became known as possessor of scientific interests and gifts. In 1823 she was invited by Lord Brougham to try to popularise for the English public Laplace's great work, the *Mécanique Céleste*; and the *Celestial Mechanism of the Heavens* (1830) was received with the greatest admiration. Mrs Somerville was awarded a royal pension of £300 in 1835. Other works by her were *The Connection of the Physical Sciences* (1835), *Physical Geography* (1848), and *Molecular and Microscopic Science* (1866). Mrs Somerville, who for many years resided in Italy, died at Naples, 29th November 1872. An autobiography, edited and supplemented by her daughter, was published in 1873. After her is named Somerville College for women at Oxford (1894; founded as Somerville Hall 1879).

Somme, a river of northern France, rises not far from St Quentin in the dept. of Aisne, flows in a south-west, then north-west direction, and after a course of 150 miles falls into the English Channel not far from St Valery. It is navigable for vessels of 300 tons up to Abbeville (q.v.), and its upper course is canalised. See WAR (GREAT).—The *département* of Somme, in the north of France, formerly part of the province of Picardy, touches the English Channel on the north-west. Area, 2443 sq. m. The dept. is level, very fertile, and amongst the best cultivated districts of France. Much cider is made and poultry reared. The textile industries (wool, cotton, linen, hemp, silk spinning, and the weaving of mixed stuffs, cloth, velvet, carpets) give the principal mechanical employments; but there are also large iron-foundries, lock, soap, candle, chemical, paper, and beet-root sugar factories, distilleries, and breweries. There are the five arrondissements of Abbeville, Amiens, Doullens, Montdidier, and Péronne; chief town, Amiens. Pop. (1872) 557,015; (1921) 452,624.

Somnambulism (Lat. *somnus*, 'sleep,' *ambulo*, 'I walk') is a disorder of sleep. It is symptomatic of more or less activity in some of the psychical and motor areas of the brain, while the centres that preside over consciousness are slumbering soundly. There are different forms, as sleep-crying, sleep-talking (*somniloquy*), and sleep-walking. These all involve sensori-motor acts.

Sleep-walking is closely related to hysteria, and it occasionally alternates with this and allied diseases. It occurs mostly in youth, affecting males and females in almost equal proportion; commonly, although not invariably, it disappears when adult age is attained. It is met with chiefly in persons of nervous temperament, and in those who have an inherited proclivity to neurotic disease. The exciting causes embrace mental excitement, overwork, fright, bodily fatigue, hepatic and digestive disorders, worms, and an overloaded bladder, and in females uterine and ovarian troubles. Sleep-walking is one of the neuroses of deep sleep. It occasionally presages graver maladies; generally these may be prevented by suitable treatment. It is important to recognise that it is a pathological state, and that no one who is in perfect health walks in his sleep. Sleep-walking is an acted dream, which generally supervenes when sleep is deepest—often during the first deep sleep. The dreamer usually stages it so precisely that he is able to act it with admirable exactness. In the first visitation the dream may be simple, and merely impel the sleeper to rise from bed to walk round the room and then return to bed. Eventually the dreams become more elaborate, and may embrace many complex operations, in which the individual has to elude articles of furniture, unlock doors, open windows, walk along dangerous roofs, or beside the edge of precipices—in short, perform feats he could not possibly execute in his waking moments. Sleep-walkers have achieved the most diverse exploits without awaking. They have swum across rivers, thrashed corn, ridden on horseback, and even transacted their usual daily work. They are oblivious to danger, and untrammelled by fear; this, combined with an exaltation of muscular sense, enables them to effect their movements precisely and quickly. Their feats, however, are sub-conscious, and not, as is popularly supposed, superhuman. Their senses, which are not connected with the dream, slumber; they do not see, hear, or smell, so they perform with their eyes shut as well as open, and they may be shaken, and may themselves cough and sneeze without being awakened. A certain degree of anaesthesia appears to render them insensitive to

pain. After the dream-act is ended the sleeper returns to bed, to sleep until the usual hour for rising, and when he awakes he either does not recollect anything about his escapade, or remembers it only as a dream. Most frequently he recollects it in a subsequent sleep-walk, just as some dreams are only remembered in recurring dreams. Sleep-walking leads the actor into situations which endanger life, and deaths are frequently recorded from fatalities arising thus. If the sleep-walker be awakened at a critical moment, coolness and precision are replaced by agitation and fright, movements become halting and clumsy, and accident usually follows. Many tragedies have been enacted in this state, and these are of great forensic interest. From every point of view sleep-walking is a source of much anxiety to the afflicted and his relatives.

A sleep-walker found in his wanderings ought not to be awakened, but led back to bed as gently as possible. Abrupt awakening may give rise to shock, and may mark the onset of grave nervous disorders. Whilst it is always advisable to seek medical advice, it may be indicated that the general health should be attended to, so that it may be improved; and all exciting causes should be remedied or avoided, as, for example, all undue excitement and fatigue of mind and body. The sleeping conditions require consideration; in some cases it is advisable that some one should sleep in the same room. Occasionally, it is advantageous to awaken the sleeper at the end of the first hour of sleep, when it is deepest, to prevent it becoming too profound. Hypnotism is sometimes called artificial somnambulism. See the works and articles cited at SLEEP.

Somnath (Pattan), an ancient town of Gujarat, in India, is situated on the south-west coast of the peninsula of Kathiawar, with a population of 8427 (1921), mostly Mohammedans. The town is defended by a strong fort and by a trench cut in the solid rock. It contains many ruins and memorials of Krishna, who died and was buried close by. Not far from the town stand the ruins of the celebrated Hindu temple of Somnath. Its great sanctity and the fame of its enormous wealth attracted the imagination and avarice of the sultan Mahmud of Ghazni (1024). He took the temple after a desperate defence by its guardians, destroyed the sacred image, and carried off its stores of jewels and (according to the tradition) the wonderful temple gates. It is, however, more than doubtful whether the 'gates of Somnath' which Lord Ellenborough brought back from Afghanistan in 1842, and purposed to have restored to Somnath after having carried them in solemn procession through great part of Northern India, really are the gates of the ancient temple beside the Arabian Sea in Kathiawar. The gates that were brought from Afghanistan, and eventually placed in the arsenal of Agra, are made of cedar and richly carved, and measure 11 feet in height by 9 feet 6 inches in width.

Sonata, a musical composition usually of three or four movements, designed chiefly for a solo instrument. Before the 17th century the overwhelming tendency of musical development had been to increase by every possible device the vocal resources of the art, a culminating point being reached in the works of Palestrina and the school of madrigal writers. Instrumental music had been represented for the most part by dance tunes which had no great formal development, whilst the early attempts at opera relied almost entirely on the vocal element for their effect. In fact, abstract music, independent of external impressions, and deriving all its interest from intrinsic qualities, was up to this time unknown. Some very early sonatas,

published at Venice in 1624, consisted of a single movement; but the principle of a succession of contrasted movements, as in the case of the suite, was eventually established, all existing musical forms being pressed into service to secure its fulfilment. Thus, the 'first movement' consisted of a kind of canzona, imitated from a choral form kindred to the madrigal; the declamatory recitative of the opera was the source of the 'second movement'; and the remaining portions of the sonata were founded on dance-rhythms. Its progress tended towards emancipation from originating influences, whereas the suite adhered closely to dance forms. To secure for each movement structural balance and diversity of material additional 'subjects' were introduced, and the several portions were divided into 'sections,' balanced and contrasted both as to melody and key; whilst, as to time, the alternation of quick and slow movements became a recognised principle. Corelli and other writers of his school wrote sonatas chiefly for the violin, the genius of Handel and Bach being also employed in the same field. The improvements effected in the construction of the harpsichord and clavichord at length obtained for them a due measure of attention from Domenico Scarlatti and C. P. Emanuel Bach, whose complete mastery of these instruments enabled them to write clavier-sonatas with the happiest effect. The subsequent efforts of Haydn and Mozart brought the form of the sonata to great perfection of elegance and symmetry, a result to which Clementi and Dussek also contributed. But the acme of development was reached by Beethoven, who infused into the somewhat mechanical forms of his predecessors the spirit of human emotion. Under him the different parts of the sonata, instead of being mere adjacent sections, became items of one complete organic whole. The progression of his thoughts constituted a work of art, a poem in sound, in which, while the idea was paramount, the form was more or less veiled, the perfection of the whole resulting from a true and just balance between the two. Weber and Schubert continued to employ the old model, but with them its rules and restraints gradually gave way before the growing importance of the idea. At a later period Schumann attempted a compromise by means of ingenious devices, and Brahms in two early pianoforte-sonatas had worked along similar lines; while notable composers of the present day are still trying to extend the limits of sonata-form in conformity with modern tendencies. See the article by Sir C. Hubert H. Parry in Grove's *Dictionary of Music*.

Sonderbund, a union of the Catholic cantons of Switzerland (q.v.), which led to civil war in 1845.

Sonderburg. See ALSEN.

Sondershausen, a town of Thuringia, formerly capital of Schwarzburg-Sondershausen (q.v.), pleasantly situated on the Wipper, 34 miles by rail N. of Erfurt. It has a large castle. Pop. 10,000.

Sondrio, an Italian town, capital of a province, on the Adda, 25 miles E. of the Lake of Como. It is the capital of the Valtellina, which produces much red wine. Pop. (1921) 9572. Sixteen miles E. by rail is Tirano, from which diverge the roads to the Bernina (q.v.) and the Stelvio Pass (q.v.). The former route is now followed by a railway, which at Samaden, in the Upper Engadine, connects with the Rhetian railway from Chur (Coire).

Song, a short poem, adapted for singing, or set to music. A song generally turns on some single thought or feeling simply expressed in a number of stanzas or strophes (see LYRIC, BALLAD, POETRY, and the articles on the great song-writers). The music to which it is allied should serve to add force and clearness to its meaning with or without

the assistance of an instrumental accompaniment. The vast stores of simple ballads, of which various nations in time became possessed, are known as 'folk-songs' (*volkslieder*), as being the unstudied outcome of their popular tastes, feelings, and aspirations. In the modern 'art-song' (*kunstlied*) the cultivated instincts of the musician are brought to bear upon the utterances of the poet. The range of this class of song is extremely wide, and includes examples resembling the folk-song in simplicity, as well as those of a more ambitious character, which for adequate interpretation often depend very largely on the accompaniment, the voice part sometimes consisting of little more than declamation of words whose meaning is further conveyed by instrumental devices. Between these two extremes every variety and combination of treatment is displayed, some songs being strophic in form, the same melody serving for each stanza, whilst others are 'composed throughout,' both melody and accompaniment changing in sympathy with the narrative and sentiments expressed by the words. The pinnacle of perfection in song-writing has been reached by German composers, and pre-eminently by Schubert, Schumann, Brahms, and Loewe. Among celebrated English composers of song music may be named Henry Laves, who very early excelled in the art of setting words with due regard for accent and emphasis; Henry Purcell, the greatest among English song-writers; with Carey, Arne, and Boyce. To these must be added Dibdin, famous for his 'Tom Bowling'; Davy, whose memory is kept green by his 'Bay of Biscay'; John Brahan, who wrote the 'Death of Nelson'; and Charles Horn, composer of 'Cherry Ripe.' Sir Henry Bishop also enjoyed a lengthened popularity. The growth of national taste in respect of song has not kept pace with its advance in other branches of music, many excellent writers belonging to the later part of the 19th century being as yet for the most part unappreciated, while publishers find a large sale for rapid compositions in the so-called 'drawing-room' style. Songs written for several voices are known as part-songs, glees, madrigals, &c. See CATCH, GLEE, MADRIGAL, ROUND; and the article 'Song' in Grove's *Dictionary of Music*. For the song of birds, see BIRD; and for the Song of Songs, or Song of Solomon, see CANTICLES.

Songhay, or SONRHAI, a former kingdom of Africa, extended on both sides of the Niger below its great bend. In the 15th century the empire extended from Lake Tsad almost to the Atlantic, but early in the 17th century it was overthrown by the sultan of Morocco.

Song-ka, the chief river of Tong-king (q.v.).

Sonnblick, a height 10,277 feet high amongst the Salzburg Mountains, on whose summit is a meteorological observatory, with a shelter built in 1886 by the Austrian and German Alpine Clubs.

Sonnet (Ital. *sonetto*, dim. of *suono*; Fr. *sonnet*). In poetic art the sonnet—a stanza mostly iambic in movement, properly decasyllabic or hendecasyllabic in metre, always in fourteen lines arranged properly according to some law that is recognised at once as having universal acceptance—belongs entirely to the rhymed poetry of the modern world. Sonnets are divided into regular and irregular. All regular sonnets are divisible into: (1) The sonnet of simple stanza in which the staves follow each other in three quatrains of alternate rhymes clinched at last by a couplet. This form is for obvious reasons called the Shakespearian sonnet. (2) The sonnet of compound stanza divided generally, but not always, both as regards sense-rhythm and metre-rhythm, into two parts—an octave consisting of eight lines (the first line of which rhymes with the fourth, the fifth, and the

eighth lines, the second line with the third, the sixth, and the seventh), and a sestet consisting of six lines running on two or else three rhymes in an arrangement which, though free from prescription, must always act as a response by way of either ebb or flow to the metrical billow embodied in the octave. This form is for equally obvious reasons called Petrarchan. Within the space at our command it is impossible even to glance at the history of the sonnet here, save as it now and then discloses itself in our remarks upon the general principles governing the sonnet's matter and its form.

Though poetic art has many functions and many methods, the two following among its functions seem specially to concern us in treating of the sonnet: The function of giving spontaneous voice to the emotions and passions of the poet's soul; and the function of poetising didactic matter and bringing it into poetic art. With regard to the first of these functions, although the sonnet is a good medium for expressing passion and emotion, it cannot be said to take precedence in this respect of other and less inherently monumental forms. The ode of Sappho, the bird-like song of Catullus, and the free-moving rhymed lyric of modern times are probably better adapted to give expression to simple passion at white heat—while on the other hand they are certainly better adapted to give voice to that less intense form of passion which can pause to deck itself with the flowers of a beautiful fancy—than is the sonnet—even the sonnet of simple stanza of Shakespeare and Drayton. With regard, however, to the second of the above-mentioned functions of the poet—that of poetising didactic matter—a function which of course can only be exercised by passing the didactic matter through a laboratory as creative and as recreative as nature's own, the laboratory of a true poet's imagination, the pure lyric must of course yield to the sonnet. Indeed, it is an open question whether since the Romantic revival the sonnet has not been gradually taking precedence of most other forms as an embodiment of poetised didactics. And should this on inquiry be found to be the case, the importance of this form will be made manifest. For as the mind of man widens in mere knowledge and intelligence fresh prose material is being furnished for the poetic laboratory every day. And the question, What is the poetic form best suited to embody and secure this ever-increasing and ever-varying wealth?—a question which has to be answered by each literature, and indeed by each period of each literature, for itself—goes to the root of poetic criticism. Of course, before didactic matter can become anything more than versified prose, it has to be excarnated from the prose tissue in which all such matter takes birth, and then incarnated anew in the spiritualised tissue of which the poetic body is and must always be composed. Hence it is not enough for the poet to use the sieve, 'as Dante would say,' in selecting 'noble words.' The best prose writers from Plato downwards have been in the habit of doing this. When Waller said:

Things of deep sense we may in prose unfold,
But they move more in lofty numbers told,

he meant by 'lofty numbers' those semi-poetic 'numbers' of the English couplet in which poetised didactics were in his time embodied—as in the time of Shakespeare such poetised secretions of the mere *intellectus cogitabundus* were put into the mouths of dramatic characters after the approved old fashion of the classical dramatists.

Since the Romantic revival, however, poetic art has undergone an entire change. Acted drama cannot now receive poetised didactics, which would in these days slacken the movement and disturb the illusion required, while as to the kind of epigram-in-solution or half-poetised quintessential

prose which is embodied in the 18th-century couplet the criticism of the Romantic revival is apt to consider this not so much as poetry as an intermediate form—and an extremely rich and precious one—between poetry and prose. Epigrammatic matter must, to exist at all, be knowing, and as knowingness and romanticism are mutually destructive, it is evident that some form other than the couplet, which is so associated with epigram, must in our time be used for the poetising of didactic matter of the unworldly and lofty kind. And the sonnet of octave and sestet is a form less epigrammatic than any other—a form moreover which can never, as certain other stanzaic forms can do, embody mere quintessential prose without proclaiming its poverty, but must always be poetic in its very texture—a form indeed which will not bear one line that is not either in essence or in method poetic or else 'rhetorical' in Dante's sense when he defined poetry to be 'a rhetorical composition set to music.' So absolutely poetic a form is this that if it should happen that the diction will not on account of the subject bear elevation, it has to be at once poetised by one of those skilful disturbances of the prose order of the words of which Wordsworth was so great a master.

The fact of the word sonnet being connected with *sonare*, to play upon an instrument, shows that a knowledge of music, though perhaps not essential, is of great value to a sonnet-writer. Indeed, owing to the consonantal character of our language a knowledge of music is really of more importance to the English than to the Italian sonnet-writer. Although the 'singing words' essential to a good song for music need not perhaps be greatly sought in the sonnet (save in the special and somewhat rare form mentioned further on), still vowel-composition and that attention to sibilants which Pindar is constantly showing in his odes—that attention which Dionysius of Halicarnassus extolled—and also the softening of consonantal feet by liquids are extremely important in the sonnet even although it is no longer written to be set to music. After much practice in the art of rhymed poetry—when every feasible rhyme leaps into the brain of the poet the moment that a line-ending has suggested itself to his mind—this attention to structural demands becomes instinctive, and is exercised in that half-unconscious and rapid evolution of the mental processes which the witty conversationalist shows in repartee, and which the pianist exhibits when touching the keyboard—supposing of course that the poet is a born rhymner. It is, however, a curious and interesting fact that ever since the time of Piers Plowman (when alliterative measures gave way to rhymed measures) English poets have been clearly divisible into two classes—those to whom rhyme is an aid and those to whom rhyme is more or less a check. And still more curious and interesting is it, that while three of the greatest poets, Shakespeare, Marlowe, and Milton, belong to the one class, Coleridge (who by endowment perhaps stands next to them) belongs to the other. This is why some of the strongest English poets have not been successful in the sonnet, where the rhyme-demands are very great. For some reason or another the rhythmic impulse within them has not been stimulated but crippled and tortured by the spur of rhyme.

With regard to prescription in the number of the lines and the arrangement of the rhymes of the sonnet, metrical art offers the reader two opposite kinds of pleasure; the pleasure derived from a sense of prescribed form, as in the sonnet, the ballade, the *rispetto*, the *stornello*, &c., and the pleasure derived from a sense of freedom from prescribed form as afforded by those pure lyrics, in which the form is, or at least should be, governed by the emotion.

Now every poetical composition should show at once which of these kinds of pleasure is being offered to the reader and should also satisfy the expectation raised, for he will experience a sense of disappointment on being proffered one kind of poetic pleasure when he has been led, by the stanzaic arrangement or otherwise, to expect another. Nevertheless a certain few of our great sonnets are irregular, for a great poet can do anything.

With inference to regular sonnets it is self-evident, as regards the sonnet of compound stanza, that there are four different forms into which may fall a metrical structure consisting of an octave of a prescriptive arrangement of rhymes and a sestet consisting of another set of rhymes that are free in arrangement from prescription. And some years ago the present writer exemplified these in 'four sonnets on the sonnet,' one only of which, under the name of 'The Sonnet's Voice,' originally printed in the *Athenaeum*, was widely circulated in sonnet-anthologies. These varieties of the sonnet of octave and sestet are: (1) The sonnet in which the stronger portion both in rhythm and in substance is embodied in the sestet. (2) The sonnet in which the stronger portion both in rhythm and in substance is embodied in the octave. (3) The sonnet in which the sestet is not separated from the octave, but seems to be merely a portion of the octave's movement rising to a close more or less climacteric. (4) The sonnet in which the sestet seems to be added to the octave's movement, added after its apparent termination in a kind of tailpiece, answering to what in music we call the 'coda.'

With regard to the second of these varieties—the one exemplified in 'The Sonnet's Voice'—perhaps the ideal form has the octave in double rhymes and the sestet in single rhymes. But it has to be remembered by the poet that between the effect of Italian rhymes and the effect of English double rhymes there is a great difference. Save in the hands of a sonnet-writer of great practice in the art of vowel-composition, in the art of using singing words, and in the art of softening our consonantal language, by the proper use of liquids and subtle and concealed alliterations, the English rhyme-beat in the double-rhyme octave of this variety is apt to become too heavy for the single-rhyme rhyme-beat in the sestet. By attention to these requirements, however, the rhyme-beat may be so lightened that this variety may become the most brilliant of all.

With regard to the sonnet of simple stanza, it has two special glories: it was the form adopted by Shakespeare, and in it is written Drayton's famous love-sonnet. Hartley Coleridge wrote some fine sonnets in this form; so did Keats: but on the whole it has been neglected in recent times.

Sonora, a frontier state in the north-west of Mexico, on the Gulf of California. It is the second largest in the republic. Area, 76,900 sq. m.; pop. 270,000. The coast is flat and sandy, the interior filled with wooded mountains and fertile valleys. Malaria is mostly confined to one part of the coast. Here the climate is hot, but in the mountains there is frost for five months in the year. The chief rivers are the Sonora, Yaqui, and Mayo. The principal wealth of the state is in its minerals, especially gold, silver, mercury, and iron. Agriculture, wine-growing, and cattle-rearing are also successful, and cottons, hats, shoes, and soaps are manufactured. Capital, Hermosillo; chief port, Guaymas.

Sonsonate, a town of Salvador, on the Río Grande, 15 miles by rail N. of Acapulco. It was founded by Alvarado in 1524. Pop. 16,000.

Sontag, HENRIETTA, COUNTESS ROSSI, a German singer, was born at Coblenz on 3d January 1806, and was educated by her parents to their own profession of the stage. She learned singing at Prague, and made her début there when only fifteen. After a brilliant operatic career at Vienna, Berlin, and Paris, she married Count Rossi in 1828, and shortly afterwards left the stage. Compelled by money difficulties to reappear in 1849, she met with renewed success both in Europe and in America, but died in Mexico on 17th June 1854.

Sonthals. See SANTALS.

Soochoo, or SUCHAU, previous to the Taiping rebellion one of the largest cities in China, is situated on the Grand Canal, 50 miles WNW. of Shanghai, in the province of Kiang-su. It stands on numerous islands separated by canals, and since 1896 has been accessible as a treaty-port. The city walls have a circuit of 10 miles. Soochoo has for generations been a noted centre of the silk manufacture and of the printing of cheap Chinese classics. It was captured by the Taipings, but recovered by 'Chinese' Gordon in 1863, on which occasion the city with its many handsome buildings was almost wholly destroyed. Pop. 500,000.

Sooloo Islands. See SULU ISLANDS.

Soot. The soot both of wood and of coal is serviceable as Manure (q.v.) on account of the sulphate of ammonia it contains, especially for young cereals, for grasses, and for carrots. See SMOKE.

Sophia. See SOFIA.

Sophia, Electress of Hanover, born on 13th October 1630, was the youngest of the thirteen children of Elizabeth (q.v.), queen of Bohemia. In 1658 she married Ernest Augustus, Duke of Brunswick-Lüneburg, and afterwards Elector of Hanover, and by him she was the mother of George I. She died 8th June 1714. See A. W. Ward's *Electress Sophia and the Hanoverian Succession* (1903). For Sophia Dorothea, the wife of George I., see KONIGSMARK.

Sophia, St (Greek *Hagia Sophia*, 'Holy Wisdom'—i.e. the eternal wisdom of God or the Logos, and not a human saint), to whom Greek churches were often dedicated; especially the great church of Constantinople (q.v.), erected by Justinian in 538–568 A.D. Its dimensions and a sectional plan are given at BYZANTINE ARCHITECTURE.

Sophists. The Greek word *sophistēs* (from *sophos* = 'skilled,' 'wise') meant originally any one of acknowledged or professed skill; thus, the term was applied to the seven sages (whether philosophers, like Thales, or statesmen, like Solon), to poets, musicians, &c. In the 5th and 4th centuries B.C. it came to be applied specially to those who made a profession of teaching all or any of the higher branches of learning. The great intellectual awakening of Athens after the Persian war, and the growth of democracy in Sicily and elsewhere, as well as at Athens, which gave skill in public speaking a new importance, led to the demand for an education which should go beyond the old training in 'gymnastic' and 'music' (i.e. reading, writing, singing, and reciting from the poets). To meet this demand there arose a class of professional teachers, wandering scholars, who undertook to provide what we should call 'higher education.' This new movement presents certain resemblances to the rise of the universities in the 13th century, to the popularising of learning and science in the 18th and 19th centuries, to the 'University Extension' movement of to-day. Some of these 'Sophists' were more specially teachers of rhetoric—i.e. they gave particular attention to the *form* of public speaking, and as

such they are the beginners of Greek prose style. Originally *artistic* expression takes the form of verse. The poet is the 'maker,' the artist in language: prose is simply 'ordinary speech.' But from the time of the rhetoricians, such as Gorgias (q.v.) of Leontini, prose also becomes an art. The first effect of the deliberate pursuit of artistic form in prose was to produce a pedantic and artificial style. (We can trace the evil influence of Gorgias in the 'speeches' in Thucydides.) But this attention to language was the preparatory training for the simple beauty of the best Attic prose. Other Sophists gave more attention to the *matter* of public speech—the questions of right and wrong which come before law-courts and political assemblies—and in this way they were the beginners of moral and political philosophy. The earlier Greek philosophers, with the partial exception of the Pythagoreans, had hardly treated of human matters: they had been ontologists and cosmologists. Protagoras (q.v.) of Abdera and Prodicus of Ceos may be taken as famous and favourable examples of the professors of 'virtue.' It must be remembered that the teacher of conduct and the moral philosopher were not distinguished even by Plato and Aristotle. Other Sophists, like Hippias of Elis, professed to teach universal knowledge—what we call 'general culture.' Others again, like Euthydemus and Dionysiodorus (who appear in Plato's dialogue named after the first of them), devoted themselves specially to the art of disputation, and thus prepared the way for the science of logic.

The ambitious youth of Athens flocked to a fashionable Sophist from intellectual interest in the new learning and in order to acquire an education which would fit them to obtain success in the law-courts and in the popular assembly, or to acquit themselves with distinction in a discussion on any subject whatever. The various Sophists naturally differed much from each other in ability, in character, and in the degree of seriousness with which they regarded their function as teachers; and some may very well have deserved the censure expressed in Aristotle's definition of the Sophist as 'a man who makes money by sham wisdom' (in *Soph. Elench.* i). In the eyes of old-fashioned persons the whole class was regarded with suspicion: the skill of the clever orator or disputant seemed to have something immoral about it, because it might enable the worse cause to appear the better. And to discuss the nature of right and wrong, or to theorise about the foundations of society, was then, as in other ages, regarded as dangerous. In the eyes of such persons Socrates and Plato were 'Sophists' just as much as the rest, although Socrates and Plato, conscious of their own intellectual honesty and earnestness, and not teaching for 'pay,' disowned the title. When the various branches of the new learning came to be differentiated, we find the rhetorician Isocrates (q.v.), to whom the term would certainly be applied by the average Athenian and by Plato, applying the term to Plato, but not to himself. Again, whereas Plato applies it to Protagoras, Gorgias, Hippias, &c., we find that Aristotle in a passage (*Eth. Nic.* ix. 1) where he speaks disparagingly of the Sophists contrasts Protagoras with them. The word had come to acquire an evil connotation, such as survives in our use of the term 'sophistry.' But it is quite a delusion, as was conclusively shown by Grote (*History of Greece*, pt. ii. chap. 67), to suppose that the Sophists were a *sect* of philosophers, with pernicious principles, who systematically undermined the morality of the Hellenic world. They were not a sect, but a profession: and on the whole they were neither better nor worse than their age. Like the journalist or

litterateur of our own time, they succeeded by supplying what the public wanted. The Platonic Socrates, their adversary, himself says, 'Our youth are corrupted, not by the individual Sophists, but by the public, which is the great Sophist, against whose influence any private teacher wages an unequal contest' (*Republic*, vi. 492).

There is no common 'Sophistic' doctrine. Different Sophists were influenced by different schools of philosophy. They were the popularisers of older doctrines. Thus, Protagoras was influenced by Heraclitus (q.v.), whose doctrine of universal flux gives a basis for Protagoras' assertion of the absolute relativity of knowledge ('man is the measure of all things; nothing is true but the sensation of the moment'). The alleged influence of his fellow-townsmen, Democritus (q.v.), seems less likely; for Democritus was about twenty years younger. Still the Atomist resolution of all things into mere *arrangements* of the only *real* existences (the atoms and the void) very likely helped to supply a basis for the distinction between 'convention' and 'nature,' which was much used by some Sophists and became a commonplace of the period. Gorgias is said to have been a disciple of Empedocles (q.v.), and was certainly influenced by the Eleatics (q.v.). His paradoxical treatise on 'Nature or the non-existent' is clearly a sceptical working out of the Eleatic principle of the unality of the manifold. We have no sufficient knowledge to justify the attempts made by some German scholars to classify the Sophists according to different philosophical schools; and it is, moreover, unlikely that *popular* philosophers should admit of any very precise affiliation. We can only group them in a very rough way, such as has been attempted above. Some historians of philosophy (e.g. Zeller and Ueberweg) lay stress on the distinction between the earlier and later Sophists, considering the 'later Sophists' (such as Polus of Agrigentum, a pupil of Gorgias, Thrasyarchus of Chalcidion, Euthydemus, &c.) to represent a distinct degeneracy in the class. This, however, seems doubtful, except in the sense that, as time went on, 'rhetoricians' and 'philosophers' came to be more clearly differentiated from among the mass of the profession; and the *name* Sophist degenerated as we have seen. Professor Sidgwick argued that the 'Eristic' or disputatious Sophists were really a degenerate offshoot of the Socratic school; but against this hypothesis there are many objections.

While Grote is perfectly correct in holding that the Sophists are not a sect and have no common doctrine, he errs in ignoring the fact that they represent a common tendency, the new spirit of the age. The awakening of reflection on political and social institutions, on morals and religion, and the wider diffusion of enlightenment produced in Hellas the same spirit of 'freethinking,' individualism, and sceptical criticism which we find among the 'Humanists' of the Renaissance, and still more among the English 'Deists' and French 'Encyclopedists' of the 18th century. Of this intellectual movement the Sophists were at once the outcome and the leaders. The differences between the Sophists might be paralleled by the differences between Voltaire, Diderot, Rousseau, &c., and yet all these writers share a common tendency. The very opinions maintained by certain Sophists reappear in more fully developed forms among English and French writers of the 17th and 18th centuries. Thus, Thrasyarchus, in Plato's *Republic*, bases right simply on the command of the stronger, by which he means the sovereign power in the state—the theory of Hobbes, developed afterwards in its legal aspects by Bentham and Austin. From the second book of Plato's

Republic it appears that the Social Contract theory had already been propounded, almost certainly by some Sophist. Aristotle (*Politics*, iii. 9) quotes Lycophron the Sophist as holding that government was only concerned with the protection of individual rights. Alcidas, the rhetorician, maintained that 'God made all men free; Nature has made none a slave.' This and similar sentiments, which we may call 'Sophistic,' in the sense that they belong to the new Rationalism, are to be found frequently expressed in the extant plays and fragments of Euripides. Even Herodotus, though his style is unaffected by the rhetorical schools, has also imbibed a certain tolerant scepticism, which appears in his treatment of the diversity of customs and religious beliefs; and the debate about the best form of government (iii. 80-82), which he unhistorically puts into the mouth of Persians, is probably due to a 'Sophistic' source, and may indeed be called the earliest piece of Greek political philosophy that has come down to us. Much of the teaching of the Sophists was undoubtedly destructive of the old fabric of Greek belief and of Greek society, which rested on the narrow basis of an exclusive citizen caste with a substructure of slavery. The modern student will not necessarily think the worse of the Sophists on that account; though the majority of them were probably by no means conscious of the significance of the critical weapons they handled. By raising problems in almost every department of thought, for which they could find no satisfactory answers, they prepared the way for the great period of Athenian philosophy (see *SOCRATES*). Later the term 'Sophist' came into reputation again; some Greek professors of rhetoric under the Roman empire were described as Sophists on their tombs.

The significance of the Sophists in the development of Greek thought was first put in a true light by Hegel in his *History of Philosophy*. Besides the histories of Greek philosophy (see *PHILOSOPHY*, *PLATO*) and Grote, see two articles by Sidgwick, defending Grote's view, in the *Journal of Philosophy*, vols. iv. and v.; Bann's *Greek Philosophers* (1883); Mahaffy's books on Greek thought before and after the Roman Conquest (1887-96); Walden's *Universities of Ancient Greece* (1912).

Sophocles, the Athenian tragic poet, was born c. 496 B.C., and died c. 405 at the age of ninety-one. His father's name was Sophillus, and his native district was Colonus, a suburban quarter on the banks of the Cephissus, much frequented by the knights and wealthy citizens of Athens. He partook in full measure of the highest education of his time, and was especially distinguished in music, which he learned from Lamprocles. At sixteen he was chosen to lead the chorus of youths who celebrated the naval victory of Salamis (480). At the age of twenty-eight he came to the front by entering into competition with Æschylus, his elder by thirty years, whose pre-eminence as a tragic poet had long been undisputed. The judges on this occasion, according to an oft-repeated tradition, were Cimon and his fellow-generals, just returned from Scyros. The younger poet was preferred; and his triumph had a decisive influence on the future of the tragic art. For not only are the mature works of Sophocles and those of Euripides, his younger brother in poetry, the fulfilment of the promise then given, but the Orestean trilogy of Æschylus, in which Greek tragedy attained its highest limit, was brought out ten years after this, and bears unmistakable proofs of the impression which the art of Sophocles had made upon his elder and greater rival. Sophocles never forsook Athens as both Æschylus and Euripides did, but he was repeatedly employed on embassies to other Grecian states, and in the Samian war of 440 he was appointed general in a

joint command with Pericles. This choice is said to have been due to the success of the *Antigone*, one of the earliest of the poet's seven extant plays, as the *Œdipus Coloneus* and *Philoctetes* are certainly the latest. The probable order is *Ajax*, *Antigone*, *Electra*, *Œdipus Tyrannus*, *Trachiniae*, *Œdipus Coloneus*, *Philoctetes*. Less than a tithe of the work of Sophocles remains to us; but of the seven plays each one has superlative excellences, and stands prominently forth amongst the master-works of the human spirit. The characteristics of Sophocles are a dramatic structure all but faultless, the combination of wonderful subtlety with intense fire, and of a noble ideal with truth and naturalness. His subjects were necessarily drawn from Hellenic legend. His motives in selecting them were mainly artistic, but to some extent also religious or patriotic. In his treatment of them he never loses sight of the main principles of tragic art. His method turns largely on pathetic contrasts (1) of situation, (2) of character.

(1) The change of fortune which forms the crisis of each play is often rendered more impressive through the profound unconsciousness, at the beginning of the action, of the persons who are to be affected by it. The case of *Œdipus* is the capital illustration of this remark; but it applies also to Creon in the *Antigone*, to Electra, Deianira, Philoctetes, and to the chorus in the *Ajax* and *Œdipus Coloneus*. Sometimes the chief agent, *Antigone* for example, is fully conscious of the real position of things, but in every case appearance and reality are strongly opposed.

(2) The persons in Sophocles are most skilfully adapted to the main situation and action of each play. The addition of a third actor to the two that had formerly sufficed enabled the poet not only to contrast opposed natures, such as *Antigone* and Creon, but to introduce finer shades of difference, as between *Antigone* and Ismene, or Agamemnon and Odysseus. Perhaps the most notable instance of such delicate portraiture occurs in the *Philoctetes*, where Neoptolemus, the ingenious youth, is contrasted equally with the politic Odysseus and with the hero of the play, in whom a generous nature has been embittered by ill-treatment and solitude.

The *Ajax* may be described as the tragedy of wounded honour. Ajax and Odysseus had recovered the dead body of Achilles, whose armour, the miraculous work of Hephestus, was then awarded not to Ajax, the most valiant of the surviving Greeks, but to Odysseus, the wisest. Half-maddened by repulse, Ajax would have assassinated the generals; but, to defend Odysseus, Athena made the Telamonian warrior wholly mad, and turned his violence against the flocks and herds belonging to the army. On awaking from his delirium, finding his honour lost, he resolves on death. Agamemnon would have refused him burial; but Teucer vindicates him, and Odysseus, with becoming magnanimity, ends the strife. Tecmessa, the captive bride, who in her helplessness defies the Argives and protects the hero's child, is one of those female characters which Sophocles portrays with so much skill.

In the *Antigone* the claims of piety and natural affection are seemingly overborne by the exaggerated assertion of state-authority in the person of the ruler, but in the end it is the ruler who succumbs. The virgin martyr is vindicated.

In the *Electra*, in place of the fiery Theban maiden, the poet represents the faithful endurance of the Argive princess, who in the *Oresteia* of Æschylus had played a subordinate part, but here rises to the height of female heroism.

The *Œdipus Tyrannus* was regarded by Aristotle as the *chef d'œuvre* of tragedy, and nowhere else

is there to be found an equal combination of constructive ingenuity with tragic power. The hero is represented as the most loyal and affectionate, but also the most passionate, and, partly for that reason, the most unfortunate of men. Doomed to misery in his very birth, he appears to himself and others at the opening of the play to be at the height of prosperity. A stranger, he has earned the affection of Thebes, and lightly he undertakes the quest imposed by the god. In the sequel he discovers that he is the forbidden child of the king—whom he has slain—and of the queen—whom he has married! The poignancy and pathetic interest which Sophocles extracts from this unnatural story is a triumph of poetic skill. In the construction of the piece the employment of the Theban slave, who had been charged with the exposure of the child, and had also witnessed the death of Laus, is especially noteworthy.

The subject of the *Trachiniae* is the death of Heracles, but the fatal act of Deianira in sending the poisoned robe (which she believes to be a charm for recovering the affection of her lord) forms the central motive. She is one of the most charming of poetic creations, 'the rival of Imogen in purity, of Katharine of Aragon in her great patience, and of both in wifely spirit.'

There was an interval probably of at least ten years between the *Œdipus Tyrannus* and the composition of the *Œdipus at Colonus*, which indeed is said to have been exhibited for the first time only after the death of the poet. Meanwhile the genius of Sophocles had mellowed, and the spirit of the age had undergone some change. What in Euripides becomes a sort of moral casuistry appears in Sophocles at this period as a serenely contemplative mood immersed in ethical reflection. He has adorned the legend of his birthplace with undying beauty. But the moral dignity of the *Coloneus* is different in kind from the tragic fire of the *Tyrannus*.

The *Philoctetes* was produced in 409. It is a marvellous work for one in his eighty-seventh year to have composed. The characters are powerfully distinguished, and their mutual interaction is a new thing in dramatic poetry. Philoctetes, like the *Œdipus* of the *Coloneus*, is rejected by man, but accepted by the gods. Ill-usage and solitary musing have fixed in him the resolution never to return. The policy of Odysseus and the affectionate pleading of Neoptolemus are alike in vain, until the hard knot is loosed by the apparition of Heracles (in Euripidean style), who had been the hero's master and patron in the world of men. The interest of the action, which would else be stationary for so long, is sustained by the conflict in the soul of Neoptolemus, in whom ambition and public duty are struggling with pity for Philoctetes, and with the love of truth which the young chief inherits from his father Achilles. The victory of his better nature forms the culminating point in the action of the play.

Of other subjects known to have been treated by Sophocles those most suggestive of tragic interest are Alcæon, Atreus, Danaë, Hermione, Thamyra, Thyestes in Sicyon, Iphigenia, Clytemnestra, Creusa, Laocöon, Meleager, Niobe, Cnematus, Peleus, Telephus, Tereus, Troilus, Phædra, Phineus. The remaining fragments of these and other plays are on the whole disappointing. Sophocles even less than other poets can be fairly represented by isolated passages.

Amidst much variety, the dramatic work of Sophocles presents some constant features. Each play has a preliminary scene in which the main situation is set forth. This is followed by the entrance of the chorus, consisting of persons who stand in some well-considered relation to the chief agent. Then

fresh complications supervene, and the action rises in steady climax to the turning-point. The reverse of fortune is generally announced by a messenger, after whose speech the *kommos* or interchange of lamentation between the stage and orchestra naturally comes in. Between the scenes choice odes or *stasima* are interposed. But the lyric numbers are not confined to these. At suitable moments the chorus, and sometimes the actors themselves, break out into song, which on the part of the chorus is sometimes accompanied with dancing of a more or less animated description. This takes effect particularly in the *hypochemata*, or dancing-ode, which Sophocles is fond of employing at some conjuncture where the *dramatis personæ* have been deceived for the moment into a false and short-lived joy. This relieves the monotony of gloom while ultimately rather heightening tragic effect, by emphasising the contrast above noticed between appearance and reality.

Sophocles has not impressed the world with superhuman grandeur, as Æschylus has done. Nor has he charmed mankind by the witchery of style in particular scenes and descriptive passages, as appears to have been the case with Euripides. But to some of the greatest critics—e.g. Lessing—his merits as a dramatic artist have appeared to be supreme. The purely human note in tragedy is dominant for the first time in him. Matthew Arnold in an early sonnet described him well:

Be his
My special thanks, whose even-balanced soul.
From first youth tested up to extreme old age,
Business could not make dull, nor passion wild;
Who saw life steadily and saw it whole;
The mellow glory of the Attic stage,
Singer of sweet Colonus and its child.

If not quite holding the first rank with Homer, Æschylus, Dante, and Shakespeare, Sophocles is at least one of the immortals.

Sophocles was known to have written a satyric drama or farce called *Ichneutes* (*The Trackers*), based on the story how the infant Heimes stole Apollo's cows. Dr Hunt published in 1911, from a papyrus found at Oxyrhynchus, a fragment (400 lines) of a comedy on this theme, which, with other fragments found, is believed to be by Sophocles.

The *editio princeps* was printed at Venice in 1502. The long list of editors of the whole or part of the seven plays includes Brunck, Gottfried Hermann, Wunder, Dindorf, Schneidewin, Nauck, Bergk, Lobbeck (*Ajax*), Bockh, Meineke, Elmsley, Buttman, Linwood, Kennedy, Wolff, O. Jahn, Blaydes and Paley (2 vols. 1859-60), Lewis Campbell (2 vols. 1873-81), Tyrrell (1 vol. 1897), Sir R. C. Jebb (7 vols. 1884-96), and Pearson (1924; fragments, 1917). English translators are Francklin, Potter, Dean Plumptre, Sir G. Young, R. Whitelaw (1883), Prof. Lewis Campbell (1883), Prof. Phillimore (1902), A. S. Way (1909-14), Storr (1912-13), in verse; and Jebb and E. P. Coleridge, in prose. There is an excellent *Lexicon Sophocleum* by F. Ellendt (2d ed. by H. Genthe, Berlin, 1867-72), supplemented by an 'Index Commentationum' (1874). See Hense, *Studien zu Sophocles* (1880); Patin, *Études sur les Tragiques Grecs*; Prof. Lewis Campbell, *Sophocles* (1879), and *A Guide to Greek Tragedy* (1891); Schlegel's *Lectures*; Bishop Thirlwall's *Remains* (for a famous essay on the Irony of Sophocles); Mackail's *Lectures on Greek Poetry* (1926).

Soprano (Ital.), the highest species of voice. Its average range extends from C below the treble stave to A above it; but the greatest variety in compass and quality is found. The highest compass on record is that of Agujari, which on the testimony of Mozart reached to C in *altissimo* (three octaves). Music for this voice is now written with the G or treble clef; but in German full scores the old soprano clef, C on the first line, is still used. The *mezzo-soprano* has a somewhat lower range, usually from A beneath the treble stave to F on the fifth line. See VOICE.

Sora, a city of Italy, on the Liris or Garigliano, 55 miles E. by S. of Rome. Its position, as guarding the river valley and the entrance to the Abruzzi, has always given it importance. Remains of polygonal walls and mediæval fortifications may be noted on the rock above the town. It was the birthplace of the Decii, Attilius Regulus, and Lucius Mummus, and of Cardinal Baronius, the historian of the church. Pop. (1921) 17,612.

Soracte, an isolated limestone ridge, 2267 feet above sea-level, 5 miles SE. of Civita Castellana. It is mentioned by Horace (Od. i. 9), and appears to have been sacred to Dis Pater, the god of the underworld, owing to the deep chasms existing in its sides. A monastery was founded on the summit in 748 A.D. by Carloman, son of Charles Martel. The modern village of S. Oreste lies on its southern slopes.

Sorata, a volcanic peak of the Bolivian Andes, to the east of Lake Titicaca, rising to 21,490 feet above the sea.

Sorau, a town of Prussia, 60 miles by rail SSE. of Frankfurt-on-the-Oder, has three castles (one dating from 1207), a textile experimental station, some good churches, and manufactures of cloth, linen, cigars, &c.; pop. 17,000.

Sorb. See SERVICE; SLAYS.

Sorbonne, the earliest, as it was by far the most famous, of all the colleges of the mediæval university of Paris. The system of colleges, of which the Sorbonne was the first example, dates only from the later part of the 13th century, more than a hundred years after the beginnings of the university itself. The system sprang out of the necessity for the adequate accommodation of the vast numbers of students who flocked to Paris from all the countries of Europe. Previous to the erection of colleges the students had mainly to content themselves with such lodging as they could find, and experience had shown that they had suffered both in their purse and their morals from this system.

It was the happy inspiration of Robert of Sorbon, in the diocese of Reims, to conceive and carry out the idea of combining a place of residence and a place of study. With the consent of St Louis, to whom he acted as chaplain, Robert founded the college of the Sorbonne in 1253, though it was not formally opened till 1256. By a bull of Clement IV. (1268) the new institution received the indispensable sanction of the pope as the head of all the mediæval universities. At the head of the college was the *provisor*, who was chosen by the whole university, though its business was mainly in the hands of the *prior*, elected every year from the members of the college itself. The members were divided into two classes, *Hospites* and *Socii*. The Hospites received the full benefit of the educational provisions of the college, but they had no part in its administration. On the attainment of the doctorate in theology at the age of thirty-five their residence came to an end. The Socii, who were restricted to the number of thirty-six, had the entire management of the college in their hands, and all, whatever their age or academic rank, were on a footing of absolute equality. The life of the college was according to the strictest monastic rule, and its inmates with proud humility styled themselves 'the poor masters of the Sorbonne.'

The Sorbonne was exclusively devoted to the study of theology, and no student could enter it till he had taken the diploma of Bachelor of Arts, and had sustained a thesis, known as the *Sorbonica* or *Robertina*, before all the members of the college. The discipline through which he had then to pass was the severest in all the Paris colleges. It was above all by the system of disputation that his

progress was stimulated and his proficiency tested. By its rigorous methods of conducting these disputations the Sorbonne gained the reputation of being the first theological school in Europe; and its opinion on disputed points of doctrine was universally accepted as the weightiest that could be obtained. In affiliation with his larger college Robert of Sorbon in 1271 also founded a smaller college—that of Calvi, or the Little Sorbonne—where students were prepared in subjects preliminary to their study of theology. It was the distinctive feature of the Sorbonne, however, and one which greatly helped to win for it its predominance in the university, that its members were drawn from every country in Europe, and not confined to a particular 'nation.'

The history of the Sorbonne is a signal instance of a great institution admirably fulfilling its original intention, but incapable of making a new departure when such a departure was necessary for its continued vitality and efficiency. Till the close of the 15th century, when the scholastic theology was fast losing its hold on all the best minds, the Sorbonne filled a place of the first importance in the intellectual life of Europe. Throughout the middle ages the theological faculty of Paris was the main support on which the highest teaching had rested, claiming for itself the right, denied to the pope himself, of sovereign decree on the truth or falsity of all religious doctrine. But the Sorbonne virtually constituted the theological faculty, and in common speech was identified with it. Its voice therefore carried an authority that influenced the councils of the nation. Through its efforts France was saved from Peter's Pence and the Inquisition; and it was due to its encouragement that printing was introduced into Paris immediately subsequent to its invention.

From the beginning of the 16th century, when the new studies of the Revival of Learning found their way into France, the Sorbonne gradually ceased to represent the best thought of the country. To all reform alike in studies and religion it offered the most dogged resistance, and it was largely due to its action that Paris lost its place as the first school in Europe. Among the men of the new order the 'Sorbonnian bog' became a byword for bigotry and obscurantism. In the succeeding centuries the Sorbonne followed the same retrograde policy. In 1621 it actually obtained an edict, mainly directed against Descartes, forbidding all teaching that ran counter to accepted authorities. On the occasion of the erection of new buildings by Richelieu (1627), who was provisor of the college, a satirical Latin couplet declared that so long as its original home was in decay the Sorbonne was unassailable, but now that that home was renewed it would certainly go to ruin. The butt of the wits of successive generations, Boileau and Voltaire among the rest, the Sorbonne clung to its original traditions till at the Revolution (1792) its property was confiscated to other objects.

When in 1808 Napoleon reorganised the university of France, the Sorbonne was revived and became the seat of the *Académie* of Paris (see UNIVERSITY) and of the three faculties of theology, science, and literature. In 1884-1900 a new set of buildings was erected to take the place of the college erected by Richelieu. The theological faculty was removed in 1885.

See the various histories of the university of Paris by Du Boulay, Crevier, and Denifle; also Duvernât, *Histoire de la Sorbonne* (2 vols. Paris, 1790), and Franklin, *La Sorbonne* (Paris, 1875).

Sorcery. See MAGIC, WITCHCRAFT.

Sordello, an Italian troubadour named by Dante and exalted to a hero in Browning's poem,

wrote love songs, satires, and a didactic poem. In 1226, while in the service of Richard of Bonifazio at Verona, he abducted his master's wife, Cunizza, sister of Ezzelino da Romano (q.v.), fled to Provence, and died about 1270 in the service of Charles of Anjou. See the edition (with Life) in Italian of his works by Cesare de Lollis (Halle, 1896), and a book by Eugene Benson (1903).

Sorel, a town of Quebec, on the St Lawrence, 45 miles NE. of Montreal. The industries include shipbuilding, founding, engineering, pulp and saw milling, leather. Pop. 8000.

Sorel, AGNES, the mistress of the worthless dastard Charles VII. of France, born about 1422 in the village of Fromenteau in Touraine, early entered the service of the Duchess of Anjou. Her influence with Charles began in 1444, but she died suddenly in 1450. See Life by Duquesne (1909).

Sorel, ALBERT (1842-1906), born at Honfleur, served in the French foreign office and in the secretariat of the president of the senate, and wrote much on history, specially his great *L'Europe et la Révolution Française* (8 vols. 1885-1904).

Soresina, a town of Northern Italy, 16 miles by rail NW. of Cremona, with silk-mills and 11,000 inhabitants.

Sorghum. See DURRA, SUGAR.

Soricidæ. See SKEW.

Sorolla, JOAQUÍN (1863-1923), Spanish artist, was born of humble parents at Valencia, and after studying at the Academy of Art at Valencia, won scholarships to Rome and Paris. With sincerity, sympathy, and spontaneity he depicted nearly all aspects—aristocratic portraiture, scenes of rustic life, sunlit seascapes, &c.—of contemporary Spain. He developed the technique and methods of French Impressionism with great brilliance, his style being eminently swift, direct, and always natural.

Sorrel (*Rumex*), a genus of plants of Polygonaceæ (q.v.), divided into two sections, the first of which is noticed at DOCK. Sorrel, the second, is characterised by diocious flowers and acidity of stems and leaves. Common Sorrel (*R. Acetosella*)

is a perennial found in meadows and pastures throughout the whole of Europe, and is very plentiful in Britain. Its stem is from a foot to two feet high, its leaves arrow-shaped. It is an agreeable salad, and is used in soups and sauces and as an addition to dishes of greens. It is therefore sometimes cultivated in gardens. French Sorrel, or Roman Sorrel (*R. scutatus*), a native of South Germany, Switzerland, France, and Italy, has broader and blunter leaves, and is more frequently cultivated than Common Sorrel, being considered of finer flavour. Sheep's Sorrel (*R. Acetosella*) is a very similar plant, but of much smaller size, and its roots run very much

Common Sorrel.
Rumex Acetosella.

under ground, so that it is a very troublesome weed in gardens and fields of poor dry soil, in which it is very common in all parts of Britain. *R. Patientia*

and *R. sanguinea* are both regarded on the Continent as good spinach plants. For Wood-sorrel, a totally different plant, see OXALIDACEÆ. For the Red Sorrel of the West Indies, see HIBISCUS.

Sorrel Tree (*Oxydendron arboreum*), a small tree of the family Ericaceæ, which grows chiefly on the Alleghany Mountains. The leaves are acid, and are sometimes used for dyeing wool black.

Sorrento (Lat. *Surrentum*), a city of Italy, on the south-east side of the Bay of Naples, on the promontory which separates it from the Gulf of Salerno, 10 miles SW. of Castellamare. It is an archiepiscopal see. The manufacture of silk and the inlaying of wood are extensively carried on. It is celebrated for the mildness and general salubrity of its climate, for its beautiful situation in the midst of orange-groves and fruit-gardens, and for the picturesqueness of the adjacent coast; on these accounts it is much resorted to by winter and summer visitors. In the time of Augustus it was noted for its fine buildings; but few traces of these now exist in the town itself, though there are extensive ruins of villas on the promontory, notably of that of Pollius Felix, the friend of Statius. Among the Romans the wine of Sorrento was held in high repute, as were its fish and its red Campanian vases. Torquato Tasso was born here in 1544. Pop. (1921) 9783.

Sortes Virgilianæ, a favourite mode of divination among the ancients, in which an oracular answer was found in a doubtful juncture by opening Virgil's *Æneid* at random, and pricking a pin into the book, or taking the first passage on which the eye chanced to rest. Another method was to take a number of his verses, shake them together in an urn, and draw out one, from whose contents to infer good or evil. The ancient Sibylline oracles naturally afforded a subject, and the strange magical reputation early attached to Virgil helped to make his great poem the book most frequently used for this purpose. The mediæval mind read Christianity into Virgil, and consequently found no difficulty in ascribing equal value to the *Æneid* and the Bible for purposes of divination. We are told that Severus fore-read his high destiny in the line, 'Tu regere imperio populos, Romane, memento;' and Gordianus, who was to reign for but a few days, read his doom in the words, 'Ostendunt terris hunc tantum fata, nec ultra esse sinunt.' Gundulf, afterwards bishop of Rochester, and two other monks one day at Caen turned over the pages of a book of the gospels to read their future fortunes, and the Abbot Lanfranc foretold from Gundulf's passage that he should yet become a bishop. Rabelais found his license to escape from the bondage of the convent in the line, 'Heu! fuge crudeles terras, fuge littus avarum;' and we may see all the weakness of this method in the perplexity of the answers it yielded in the great question of Panurge's marriage. Dr Welwood tells us that Charles I. and Lord Falkland once made experiment of their future fortunes at the Bodleian in Oxford, and found passages equally ominous to each. The lines which the king read (*Æn.* iv. 615-620) from Dido's imprecation against *Æneas* plainly foretold rebellion, defeat, and a shameful death; Falkland opened at Evander's lamentation over the untimely death of his son Pallas (*Æn.* xi. 152-181). Unfortunately for this beautiful story, Aubrey in his *Remains of Gentilisme and Judaism* tells it of Prince Charles and the poet Cowley at Paris just before the trial of the king. At any rate Cowley himself tells us that he found some light from Virgil about the Scottish treaty, when employed as a secretary in affairs of state; and we read

how the Lord Chamberlain used the passage in 2 Chron. xix. 5-8 during Charles I.'s miserable Sunday of hesitation about the execution of Strafford to convince the king that the responsibility really rested upon the judges. Sir Thomas Browne in his *Vulgar Errors* denounces the *Sortes* as an ancient fragment of pagan divination; and Dr Nathanael Home, in his *Dæmonologie* (1650), deplors the loss to the state and the sin to the church engendered through lots by sieves and books.

The early Christian writers denounced divination by lots as magical, and therefore a form of idolatry. Still the practice continued to be common — 'per sortes sanctorum,' by the first passage found in the psalter or gospel, the lectionary or sacramentary. St Augustine condemned this as an abuse of the divine oracles, yet preferred to see men turn in this way to the gospels rather than to demons. And we find that an unsought omen from a psalm ended the opposition to the choice of St Martin as bishop of Tours. The *Sortes Apostolorum* was a collection of pious sentences much employed for divination, a bread and water fast of three days being prescribed before using it. A similar use of the Bible long survived amongst Protestants, and indeed is not to this day extinct among people of simple faith in corners of England and Germany. A characteristic instance is told of his own experience by the great Cambridge evangelical leader, Charles Simeon, when downcast about the opposition to his ministry in his earlier years. 'I prayed that God would comfort me with some cordial from His word, and that, on opening the book, I might find some text which should sustain me. It was not for direction I was looking, for I am no friend to such superstitions as the *Sortes Virgilianæ*, but only for support. The first text that caught my eye was Matt. xxvii. 32. . . . Simon was the same as Simeon. What a word of instruction was here, what a blessed hint for my encouragement!' The obstinate survival of this superstition depends upon the naturalness of the notion, where there is a strong conviction of the power and watchful care of an overruling Providence, and a belief in the Bible as the literally inspired hand-book of divine guidance to man. Bibliolatry makes the notion of such divination perfectly rational, and we may well believe that its disuse has been merely a consequence of the decaying respect for the mere letter of Scripture. See DIVINATION.

Sorus. See FERNS.

Sosnovice, a town of Poland, 160 miles SW. of Warsaw, with iron, textile, and chemical industries; pop. 86,000.

Sotchi, a town of Georgia, in the Black Sea Riviera, with hot sulphur springs in the neighbourhood; pop. 13,000.

Soteriology, that part of theology which treats of salvation by a redeemer (Gr. *sōtēr*). See ATONEMENT, CHRIST, CHRISTIANITY, JESUS CHRIST.

Sothern, EDWARD ASKEW, comedian, was born in Liverpool, 1st April 1826, and, declining the church, medicine, or the bar, in 1849 joined a company of players in Jersey, and soon afterwards passed into the stock company of the Theatre Royal, Birmingham. From 1852 he appeared in the United States, without much success, until in 1858 *Our American Cousin*, by Tom Taylor, was brought out in New York, with Sothern cast for the small part (forty-seven lines) of Lord Dundreary. The piece was a poor thing, and the character of the English peer as playgoers knew it was Sothern's own creation, bit by bit. In November 1861 the play was produced in London, at the Haymarket, and ran for over 400 nights;

and it was again and again revived in later years. Sothern essayed many other characters, but he is remembered chiefly as Dundreary; his other most memorable parts were David Garrick in Robertson's comedy, and perhaps Fitzaltamont in *The Crushed Tragedian*; the latter failed utterly in England, but was always popular in America, whither Sothern returned several times. He died in London, 21st January 1881. See the *Memoir* by T. E. Pemberton (1890).

Souari. See CARYOCAR.

Soubise, an ancient French family, whose property and title came in 1575 into the house of Rohan by the marriage of their heiress, Catheline de Parthenay, with the Vicomte René II. de Rohan. Memorable as champions of the Huguenot cause were both sons of this marriage, the elder, Henri, Duc de Rohan (q.v.), and the younger son, Benjamin de Rohan, to whom the seignieury of Soubise fell as heir of his mother. The latter was born about 1589, served under Prince Maurice in the Low Countries, and in the religious war commanded the Huguenots in Poitou, Brittany, and Anjou, and distinguished himself throughout by his reckless courage, especially in the bold attack on the royal fleet in the harbour of Blavet and the occupation of Oleron. When all hope was at an end he found a refuge in England, and died in London childless, 9th October 1642.—In the collateral line of descent was Charles de Rohan, Prince de Soubise, peer and marshal of France, who was born 16th July 1715. His grandmother had been a mistress of Louis XIV., and he himself became a favourite of Louis XV., and early in the Seven Years' War was given the command of an army of 24,000 men, which was utterly defeated by the great Frederick at Rossbach, 5th November 1757. His later exploits were less disastrous; he even won some small successes, and he kept the command until the peace in 1763. After the death of Madame de Pompadour he found a patroness in Dubarry. When Louis XV. died he was the only one among the courtiers who followed his body to the grave—a piece of loyalty which made the new king retain him in his place in the ministry. He died 4th July 1787, and with him ended the line of Soubise-Rohan.

Soudan. See SUDAN.

Soul, a term used with various significance both in philosophical terminology and in the language of everyday life. Soul is sometimes the immaterial and immortal part of man as opposed to his body; soul is sometimes distinguished from intelligence as the resolute, energetic, emotional from the calmly contemplative; and when soul and spirit are contrasted, the soul is the lower phase of conscious life (sometimes the animal soul) as contrasted with the highest, noblest, and godlike element. A like confusion obtains in other languages; the German *Seele* and *Geist* are opposed nearly as life principle to mind, and as the emotional to the intellectual and spiritual. The confusion dates from the early times of Greek philosophy. In general, *psychē* (usually translated 'soul') is opposed to *nous*, 'intelligence,' and also, especially in religious philosophy, to *pneuma*, 'spirit,' the divine element in man. Plato (q.v.) divided the soul into (1) the rational, (2) the spirited or irascible, and (3) the appetitive elements. With Aristotle the *psychē* is practically the vital

principle in plants as well as animals. In Neoplatonism (q.v.); and see also PLOTINUS) the psychical side of man was treated with disrespect as the part to be mortified. The doctrine of a world-soul has its roots in early speculation (see ANIMA MUNDI), and connects with some types of Pantheism (q.v.); see also MICROCOSM. Opposing views as to the origin of the individual soul, creationism, and traducianism are explained in the article dealing with the belief in Pre-existence (q.v.). See also the articles PSYCHOLOGY, PERSONALITY, IMMORTALITY, REINCARNATION, APPARITIONS, SECOND-SIGHT, HELL, ANIMISM, and those on the great authors named at PHILOSOPHY.

Soult, NICOLAS-JEAN DE DIEU, Duke of Dalmatia, and Marshal of France, was born the son of a notary at Saint-Amans-la-Bastide, in the dept. of Tarn, March 29, 1769. In 1785 he enlisted as a private in the Royal Infantry regiment, and was only sergeant after six years' service. Thereafter, however, his rise was rapid; in 1792 he became adjutant-major, and his conduct at Fleurus gained for him (October 1794) the brevet of general of brigade. From 1794 to 1799 he was in constant service on the eastern frontier and in Germany, and in the retreat after the defeat of Stockach (March 25, 1799) it was his able handling of the rear-guard alone that prevented the annihilation of the French army. The new chief Masséna made him general of division (April 1799), and owed to his courage and capacity much of the glory of his Swiss and Italian campaigns. In 1802 Soult was appointed by Napoleon one of the four colonels of the consular guards; in 1804 a marshal of France. He led the emperor's right wing in the glorious campaign closed with the crowning victory of Austerlitz, which he decided by piercing the Russian centre. He also did good service in the Prussian campaign, and took an important though not a prominent part in the Russian campaign of 1806-7, and after the peace of Tilsit was created Duke of Dalmatia. Soult was next placed at the head of the second corps in Spain, pursued the retreating British, attacked them at Corunna, and, though repulsed, forced them to evacuate the country and leave their stores behind. He then conquered Portugal, and governed it till the sudden arrival of Wellesley at Coimbra made him retreat rapidly to Galicia. In September 1809 he became commander-in-chief in Spain, gained a brilliant victory at Ocaña (18th November), and at the commencement of the following year overran and subdued Andalusia, continuing to command in person the southern army. In attempting to succour Badajos, which he had captured and garrisoned (March 11), he was defeated by Beresford at Albuera (May 16, 1811). After the battle of Salamanca and the advance of the British on Madrid, Soult, mortified at the obstinacy of Joseph Bonaparte and the rejection of his admirable plans for transferring the theatre of war to Andalusia, demanded and obtained his recall; but Napoleon, as soon as the tidings of Vittoria reached him, sent him back to the command in Spain, as the only captain capable of turning the tide of ill-fortune. By brilliant tactics he neutralised the consummate strategy of Wellington, and reduced the seven months' campaign to a mere trial of strength, the defeats which he sustained at Orthez and Toulouse being due to the superiority of the British soldiers, not of their general. With his usual suppleness of character, he became an ardent royalist after the abdication of Napoleon; but on the return of the latter from Elba he threw over Louis XVIII. to become

major-general of the imperial army. After Waterloo he rallied the ruins of the army at Laon, and at the council of war (July 3) coincided with Carnot as to the uselessness of further resistance. He was banished and not recalled till May 1819, but within a few years he was restored to all his former honours. In 1838 he was sent as ambassador to England to the coronation of Victoria, and was received by Wellington with warmth and by the nation with enthusiasm. In 1845 he retired from active duty, and was honoured with the appointment of 'Marshal-general of France'—a rank held before him only by Turenne and Villars. He now retired to Soultberg, his château near his birthplace, where he died, November 26, 1851.

See Soult's *Mémoires*, written in 1816 at Düsseldorf (3 vols. 1854); also Napier's *History of the Peninsular War*; Thiers's *Histoire de la Révolution et de l'Empire*; Salle's *Vie Politique du Maréchal Soult* (1834); and Combes's *Histoire Anecdote* (1870).

Sound, in ordinary language, is that which appeals to us through our organs of hearing. Experience teaches us that almost every sound can be traced to a source outside of us, and that as a rule the sound is characteristic of the source from which it comes. Different voices are easily recognisable, and there is no difficulty in distinguishing a trumpet-call from a violin-note. Here we have brought out the *quality* or *timbre* or colour of a sound. Another very obvious characteristic is the *pitch* of a sound. On it the whole theory and practice of music is based. Even the most unmusical ear can distinguish between a deep-toned note and a shrill one, between, for example, the extreme notes on a piano or organ. Then there is the question of the *intensity* or loudness of a sound. In terms of these three fundamental characteristics all differences of sound can be expressed. It is the object of the science or theory of sound to investigate the physical or mechanical nature of whatever under suitable conditions can be heard by the ear, and to express in terms of motion of matter these three ever-present characteristics—quality, pitch, and intensity.

Generally speaking, the air is the medium through which sound travels towards us. Whatever be the sound-producing body, it must first transfer something to the air, which in its turn conveys a corresponding something to our ear. Within us the sensation produced is a purely subjective one, and must not be confused with the objective cause existing outside of us. There is, however, a distinct relation between the two; for when the external conditions are physically identical, so are the resulting sensations. The very fact that air can transmit to us such a variety of sounds shows that it is capable of responding more or less completely to the varied characteristics of the sound-producing body. The necessary condition for the production of sound is that the body must, by its own vibrations or in some other way, set the air into vibration. Bells, tuning-forks, violin-strings, and drums are familiar instances of vibrating bodies; but if these are made to vibrate *in vacuo* no sound will be heard. Vibrating in air they give forth their appropriate sounds. In the Siren (q.v.) we have an instrument which produces sound by breaking up a continuous blast of air into a succession of pulses. The instrument is valuable as proving that the pitch of a note depends on the number of pulses per second. The faster the siren spins, the more quickly the pulses follow each other, the greater is the *frequency* or number of pulses per second, and the higher is the pitch, as the ear at once tells us. The same fact can be proved by holding the edge of a card against the teeth of a revolving toothed wheel. If the

wheel is going fast enough, the successive noises of the card as it frees itself from each tooth and impinges itself on the next succeeding are no longer distinguishable, but coalesce to produce a note of definite pitch which rises as the wheel rotates faster. Now it may be shown that, when the ear is satisfied that the notes produced by a siren and a tuning-fork have the same pitch, the number of pulses given by the siren in one second is exactly equal to the number of vibrations of the tuning-fork in the same time. Thus the vibrating tuning-fork transfers to the air a series of pulses timing accurately with the vibrations. It is not difficult to see how this takes place. As the forks vibrate to and fro they push the air first on one side and then on the other; and just as a hand moved slightly to and fro in water starts a series of waves travelling outwards along the surface, so the tuning-fork starts in the air a series of waves of condensation and rarefaction which travel outwards through the air. In the case of the water-waves gravitation supplies the force which, by its tendency to keep the surface level, gives the power of recovery that is indispensable to all wave-motion. In the case of the sound-waves the air's own Elasticity (q.v.), or power of resisting change of bulk and of recovering completely its original density, is the essential factor in producing and sustaining the wave-motion (see WAVE).

The essential features of the wave-motion in the air may be indicated by the behaviour of a row of points, each of which oscillates to and fro about its mean position. The time or period of oscillation is the same for all; and we shall suppose the oscillations to be of the simplest type known as Simple Harmonic Motion (see WAVE). When at rest the points are all at equal intervals apart, as in fig. 1, *a*. When in motion so that each point moves through its mean position a little later than

a
b
c
d

Fig. 1.

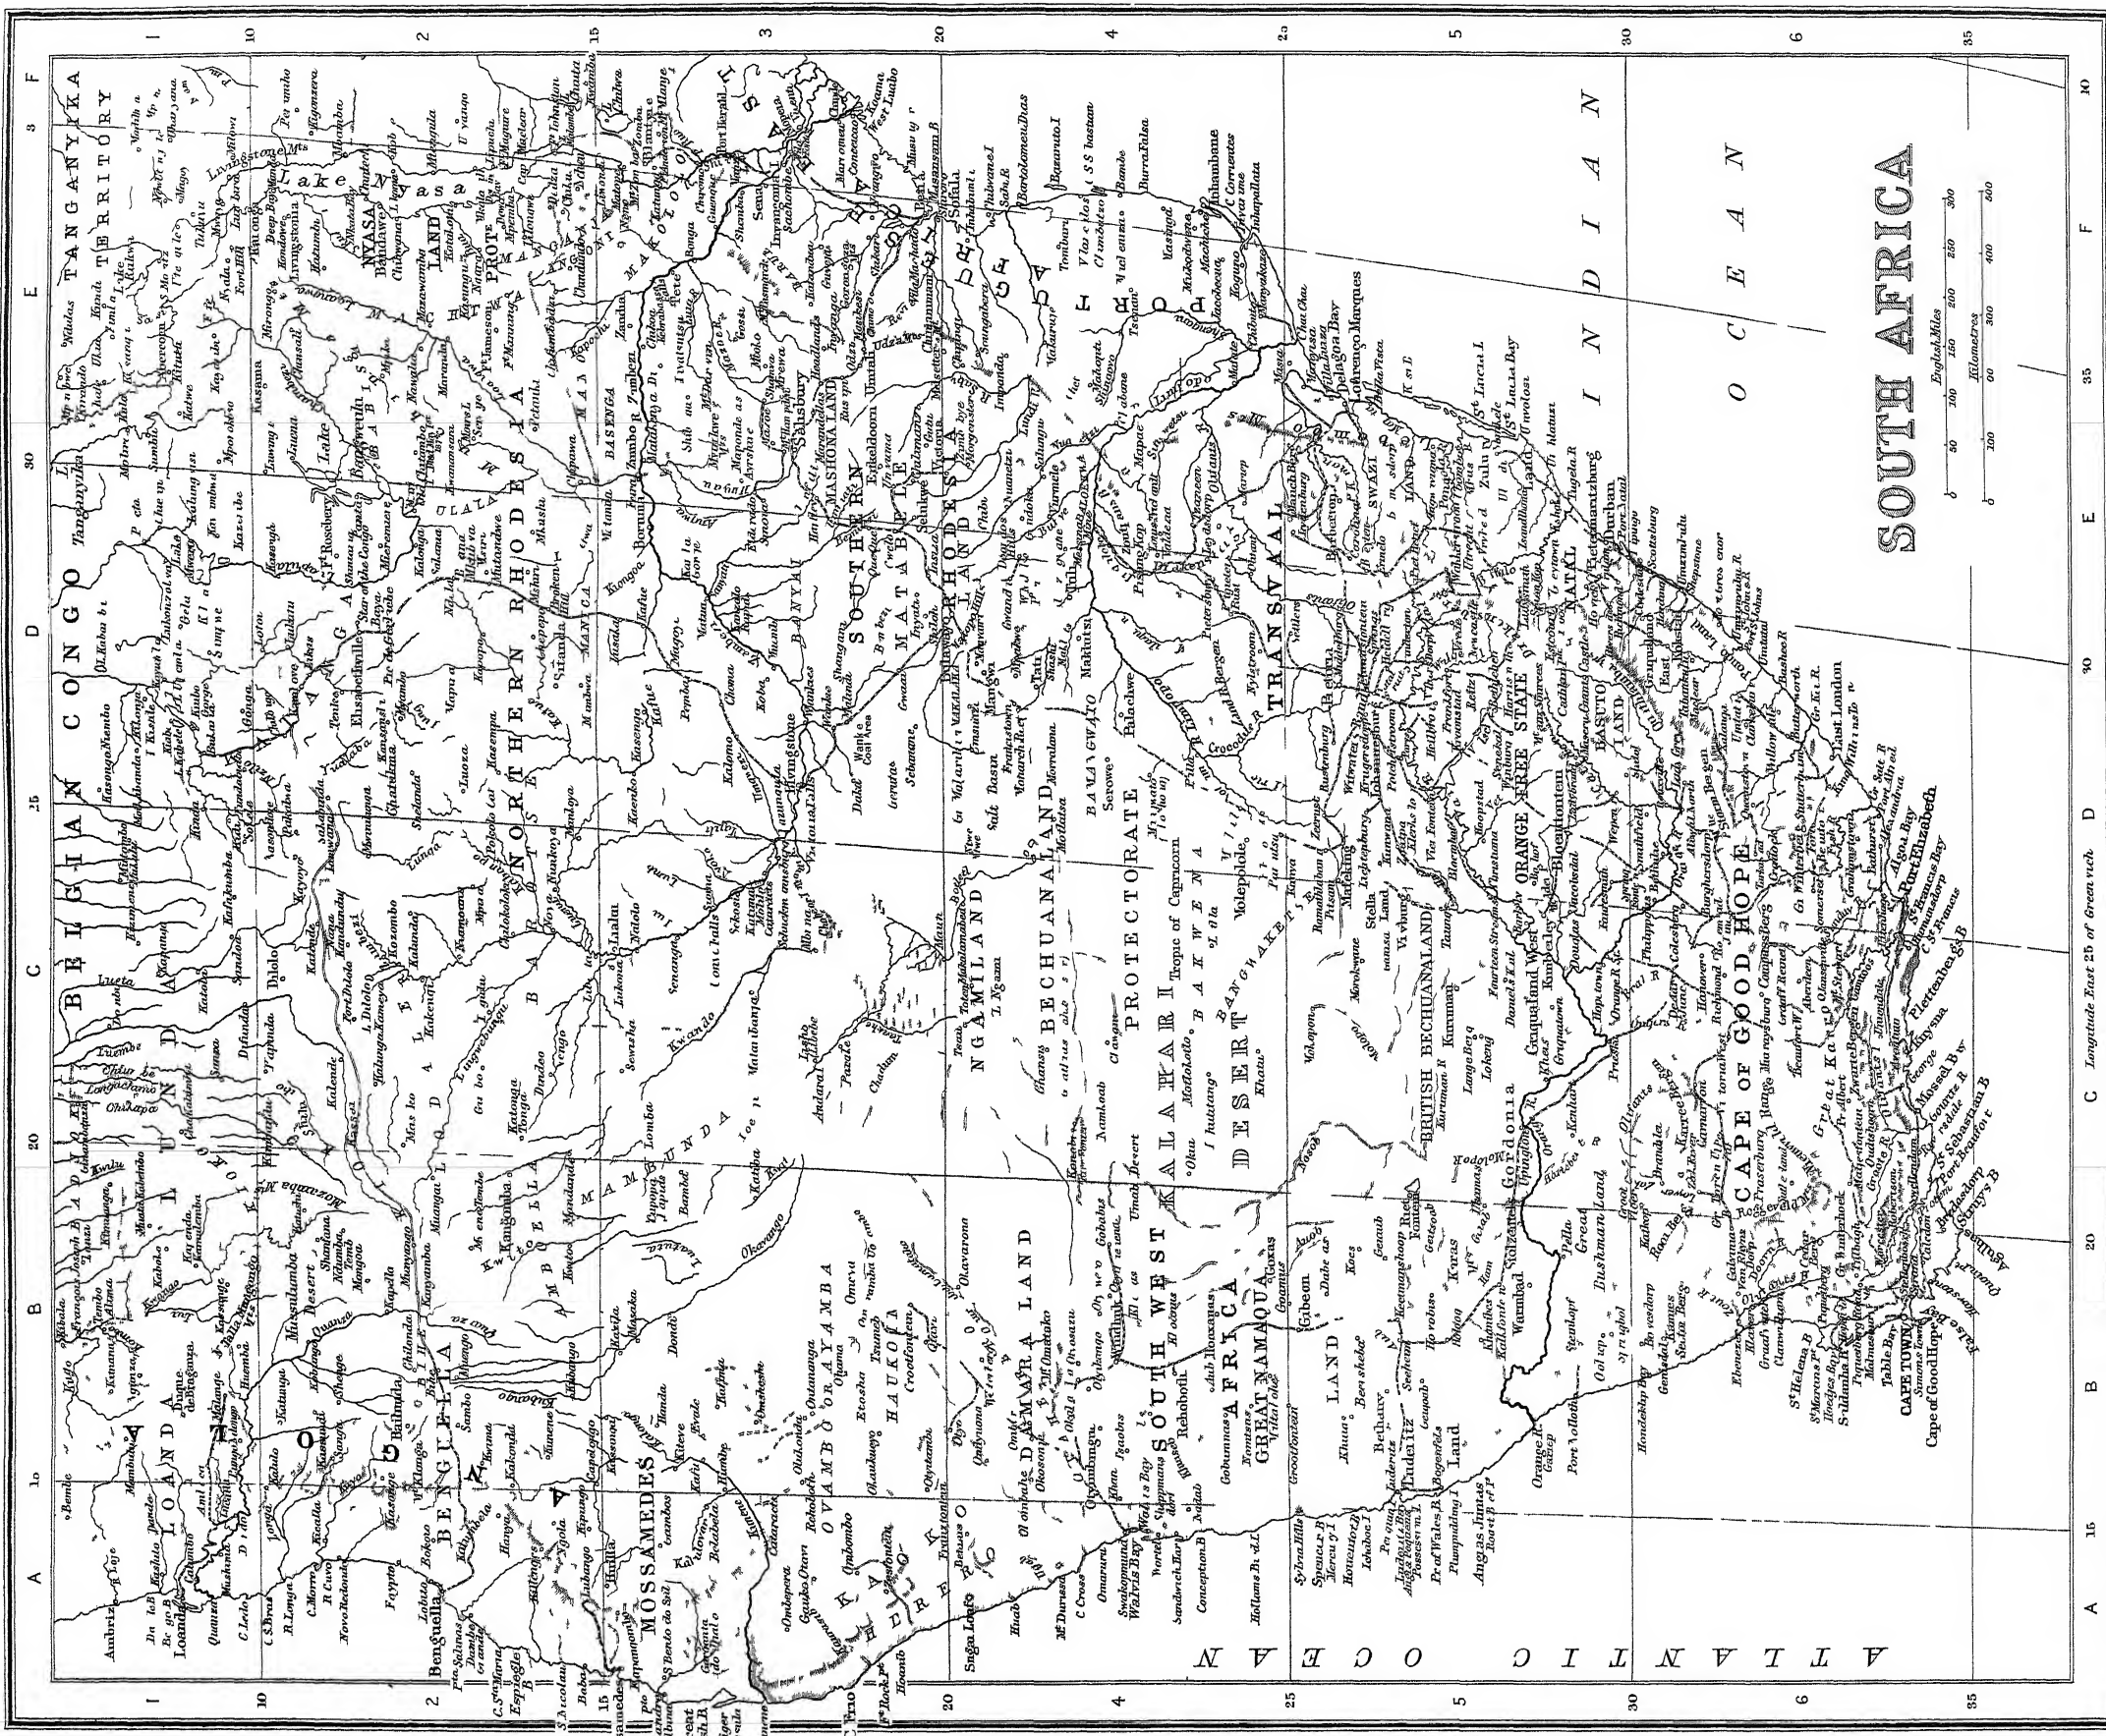

does the immediately preceding point, then the points will be crowded together in some regions and widely distributed at others (fig. 1, *b*). As the points continue their oscillations the configuration will not remain steady, but will move along among the points (fig. 1, *c* and *d*). Any given region will become alternately more crowded and less crowded, a region now of condensation, now of rarefaction. This ever-changing condition, which we have supposed to be the characteristic of a row of points, may easily be imagined to be possessed by a swarm of space-filling particles; and, from the analogy of the circular ripples which expand outwards over the surface of a lake which has been disturbed by a stone being dropped into it, we can readily picture a succession of spherical waves of condensation and rarefaction radiating out through air from the source of disturbance, in the present instance the source of sound. The mode by which the condensation or rarefaction is passed on from one region of air to another may be explained as follows: Because of its elasticity air resists compression and will tend to recover its original density as soon as the compressing force is removed. But because of its inertia it will, if left perfectly free, overdo the recovery—just as a pendulum when drawn aside and let go swings to the other side of its natural position of rest. Now if any small region of air undergoes rarefaction it can only do so by itself expanding and thereby compressing the surrounding layer of air. But as it, so to speak, swings back through its condition of

normal density to a state of condensation, the surrounding layer will swing from its state of condensation to a state of rarefaction, that is, expansion, compressing thereby in its turn the next encompassing layer of air. This second layer, having thus acquired an oscillatory character, will in the same way impress the next layer with a like character, and so on indefinitely.

Returning to the case of the tuning-fork, we see how the energy of its vibrations is gradually transferred to the air and transmitted through it to the farthest limits at which the sound is heard, if not farther. Thus the motion of the tuning-fork gradually decays, and the intensity of the sound heard at any given distance simultaneously diminishes. Ultimately the sound dies away, and the tuning-fork comes to rest. What is called the intensity of a sound depends in some way upon the degree of agitation communicated to the air—in accurate language, upon the vibratory energy existing in the air at the place where the sound is heard. Now it is a familiar experience that with great variations of intensity the pitch of a sound remains unchanged. The pitch depends upon the number of vibrations per second, and the intensity upon the energy of vibration. We find then that within wide limits the extent or amplitude of the vibration, or (as in air) the range through which the density may vary, does not affect the periodic time of the vibration. The quantitative relation between the energy and the amplitude, and therefore between the intensity and the amplitude, is that the former varies as the square of the latter. With double the amplitude we have four times the intensity, with half the amplitude one-fourth the intensity. That the intensity falls off at a much quicker rate than the amplitude is at once evident to any one closely inspecting the diminishing range of motion of a tuning-fork and at the same time paying attention to the decreasing loudness of the tone. The ear is by no means so sensitive in comparing intensities as it is in comparing pitches. When two notes are of very different pitch it is often difficult to say which is the louder.

We now pass to the consideration of the quality of a musical sound. A tuning-fork gives a colourless inexpressive sound, whose one useful property is the constancy of the pitch. When sounding the same note the pianoforte, the violin, the trumpet, the clarinet, and the human voice all impart their own peculiar flavour, which is readily recognised by the ear. Not only so, but we can distinguish different pianofortes, different violins, different voices, and so on. These differences of quality cannot depend on the frequency or number of vibrations per second, for that determines the pitch; nor upon the energy of vibration, for that determines the intensity. Quality, in fact, can depend only on the internal nature of the vibration. This may be shown synthetically, as was done by König, by making siren disks, each perforated with its own peculiar shape of hole, but all identical as regards number of holes and rate of rotation. It is evident that if the blast of air is broken up into successive portions which have issued through, say, triangular instead of the usual circular holes, the form of the pulses which build up the note will be changed. And such a change is recognised at once by the ear.

Most instructive in this connection are the laws of vibration of stretched strings. If we fix one end of a pretty long rope to a wall, and, with the other end in the hand, keep it in a stretched condition free of the floor, we may observe any slight disturbance given to it running as a solitary wave along the rope and back again after reflection at the wall. The tighter the rope is stretched the quicker will this disturbance travel to and fro along it. It is

SOUTH AFRICA

not difficult to show that the speed at which such a disturbance or wave will travel along a stretched cord depends on the tension (T) and on the mass (m) per unit-length of the cord, being given by the simple formula $v = \sqrt{T/m}$. Suppose we have such a stretched cord of indefinite length, and that a series of exactly equal waves are running along it from left to right, as shown in fig. 2, a , in which the straight line indicates the undisturbed position of the string. Now let there be propagated along the string from right to left an exactly equal series of waves, which, if existing alone, would throw the string into some such form as shown in b (fig. 2).

Fig. 2.

The superposition of these two exactly similar series of waves propagated in opposite directions gives rise to a resultant motion indicated in c (fig. 2). Here the points ABCDEF, being once at rest, are always at rest; since, whatever be the displacement due to the a waves, an exactly equal and opposite displacement is produced by the b waves, now and forever. Intermediate points, however, will move up and down between the limits indicated by the dotted loops in c (fig. 2). The string, in fact, will vibrate in segments whose ends are fixed at the points ABCDEF. The segments will be, at any instant, alternately above and below the undisturbed position of the string. The motionless points are called *nodes*; and it is evident that we may fix any two of them, and cut away all the string lying beyond these chosen nodes without in any way affecting the motion of the part lying between them. If we fix two contiguous nodes, for example A, B, we have a definite length of string vibrating as a whole. If A and C are fixed we get twice that first length of string vibrating in two segments; if A and D, we have three times the length vibrating in three segments; if A and E, four times the length vibrating in four segments; if A and F, five times the length vibrating in five segments; and so on. Now all these are simply different ways of producing exactly the same vibration, so that a note which is given by one length of stretched string vibrating as a whole may be given by L lengths of a similar string similarly stretched, vibrating in L segments. But we may have this string of length L itself vibrating as a whole. We have merely to suppose the oppositely directed series of waves to be L times longer than those shown in fig. 2 (a, b). If n is the frequency of any vibration, and l the wave-length or distance from crest to crest, it is easy to see that a given wave will travel over a distance nl in one second. That is, we have $nl = v = \sqrt{T/m}$, a quantity depending only on the tension and mass of the string. Consequently, if we double the wave-length we halve the frequency; if we halve the wave-length we double the frequency; and so on. Generally then the frequency of vibration of a string of given tension and density varies inversely as its length. This is the principle on which all instruments of the violin and guitar types are played. The player, by pressing the string down with the finger at different points, can shorten the string in the required ratio, thereby producing a correspondingly higher note.

From what precedes we see that a stretched string, which vibrates as a whole, say, 100 times per second, can also vibrate 200 times per second in two segments, 300 times per second in three segments, and, in general, n hundred times in n segments, if the segments are not too short. By lightly touching, without pressing, a violin-string at the proper point, so that that point is made a node, any of these higher notes (overtones) may be obtained. This is a very common practice in playing the violoncello. Not only, however, may a string be so made to utter any of the overtones, but it is practically impossible to prevent some of them sounding along with the fundamental note. It is, in fact, upon the presence of these overtones that the quality or character of the sound depends. They give the *form* to the vibration. In fig. 3 we see how the form of the wave is changed by superposing upon a given vibration the first and second overtones, having frequencies twice and three times the frequency of the fundamental tone. The musical relations of these overtones of stretched strings are discussed under HARMONICS (q.v.). The harmonics of a note are the simple harmonic vibrations

Fig. 3.

into which, according to Fourier's analysis, any steadily recurring periodic motion can be decomposed. The prime or fundamental tone is the first harmonic; and higher harmonics are all overtones. But, as we shall see hereafter, all overtones are not necessarily harmonics.

Air-columns, such as we have in organ-pipes (see ORGAN), vibrate according to laws very similar to those which rule the vibrations of strings. The frequency of the note is inversely as the distance between two successive nodes. One essential difference is that the ends of a stretched string must be nodes, whereas in pipes one or both ends may be *loops*, where the velocities experience their maximum change and the pressure is invariable. In the open organ-pipe both ends are loops, between which one node at least must exist if a sound is produced. This gives the fundamental vibration, and may be diagrammatically indicated, as in fig. 4, a . The wave-length is (approximately) double the length of the tube. The second harmonic is produced when two nodes intervene, as in b (fig. 4); the third when three nodes intervene, as in c (fig. 4); and so on. The wave-lengths of these are respectively the length of the tube and two-thirds the length of the tube. Hence, if the fundamental tone has frequency 100, the second has frequency 200, the third 300, and so on. In the closed or stopped organ-pipe, again, one end is a node and the other a loop. In fig. 5, a , we have a diagrammatic representation of the prime tone, whose wave-length is (approximately) four times the length of the tube. Thus by

Fig. 4.

simply stopping the one end of an open organ-pipe we lower the prime tone a whole octave. The next possible mode of vibration is indicated in *b* (fig. 5), in which are two nodes. Here the wave-length is $1\frac{1}{2}$ times the length of the tube. In the next mode, with three nodes (fig. 5, *c*), the wave-length is $\frac{2}{3}$ of the length of the

Fig. 5.

tube; and so on to higher harmonics. If the fundamental tone of a closed pipe has frequency 100, the next possible harmonic will have frequency 300, the next 500, and so on. Thus in any note uttered by an open pipe all the harmonics may enter; but in a closed organ-pipe only those of odd number can be present. This lack of the even harmonics gives a curious nasal quality to the tone of the closed organ-pipe. By overblowing we may so accentuate the second harmonic in the open pipe as to make it sound a note appreciably an octave higher than the fundamental note. By overblowing the closed pipe the pitch of the note jumps up an octave and a fifth. With flutes and whistles similar effects may be produced.

A tuning-fork is a vibrating bar whose one end is a node. In producing its fundamental tone each prong vibrates so that there is no other node, as in fig. 6, *a*. The next possible mode of vibration is when a second node exists, as shown in fig. 6, *b*. This first overtone is not related to the fundamental tone according to the harmonic series already given for strings and air columns.

Fig. 6.

For example, if the fundamental tone of the tuning-fork is C of the bass clef, the first overtone is two octaves and 7-7736 mean semitones higher—i.e. a little flatter than G $\frac{1}{2}$ above the treble C. In the case of stretched membranes, vibrating plates, and bells similar complexities hold; and it is impossible to get from them overtones harmonically related to the fundamental tone and to one another. There is no

doubt, however, that the characteristic clang of a bell is due to the presence of these anharmonic overtones; and the art in bell-making is to prevent them having a pronounced discordant effect on the ear. By careful manipulation the first anharmonic overtone of a large-sized tuning-fork may be made to sound instead of the fundamental tone, and not infrequently it may be heard along with it. In this latter case it rapidly dies away, and the tuning-fork continues to utter a pure tone of the simplest harmonic type. When strings or columns of air are vibrating, the harmonic overtones may be picked out by the ear with tolerable ease after a little practice. Their presence may, however, be made evident to the most unmusical ear by the use of resonators.

The function of a resonator is to reinforce the intensity of a note produced by some vibrating body in its neighbourhood. The principle is made use of in all musical instruments. For instance, in the violin the greater part of the energy of vibration of the string does not pass directly to the air, but indirectly through the body of the violin, which vibrates with the string. The sounding-board of a piano plays the same rôle, being set into vibration by the impacts of the waves upon the terminal

fixed points of the strings. In these and similar cases a greater mass of air is influenced by the vibrations of the system, the energy originally given to the string is more quickly transferred to the air, and the result is increased intensity. The word resonator is, strictly speaking, applied to a body which resounds to one note only or to one of a definite harmonic series. If a tuning-fork be held in front of the lip of an organ-pipe, one of whose own harmonics has the same pitch as the note of the tuning-fork, the sound uttered by the tuning-fork will be distinctly reinforced. This reinforcement will not occur in the case of a tuning-fork having no harmonic relation to the pipe. The pipe in the above case acts as a resonator. Again, hold down any note on the piano so as to leave the corresponding strings free, and then strike the note an octave lower, or an octave and a fifth, or two octaves lower. Release this latter note, so that its strings become damped, and the former note will be heard distinctly as if it had itself been struck. Its intensity may be reinforced again and again by repeated striking of a lower note of which it is an harmonic. Here the strings of the note that is being held down act as resonators to the corresponding harmonic of the note that is struck. The same effect may be produced by singing a suitable note, or playing it on some other instrument. The boxes to which large tuning-forks are attached are so shaped that the mass of air within them vibrates naturally to the note of the tuning-fork. And just as a pendulum or ordinary swing may be made to describe larger and larger arcs by properly timed impulses, so a resonator responds to the timed pulses of the note to which it is tuned. Helmholtz's spherical resonators, tuned to the successive harmonics of a particular note, are an indispensable part of the equipment of a physical laboratory. Each is a hollow sphere provided with two apertures diametrically opposite each other. The smaller aperture is made in the form of a small projecting tube which can be fitted close into the ear. Through the other and larger aperture the outside disturbance sets the mass of air inside the sphere into vibration. As an example of their use, take the case when the note to which one of the resonators is tuned is sounded by (1) an open organ-pipe, (2) a closed organ-pipe. By placing in turn each resonator to the ear we readily convince ourselves that the successive harmonics are all present in the sound of the open organ-pipe, but that with the closed pipe the even harmonics are absent. When the proper resonator is placed behind a tuning-fork the sound becomes powerfully reinforced. By taking advantage of this principle Helmholtz proved synthetically that vowel-sounds of the same pitch have different harmonics present. By means of the Phonograph (q.v.) Jenkin and Ewing analysed the vibrations produced by vowel-sounds at various pitches; and their results show that the relative intensities of the principal harmonics present in any given vowel-sound vary with the pitch.

As with all forms of wave-motion, sound may be reflected (see ECHO) and refracted. When a string or air-column is thrown into a steady state of vibration with nodes occurring at regular intervals there is in reality a reflected wave, which, travelling backwards along the vibrating substance, interferes with the forward-travelling wave in the manner already described. Interference (q.v.) is also shown by the phenomenon of beats.

The existence of beats is determined by the coexistence of two notes differing very slightly in pitch; and the number of beats per second is simply the difference of the frequencies. Because of the absence of upper harmonics in the note given

by a tuning-fork, the phenomenon is produced in its purest form by means of two tuning-forks originally in unison but thrown slightly out of tune by weighting the one tuning-fork with a small piece of wax attached to it. If the tuning-forks, for example, have frequencies 300 and 302, there will be heard two beats per second—i.e. the intensity of the resultant sound will vary from zero to a maximum and back to zero again twice every second. The reason of this will be easily seen if we consider the resultant effect of the two sets of waves at different times. For, since the two sounds have the same velocity, it is clear that across any surface set in the path of the rays of sound the higher note will transmit two more waves per second than the lower note, or one more wave in half a second, or half a wave extra in a quarter of a second. Suppose that at the beginning of the second chosen the nearly equal waves combine crest to crest and trough to trough, so as to produce an increased intensity; then a quarter of a second later the slightly quicker vibration will have gained half a wave-length on the other, crest will fall with trough and trough with crest, and little or no vibratory motion will be the result. At the half second, crest and crest will again coincide, and the resultant sound once more reach a maximum; and so on indefinitely. The transition from maximum to minimum loudness is of course gradual. If notes in which higher harmonics exist are used the beating is not so simple. For example, with open organ-pipes tuned to frequencies 300 and 302, not only will the primes beat twice a second, but the second harmonics 600 and 604 will beat four times a second, the third harmonics six times a second, and so on. There is generally no difficulty getting beats from a piano-forte note, since the two or three strings that belong to the note are rarely in accurate tune.

In general if m and n are the vibration numbers of two notes sounding together which give beats, $(m - n)$ will be the number of beats per second. If this beating does not occur oftener than two or three times a second the ear is not distressed. Rapid beating, however, produces very unpleasant sensations even after it has reached a rapidity too high to be counted. When the difference of frequencies $(m - n)$ is greater than 25 or 30, the note of frequency $(m - n)$ is heard in addition to the two original notes. There is no difficulty in hearing this differential tone, as it is called, when the two notes are sufficiently loud. On instruments giving sustained sounds, such as the organ, harmonium, and concertina, very marked differential tones are produced; and to an ear trained to their perception they are recognisable on the piano. When the difference of the frequencies lies between 30 and 100 the rattling of the beats may often be distinguished from the low hum of the differential tone; so that we are not warranted in regarding these two phenomena as of the same nature. By bringing the two notes by different courses to the two ears we can hear the beats but cannot hear the differential tone. Moreover, in addition to the differential tone $(m - n)$, there are other differential tones of frequencies $(2m - n)$, $(m - 2n)$, &c., and also at times a weak summational tone of frequency $(m + n)$. This last-named tone was discovered by Von Helmholtz, to whom we owe the complete discussion of the origin and significance of these Combinational Tones, as they are collectively termed. Two kinds are distinguished by him. If the vibrations transferred from the vibrating body to the air are very large the simple law of superposition may not hold. A simple pendular vibration, such as a tuning-fork may give, will when transferred to the air lose to some extent its simple harmonic char-

acter, and higher harmonics will enter in. If two simple pendular vibrations act powerfully on the air combinational tones will be produced in addition to the higher harmonics of the two original notes. These combinational tones existing in the powerfully disturbed air can be reinforced by use of resonators. Combinational tones of the second kind cannot be so reinforced, since they are produced in the ear itself. They are due to the asymmetric character of the drum of the ear, which cannot respond to two coexisting vibrations without producing combinational tones. The frequencies of these combinational tones, whether of the first or second kind, are all included under the general formula $Mm \mp Nn$, where m and n are the frequencies of the original notes, and M and N are integers from zero upwards. As experiment shows, only the first few integers are of any importance, and no summational tone of higher order than $m + n$ (M and N both unity) has ever been heard. As an example, take two notes having frequencies 200 and 315. Their principal combinational tones will have frequencies 115 ($315 - 200$) and 85 ($2 \times 200 - 315$). This latter may be regarded as the differential tone between the lower prime and the first combinational tone. These two tones can both be heard if the intensities of the sounds are sufficiently strong. Both theory and experiment show that the comparative intensity of combinational tones grows rapidly as the intensities of the real notes are increased, and also that combinational tones of low pitch are most prominent.

As first brought out clearly by Helmholtz, combinational tones are of peculiar interest when the two notes form a consonant interval. Thus, take any two notes a musical fourth apart. Their vibration numbers may be represented by $3n$ and $4n$. Their principal differential tone will have the frequency n ($= 4n - 3n$), and will therefore form the fundamental tone of which the given two are harmonic overtones. Again, take any perfect triad (*do, mi, sol*) having frequencies $4n$, $5n$, $6n$. Each successive pair gives the same differential tone n ; the first and last together give the differential tone $2n$. Thus we hear the low tone which is harmonically fundamental to all, and its octave. In some cases the differential tone becomes so loud that the real notes which are being sounded become merged in it as upper harmonics. If the notes of the triad are not in perfect tune the differential tones will not be harmonically related. On an organ tuned in equal Temperament (q.v.) the chord built upon the treble C consists of notes having frequencies 522, 657.7, 782.1 (see PITCH). The two lowest differential tones have frequencies 135.7 and 124.4—notes which, sounding together, produce 11.3 beats per second. The ear that has accustomed itself to the pure harmony of the perfect triad will easily recognise a certain dissonance in the triads given by pianos and organs.

Beats always mean the coexistence of two notes of nearly the same frequency. If on any organ or harmonium any note and its fifth are struck together beats are heard. It is indeed by getting rid of these beats that we finally effect a perfect tuning of say two contiguous violin-strings. These beats on the tempered instruments are due to the fact that the interval is not a true fifth, so that the higher harmonics which are present cause beating combinations. This is shown by comparing the first three harmonics of notes which form (1) a perfect fifth and (2) a tempered fifth.

PERFECT FIFTH.			TEMPERED FIFTH.		
C.	G.	Beats.	C	G	Beats.
522	783	..	522	782.1	..
1044	1044
1566	1566	0	1566	1564.2	1.8
&c.	&c.	..	&c.	&c.	..

Similar results may easily be obtained for all tempered intervals, if the higher harmonics exist in sufficient strength. We may, however, make use of the combinational tones in producing beats. For instance, by the rule given above, we get for the first combinational tones 260.1 and 261.9, which beat also 1.8 times a second. The second combinational tone is intensified by the actual presence of the second harmonic of C; and we can make the beating still stronger by sounding the octave along with C and G.

All vibrations in air of sufficient intensity and suitable frequency produce sound-sensations. The highest frequency which gives an audible sound is about 70,000. This is much higher in pitch than the highest notes used in music. For example, the frequency of the highest note on the pianoforte falls short of 4000. Very high pitched sounds near the limit of audibility are very disagreeable to the ear; and sounds which are heard by one person may be, because of their high pitch, quite inaudible to another. There are many noises of whose pitch it is impossible to say anything definite. They are no doubt confused mixtures of tones of fluctuating pitch. According to König the peculiar quality or timbre of trumpet notes and other notes of piercing quality is in great measure due to a fluctuating character in the vibration. The various overtones, both harmonic and anharmonic, do not combine with the prime in a steady periodic manner. Anharmonic overtones must of necessity produce fluctuations in the periodic character of the note; and the theory of quality cannot be complete without taking their existence into account. In this direction Helmholtz's theory requires extension.

Of great value and interest are Helmholtz's investigations on the forms of vibration of strings, especially of violin strings. If we can experimentally determine the form of the wave into which the string is thrown when bowed, we can by Fourier's mathematical process calculate the harmonics that enter in. Helmholtz solved the problem by viewing through a microscope the motion of a small white speck at different points of the string, the microscope itself being attached to the vibrating end of a tuning-fork, and being so made to execute a simple harmonic motion at right angles to the direction of vibration of the white speck. The principle of the method is identical with that introduced by Lissajoux in obtaining what are known as Lissajoux's Figures. Two tuning-forks, with bright reflecting surfaces fixed to their vibrating ends, are arranged so that while one vibrates to and fro vertically, the other vibrates to and fro horizontally. A beam of light is reflected from the one upon the other, and after a second reflection is focussed sharply upon a screen or viewed in a telescope. When either fork is vibrating alone the image on the screen will vibrate also along a straight line. But when both are vibrating together the light spot on the screen will execute the motion which is the resultant of the two mutually perpendicular vibrations. Definite figures are obtained only when the two forks are tuned accurately in unison, or by some simple interval apart. For example, if the two forks give the same note the figure on the screen will be an ellipse or one of its extreme forms, the circle or straight line. If the forks are *very slightly* out of tune—imperceptibly so to the ear—the ellipse will gradually change shape, passing from the circle to the straight line. The figures obtained when the ratio of the frequencies is as 1 : 2 (the octave), 2 : 3 (the fifth), 3 : 4 (the fourth), and so on, are very beautiful; and if the interval is just short of perfect tuning the gradual passing of the figure through a series of related but slightly differing forms is very in-

structive. The experiment is valuable as giving an optical demonstration of the laws of combination of vibratory motions in lines inclined to one another. Compare the explanation of elliptic and circular Polarisation (q.v.) of light.

Although sounds come to our ear through the air or other fluid as waves of compression and rarefaction, they may have their origin in vibrations of quite a different type. In solid substances there are distortional waves as well as compressional waves. In a pure distortional wave the substance changes form and does not change bulk. Its existence depends upon the Rigidity (q.v.) of the substance. In gases and liquids only compressional waves can exist, and these depend upon the compressibility (see COMPRESSION). When a bar, stretched string, or plate is set into vibrations a certain kind of elasticity is brought into play, and a certain strain produced, which in general involves both change of form and change of bulk. Corresponding to this there is an appropriate stress whose ratio to the strain is the coefficient or modulus of elasticity upon which the velocity of the wave depends. Calling this modulus E , we find for the velocity of a vibratory wave the expression $V = \sqrt{E/D}$, where D is the density of the substance set into vibration.

This formula was first applied by Newton to the case of air. Assuming Boyle's Law (see GAS AND GASES), he obtained the expression $\sqrt{P/D}$ for the velocity of sound, where P is the pressure. But when the proper numbers are put in the velocity is found to fall short of its true value by about 180 feet per second, or by one-sixth of the whole. Newton's assumption is in fact false. Boyle's Law holds only when, throughout the changes of pressure and density, the temperature remains constant. But in the rapid condensations and rarefactions which accompany audible sounds the temperature varies, increasing during condensation and decreasing during rarefaction. Now rise of temperature means increase of pressure and fall of temperature decrease; so that the result of these temperature changes is to increase the forces at work—i.e. to increase the elasticity. Laplace first made this necessary correction to Newton's calculation. We must in fact multiply the pressure by 1.41, which is the square of 1.2 nearly. The complete theory gives for the velocity of sound in dry air at a temperature of t° F. the value

$$V = 1122 + 1.09(t - 60) \text{ feet per sec.},$$

which is as near as may be to the mean of experimentally determined values.

The quantity E is the same for all the true gases. Hence the velocity of sound in gases varies inversely as the square root of the density. In other words, a given wave-length will vibrate proportionately faster. Thus, if an organ-pipe be blown with hydrogen gas in it instead of air, the note will leap up nearly two octaves in pitch, since the density of air is 14.4 times that of hydrogen.

In the case of any liquid the quantity E is the reciprocal of the compressibility, which is not appreciably affected by slight changes of temperature. For water the density is unity, and E is 2.08×10^{10} . Hence $V = 144,000$ centimetres (4730 feet) per second. Colladon's value, determined by experiments on the Lake of Geneva, was 143,500. Thus sound travels four times faster in water than in air. In the case of solids, in the form of thin rods or wires, waves of compression will travel at still higher speeds. The quantity E is practically Young's modulus of elasticity. In steel $E = 2.14 \times 10^{12}$, and $D = 7.85$; hence $V = 522,000$ centimetres (17,130 feet) per second, or nearly sixteen times the velocity of sound in air.

The standard book on Sound is Lord Rayleigh's *Theory of Sound* (1878; 2d ed. 1894). Tyndall's *Sound* is a popular exposition of the subject, illustrated by well-chosen experiments. Helmholtz's *Tonempfindungen*, or *Sensations of Tone* (Eng. trans. 1875; 4th ed. 1912), discusses in a highly original manner the borderland between sound as a branch of physics and music as a branch of æsthetics. Sedley Taylor's *Sound and Music* (1873; 3d ed. 1896) is a simple exposition of the chief of Helmholtz's discoveries. König's *Expériences d'Acoustique* (1889) contains some valuable novelties. Lamb's *Dynamical Theory of Sound* (1910) is introductory to the study of Rayleigh and of Helmholtz. And useful text-books are those of Catchpool (1894; 5th ed. 1922), Barton (1908; 2d ed. 1919), Capstick (1913; 2d ed. 1922). See *Nature*, vol. xliii. 1890; also the articles ACOUSTICS, HARMONICS, MICROPHONE, TELEPHONE, VOICE.

Sound (O.E. and Ger. *Sund*), the strait which leads from the Kattegat into the Baltic Sea, having Sweden on the east and the Danish island of Sjælland on the west. It forms the usual passage from the North Sea to the Baltic, is 50 miles long and nearly 3 miles wide at its narrowest part, between the towns of Helsingborg and Elsinore. Its passage, defended by the strong Danish castle and fortress of Kronborg, was forced by Nelson in 1801 (see COPENHAGEN). From the 15th century all ships using this channel, except such as belonged to certain of the Hanseatic towns and one or two others in the Baltic, were charged toll for passing through. These Sound Dues were abolished on 14th March 1857 by a treaty between Denmark and the principal maritime powers. A pecuniary compensation of £3,386,260, of which Great Britain paid £1,125,206, was given to Denmark, which bound itself to maintain the lighthouses and superintend the pilotage of the Sound.

Sound, in fishes. See AIR-BLADDER.

Sounding. From the earliest times navigators have ascertained the depth of the sea in shallow waters by means of a hand-lead. This consists of a hempen rope, marked off into fathoms by worsted of different colours, to which is attached a leaden weight armed with tallow or having a valved cavity to bring up a sample of the deposit at the sea-bottom. In addition to the hand-line steamers are now often furnished with a machine to ascertain the depth while under way. This consists of a winch, wire rope, fair-lead, and a sinker provided with a glass tube, which, on being removed after a sounding, indicates by the action of sea-water on a chemical coating the hydrostatic pressure on the air in the tube and consequently the greatest depth reached by the sinker. One of the latest inventions to ascertain the depth of water while a ship is in motion is the 'submarine sentry.' This is a kind of submarine kite, which is trawled after the ship at a depth of 25 or even 40 fathoms, and as soon as the kite strikes the bottom the fact is indicated in the chart-room. Very many attempts were made to sound the deep sea before satisfactory results were obtained. Magellan during the first voyage round the world attempted to sound the open ocean in the Pacific. Not having reached bottom in 200 fathoms he naïvely concluded that he had crossed the deepest part of the ocean. Ellis in 1749 and Mulgrave in 1773 failed to sound the deep sea. Sir John Ross was more successful, for in 1818 he sounded in the Arctic seas in 1050 fathoms, bringing up a specimen of the bottom. Sir James Ross during his Antarctic expedition sounded in 2425 fathoms, and on two occasions no bottom was found with 4000 fathoms of line. There was a great uncertainty about these depths owing to there being no sure indication when the weight reached the bottom. Brooke, an officer of the United States navy, in 1854 gave a great impulse to deep-sea sounding by introducing a detaching

weight, the sinker being left at the bottom, and only a small tube with a sample of the bottom being hauled up with the line. A modification of this apparatus was used during the *Challenger* expedition, 3 or 4 cwt. of iron sinkers being left at the bottom in each sounding. A sudden decrease in the rate at which the rope was running out showed when the sinkers had struck the bottom. The sounding line was $\frac{3}{4}$ inch in circumference, and in addition to the sinkers and sounding tube there were attached to it several thermometers, a water-bottle, piezometers, and other instruments. Deep-sea sounding for telegraphic purposes is now carried on by means of wire rope, or steel wire, such as that used for the 'strings' of pianos: this was introduced by Sir William Thomson (Lord Kelvin). The friction of the wire in passing through the water is much less than that of the hemp rope. It runs out and can be hauled in much more rapidly; a smaller sinker can be used, and this often can be pulled up along with the wire. When only the depth is required a fine twine, or a wire, with a weight is now used in sounding in deep water, the whole being cut adrift when the depth is ascertained. The time employed in hauling in the line is thus saved, which well repays the loss of twine and weight. Quite recently very rapid soundings have been made by utilising the knowledge of the velocity of sound-waves in sea-water. An apparatus fixed outside the hull of the ship makes a small explosion. The sound-wave thus generated is reflected back from the sea-bottom as an 'echo,' and the time required for the double journey is observed instrumentally. From this time the depth is deduced. The deepest soundings and results are noted at SEA, PACIFIC OCEAN, &c.

See *Narrative of the Cruise of H.M.S. Challenger*, vol. i.; *Deep-sea Sounding and Dredging*, by Sigbee; and *Challenger Report on Deep-sea Deposits*, by Murray and Renard.

Soup. As a general rule a soup is made by boiling meat or vegetables in what is called 'stock.' To prepare the latter the cook obtains fresh meat, bones, and vegetables such as carrots or leeks, and after the addition of salt allows them to simmer for some hours in sufficient water. The stock is the infusion thus prepared, and contains small quantities of starch, if vegetables have been used, and in any case some gelatine, which will often cause it to solidify on cooling. Together with a small quantity of nourishment, the infusion has extracted from the meat and vegetables those pleasant flavoured extractives which give it taste. Taking this stock as a basis, the various soups are made by boiling with it the bones and flesh of the hare, ox-tails, &c., and vegetables such as carrots, potatoes, turnips, rice, sago, &c.

If we view the preparation of soups from the point of domestic economy, the following facts must be kept in mind. Bones, otherwise valueless to the householder, contain much nutritive gelatine, which is extracted from them in the preparation of stock; no bones should therefore be thrown away, for their use is a clear gain. It is to be remembered that meat on the other hand yields little of its nutritive matter to the stock, and if the meat be thrown away, as it generally is in England, the greater part of its value is lost. It is the greatest waste of nutritive material to prepare a stock from gravy beef, which yields hardly more to the water than its flavouring extractives; yet householders regularly buy meat for this wasteful purpose. If then it is an object to obtain the nutritive value from the food, the meat should as much as possible be retained and eaten. While the greatest extravagances may be thus committed by using meat, which might be eaten as such, in the

preparation of stocks and clear soups, it is certainly the case that equal waste is frequently committed by throwing away the water in which meat, fowls, fish, bacon, and pork have been boiled. This always contains some nutritive matter, and every capable cook should be able to make it the basis of an excellent soup. As to clear soups and Beef-tea (q.v.), numberless invalids are yearly starved out of existence by doctors and nurses, who imagine that by stewing a pound of gravy beef the nourishment goes to the water. Soups thickened by vegetables such as peas, potatoes, &c., are highly nutritious.

South, ROBERT, born at Hackney in 1633, from Westminster passed as a student to Christ Church, Oxford, in 1651. In 1658 he received orders from a deprived bishop, and in 1660 was appointed public orator. His vigorous sermons, full of mockery of the Puritans, delighted the restored royalists; and he became domestic chaplain to Clarendon, prebendary of Westminster in 1633, canon of Christ Church in 1670, rector of Islip in 1678. He 'acquiesced in' the Revolution, but blazed out against the proposed scheme of Comprehension. In 1693 began, with his anonymously published *Animadversions*, his great controversy with Sherlock, Dean of St Paul's, who had defended the Trinity against the Socinians. Sherlock published a *Defence*, to which South rejoined in his *Trithæism charged upon Dr Sherlock*. Before his death (8th July 1716) South is said to have refused the see of Rochester and deanery of Westminster (1713). His sermons are masterpieces of clear thought expressed in vigorous English, sometimes rising to splendid eloquence, and often seasoned with wit and sarcasm. He abhorred mysticism and extravagance, sneers at the new philosophy, and carried to a height unusual even among royalists the fatal Stuart theories of passive obedience and the divine right of kings.

His sermons fill 11 vols. (1692-1744); in 1717 appeared his *Posthumous Works*, with Memoir; also his *Opera Posthuma Latina* (all republished in 1823). See Deart Lake in *Classic Preachers* (1877).

South Africa, geographically, is that portion of the African continent south of latitude 15° S., i.e. south of a line drawn from Mossamedes in Portuguese West Africa to Mozambique in Portuguese East Africa. Politically, the term is applied to Africa south of the Zambezi, a broad tongue-shaped territory (roughly, 1200 miles long, and 1600 miles wide at its base), now entirely under the British flag, save the southern half of Portuguese East Africa.

British South Africa comprises:

	Area (sq m)	Pop. (1921)
Union of South Africa	472,347	6,928,580
South-West Africa	322,450	227,739
Basutoland	11,716	498,781
Bechuanaland Protectorate	275,000	152,983
Swaziland	6,678	106,961
Southern Rhodesia	149,000	899,187
British South Africa	1,237,191	8,814,281

The physical features and geological structure of the subcontinent are described in the articles on its component parts and on Africa. The coast-line describes a parabola, has few bays and indentations, and no islands of any size. The only big rivers are the Zambezi and the Limpopo, flowing east, the Orange River flowing west. There are no lakes, except Ngami and 'pans' of varying size. Forests are few. The whole of British South Africa, apart from a very narrow coastal belt, is over 600 feet above sea-level, the great mass of the interior consisting of plateau from 3000 to 6000 feet in elevation, behind an arc of mountain ranges that attain a maximum of 11,000 feet in the Drakensbergs.

Over so huge an area climate naturally varies, but the entire country abounds in bright sunshine, the average rainfall is low (c. 19 inches per annum for the Union), and most parts are well adapted for Europeans, being much more temperate than other lands of like latitudes. The summer coincides with the European winter. The official time of South Africa is two hours in advance of Greenwich time. Sparsely populated, the subcontinent has few large towns and has several vast desert areas (notably the Kalahari and the Namib in South-West Africa).

THE UNION OF SOUTH AFRICA (*Unie van Zuid Afrika*, or *Suidafrika*, to use the Afrikaans form) was formed in 1910 of four original provinces—Cape of Good Hope, Natal, Transvaal, and Orange Free State; and, as a mandatory of the League of Nations, administrators (since 1920) South-West Africa. The area and population of the Union and its provinces at the 1921 census are given in the following table:

	Area (sq m)	White Pop.	Total Pop.	Total, 1911
Cape of Good Hope.....	276,966	650,609	2,782,719	2,564,965
Natal	35,284	136,838	1,429,398	1,194,043
Transvaal.....	110,450	543,485	2,087,636	1,686,212
Orange Free State.....	49,647	188,556	628,327	528,174
Union of South Africa	472,347	1,519,488	6,928,580	5,973,394

The Union is nearly four times the size of the British Isles, about one-eighth the size of Canada, and one-sixth the size of Australia. There are 14·67 persons (3·22 white) to the square mile in the Union, as compared with 11·61 in New Zealand, 2·36 in Canada, and 1·82 in Australia. Of the white (or 'European') population over 55 per cent. live in urban areas. The twelve largest towns—Johannesburg, Cape Town, Durban, Pretoria, Port Elizabeth, East London, Bloemfontein, Kimberley, Pietermaritzburg, Germiston, Benoni, Krugersdorp—together account for one-third of the white population. Pretoria is the seat of government, Cape Town the seat of the legislature—inter-colonial jealousies having ruled out a single capital city. Five out of six European inhabitants are South-African-born (Africans). Males still outnumber females in the Union among both Europeans (782,035 to 737,453) and non-Europeans (2,754,957 to 2,654,125); but each year reduces the margin in the case of whites. The birth-rate among Europeans, though falling (31·11 in 1911-15; 28·56 in 1916-20; barely 27 in 1921-25), is higher than in the United Kingdom or the other dominions. The death-rate (European), under 10 in 1921-25, is below that of Europe and America, but slightly higher than in New Zealand and Australia. The natural increase of white population by excess of births over deaths averaged 26,000 per annum in 1911-25. Immigration is slow and fitful. More than half the European inhabitants belong to the Dutch Reformed Church; the Anglican, Wesleyan Methodist, Presbyterian, Jewish, and Roman Catholic churches come next in order. While the European population within the Union increased by only 400,000 between 1904 and 1921, that of the non-Europeans was augmented by 1,350,000. Of 5,409,092 non-Europeans enumerated at the 1921 census, 4,697,813 were natives (Bantu), 165,731 Asiatics (Indians, and a few Chinese), and 545,548 of mixed and other non-European race (half-castes, Cape Malays, &c.; all save 60,000 of these live in the Cape).

Constitution.—The Union of South Africa (as established by the South Africa Act, 1909, of the British Parliament) is a legislative Union with a written constitution of a flexible type, though certain of its provisions—such as equal language rights and the Cape native franchise—are specially

safeguarded, and can be amended or repealed only by exceptional procedure. South Africa deliberately chose a much closer form of union than that adopted by Canada, Australia, or the United States of America. Rejecting federation as a half-measure, likely to perpetuate rather than cure its peculiar internal troubles, South Africa preferred a highly centralised type of government. The legislatures of the four colonies were completely swept away, and one national parliament took their place. Four Provincial Councils were set up—at Cape Town, Pretoria, Maritzburg, and Bloemfontein—but these have nothing like the powers of the provincial councils of Canada, much less those of the state legislatures in Australia; their control is confined to purely local affairs (such as roads and bridges, hospitals, municipal institutions), primary and secondary education, their most important charge, being only temporarily entrusted to them.

Parliament consists of two houses—a Senate and a House of Assembly. The Senate is constituted normally for ten years, and numbers 40 members (who must be white, and aged not less than thirty); of these eight are nominated by the governor-general in council (four for special experience of native affairs) and eight elected by each of the four provinces, the electors being the members of the House of Assembly and provincial councillors for the province in question sitting together and voting according to the system of proportional representation (with the single transferable vote). In money matters the Senate is subordinate to the House of Assembly. This, at the 1924 election, contained 135 members (M.H.A.'s)—51 for the Cape, 17 Natal, 17 Orange Free State, and 50 for the Transvaal, which alone since 1910 has added to its representation (originally 36) in virtue of its increased European male adult population. The maximum membership provided for is 150, and no diminution of any province's representation is permitted till that total is reached. The maximum duration of each House of Assembly is five years. M.H.A.'s must be white. Each electoral division returns only one member. Manhood suffrage obtains in the Transvaal (141,000 registered voters in 1921) and O.F.S. (49,000), but voters must be of European descent. In the Cape and Natal males over twenty-one fulfilling certain easy property or income qualifications have a vote; there is no colour bar for the franchise in the Cape (41,000 non-Europeans out of 197,000 voters in 1921); and in Natal a few non-Europeans (400 out of 34,000 voters) are enfranchised. Women have no parliamentary vote as yet in South Africa. A joint sitting may be convened in the event of a deadlock between Senate and House of Assembly, and must be held to pass measures affecting certain clauses of the constitution. A majority consisting of not less than two-thirds of the total number of members of both houses is necessary to disqualify, on the ground of race or colour only, claimants for the franchise in the Cape; and in any case names of those already on the register may not be removed on solely colour grounds.

The executive government is administered by a governor-general, who represents the king and acts on the advice of the governor-general in council (the Union ministry). Ministers in charge of departments of state may not exceed eleven in number. The governor-general is commander-in-chief. He is also High Commissioner for the native territories outside the Union; subject to the imperial government, as such he is Governor of Basutoland, supervises the affairs of the Bechuanaland Protectorate and Swaziland, and has certain powers of control regarding native administration in Rhodesia. The Union is represented in the United Kingdom by a High Commissioner of its own.

Provincial Administration.—In each province, as chief executive officer, is an Administrator, appointed by the governor-general in council for five years. He acts as chairman of an executive committee of four persons, which carries on the administration of provincial affairs on behalf of the provincial council. These councils are elected (actually on party grounds) for three years by the parliamentary voters within the province; they pass ordinances dealing with matters under their control; and elect executive committee members by a system of proportional representation (with single transferable vote). To the Cape provincial council non-Europeans may be—and have been—elected. Provincial expenditure—of which education absorbs three-fourths—is met partly by provincial taxation (transfer duty; liquor, motor, and other licences; taxes on betting and entertainments; Cape property tax and companies tax; O.F.S. education tax; Transvaal poll-tax, employers' tax, and native pass fees, &c.), partly by a Union government subsidy and, in the case of Natal and the O.F.S., a special Union grant of £100,000.

Law is based on the Roman-Dutch system of jurisprudence. There is a Union ministry of justice and each province has an attorney-general. The supreme court of South Africa consists of an appellate division (with its seat in Bloemfontein: presided over by the chief-justice, it hears appeals also for Southern Rhodesia and South-West Africa), four provincial divisions, besides local divisions (Cape eastern districts; Griqualand West; Witwatersrand). Natal has a native high court. In every 'district' is a magistrate's court.

Defence.—Under the Defence Act of 1912 every white citizen, from seventeen to sixty, is liable to serve in South Africa in time of war, within or without the Union. Besides the permanent army (artillery, air service, &c.), there is the Citizen Force, consisting of (a) an active force, made up of volunteers undergoing peace training for four years—the ballot not yet having been needed; (b) citizen force reserve; (c) royal naval volunteer reserve; and (d) national reserve. In 1921 the Union Government took over the entire defence of South Africa; imperial troops were withdrawn; the Castle, Cape Town, was handed over to the nation; and the nucleus of a South African fleet formed. The naval headquarters are at Simonstown (q.v.); the military college is at Roberts Heights. The South African Police patrol the whole Union.

Education.—Higher (or university) education is controlled by the Union government; primary and secondary education by the respective provincial councils—until such time as the Union parliament decides to take these over. Meantime each province carries on its own school system, and uniformity has not been seriously attempted, although a central board of education to promote co-ordination was proposed in 1924. There are four universities in the Union—(1) University of Cape Town (till 1918 the South African College; richly endowed with Wernher-Beit bequests; boasting the biggest teaching staff and new buildings at Groote Schuur); (2) University of Stellenbosch (Victoria College till 1918; Dutch in atmosphere; specialising in agriculture, law, theology); (3) University of Witwatersrand (1922; once the South African School of Mines and Technology); (4) University of South Africa, an examining university, which superseded the University of the Cape of Good Hope in 1918, and has as constituent colleges (a) Grey University College, Bloemfontein; (b) Huguenot College, Wellington; (c) Natal University College, Maritzburg; (d) Rhodes University College, Grahamstown;

(e) Potchefstroom University College; (f) Transvaal University College, Pretoria. The South African Native College, founded at Fort Hare in 1914, was recognised as 'a place of higher education' in 1923, as were the Natal and Cape technical colleges.

The Union Observatory is near Johannesburg; the Royal Observatory (1820) at Cape Town is under admiralty control. The South African Public Library (1818) in Cape Town, a national institution, is the oldest and largest library in the Union. There are national zoological gardens at Pretoria and botanic gardens at Kirstenbosch, near Cape Town.

South African Literature is, like the nation, still in its infancy. Olive Schreiner (*Story of an African Farm*), Sir Percy Fitzpatrick (*Jock of the Bushveld*), and Roy Campbell (*The Flaming Terrapin*) are among the most noteworthy of those who have found inspiration in the land of their birth, as have Thomas Pringle and Lady Anne Barnard, Rudyard Kipling, and Rider Haggard—to mention no others—in their land of sojourn.

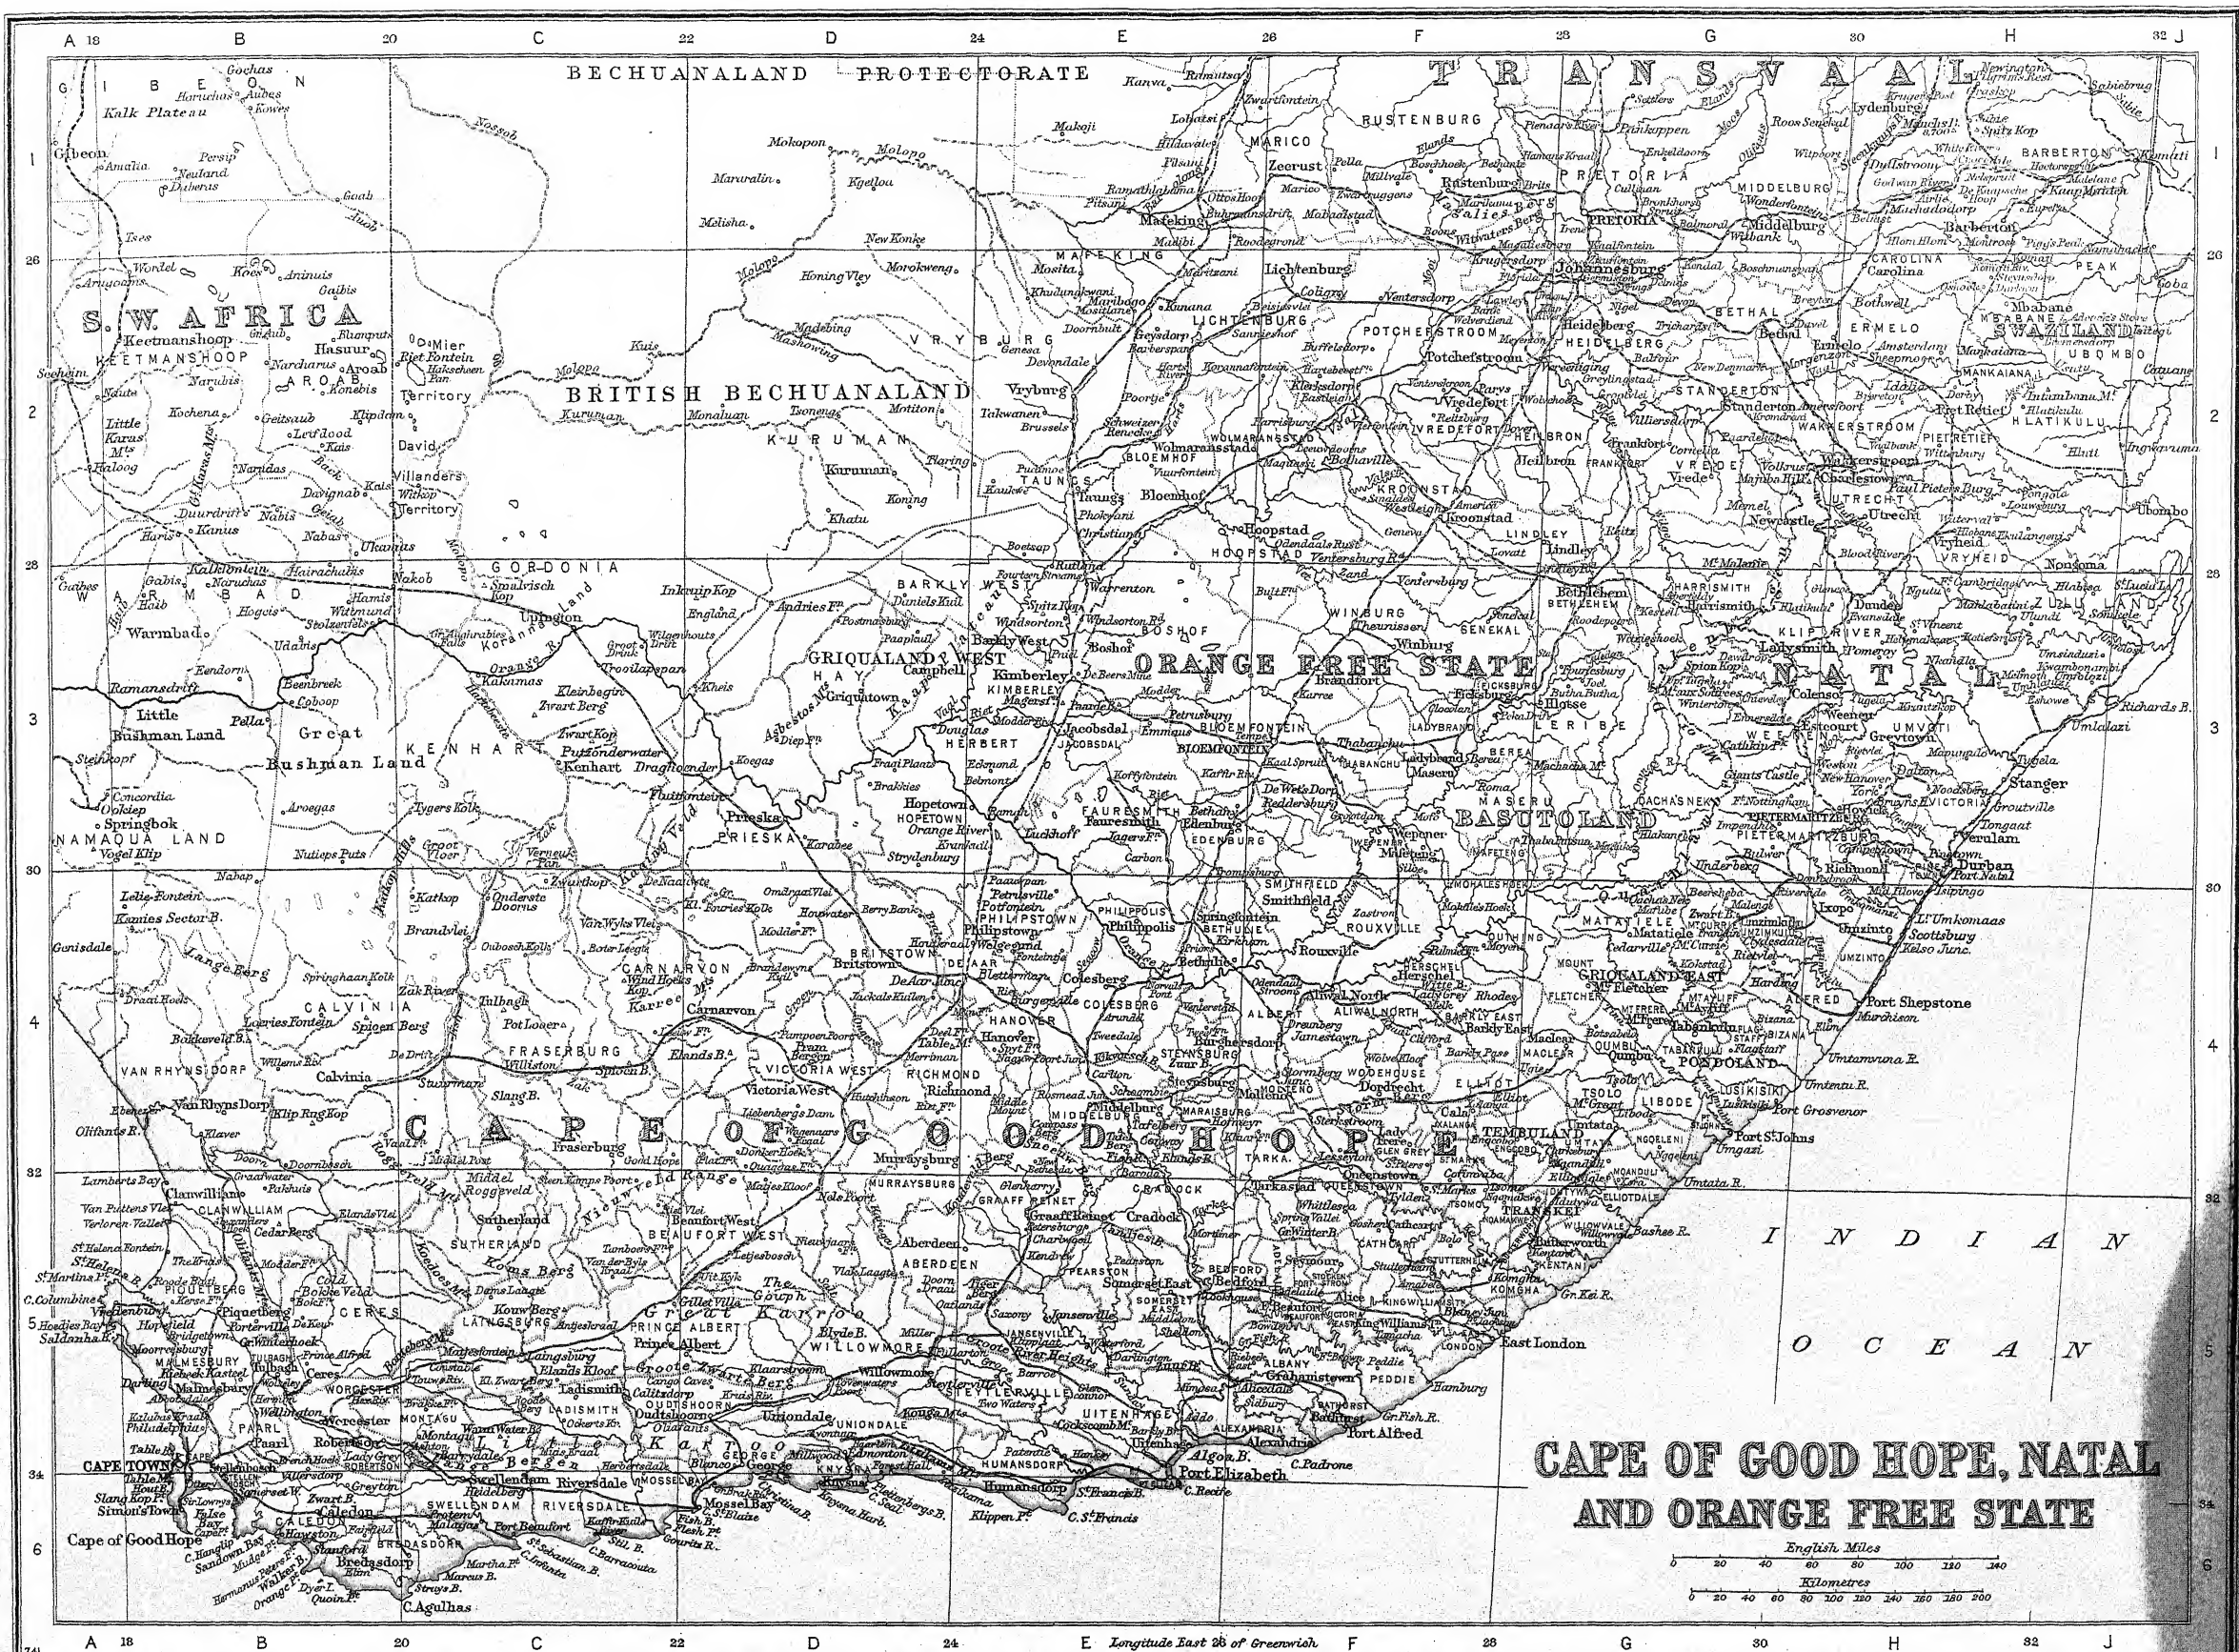

Languages.—The South African Act (§ 137) put English and Dutch on an equal footing as 'official languages of the Union.' Dutch includes Afrikaans. (This Cape Dutch—the Taal, i.e. 'the language'—is a highly expressive vernacular, and diverges not a little from High Dutch, having lost its inflexions and been affected in syntax, pronunciation, and vocabulary by long isolation from Holland and through contact with other races, white and coloured, in entirely different surroundings.) Both English and Dutch are used in parliament, in government publications, on postage-stamps, as mediums of instruction in schools, &c. For various reasons more Dutch speak English than conversely. Bilingualism is increasing. Fully half the European population now speak both languages (as against 42 per cent. in 1918). One-fourth speak only English, and rather less than a fourth only Dutch. It has been estimated that Dutch is to-day the mother tongue of about 60 per cent. of the white inhabitants of the Union. Many Afrianders can also speak 'kitchen Kaffir' or one of the common Bantu languages (Xosa, Zulu, Suto, &c.).

Racialism in South Africa is the clashing of the English-speaking and Dutch-speaking sections of the community. The Dutch outnumber and outvote the English, but the latter largely monopolise trade and commerce, finance (banking, insurance, &c.), and industry (mining and manufactures), the Dutch being mostly farmers (Boers). Natal is overwhelmingly English, Orange Free State equally Dutch; the Cape and Transvaal are more Dutch than English. The English congregate in the large towns; the Dutch are scattered throughout the country districts, in dorps and backveld. The Dutch cling to republican traditions, the English to imperial ties. Secessionism whets Jingoism and *vice versa*. The makers of the South African Union rose above racialism. Smuts dealt the 'two streams' policy a shrewd blow, but did not kill it, when he united the moderate Dutch and English in one political party. Rancorous racialism must die out if the white people of South Africa are to solve successfully the biggest problem of their country—the Native Question. Happily, *Eendracht maakt macht* ('Union is strength') is an old South African motto.

The Native Question overshadows all other problems in South Africa. The Europeans represent barely 22 per cent. of the total population of the Union, and only 18 per cent. of that of British South Africa. Out of every nine people in the Union six are black, two white, and one brown (Asiatic or of mixed race). Non-Europeans to-day outnumber Europeans by over four millions.

Between 1904 and 1921, while the European population of British South Africa added under half a million to its ranks, the non-Europeans added over two millions to theirs. Thanks to a high birth-rate and a low death-rate, and to immigration, the whites during the present century have just managed to maintain their relative proportion. But the birth-rate is falling and immigration is inconsiderable. Registration figures for non-Europeans are very incomplete; it is clear, however, that the native population, no longer depleted by tribal wars and famine, is multiplying as fast as the white population, and as time goes on, with improved conditions, is likely to increase still faster. South Africa is thus faced with a colossal colour problem such as confronts no other of the great Dominions, where the indigenous races form a tiffing minority and are in most cases dying out. The task of raising the black man is the 'white man's burden.' The coexistence of Kaffir kraals and modern cities, tribal leathendom and European civilisation, presents endless baffling difficulties; but the one phase of the native question which dwarfs all others at present is the labour problem. In South Africa all unskilled labour is classed as 'Kaffir work,' and every white man or woman is in a sense an aristocrat. In the kitchen, in the fields, in the mines, on roads and railways and where not, natives do the rough work from which whites are debarred by dignity or delicacy. Thus excluded from the domain of unskilled labour, domestic and industrial, by economic circumstances (native labour is much cheaper and more plentiful), if not by choice, Europeans are prone to claim for themselves a monopoly in skilled labour and non-manual work, and resent any invasion of what they consider their own field. Hence the Colour Bar—exclusion from certain employments on the ground of colour, regardless of fitness. A hard and fast horizontal line is drawn in this way in the labour market between whites on top and blacks beneath. But such a condition of things cannot be perpetuated: education is bound to qualify more and more natives for the professions, commerce, and higher categories of industry, for posts hitherto monopolised by whites. A policy of Segregation is now advocated by many Afrianders, whereby a vertical line, instead of a horizontal line, would separate the two races, and within certain allocated areas (some already in existence) the black South African would be free to work out his own social salvation under some form of native administration. Hence a growing demand that the native territories of Bechuanaland, Basutoland, and Swaziland, still under imperial administration, be transferred to the Union, as anticipated in the South Africa Act.

Asiatic Problem.—Numerous as are the natives of South Africa, it has been found necessary to import labourers for the mines and plantations—and thereby the colour tangle has been further complicated. The South African native does not willingly absent himself from home for more than six months at a time. The Transvaal mines employ over 200,000 natives, and half of these are now brought from Portuguese East Africa—Chinese labour having been tried and abandoned. Owing to the demands of the mines Cape farmers cry out at the scarcity of native labour. Natal sugar and tea planters solved their labour difficulty by introducing thousands of indentured coolies from India. And so arose the acrimonious Asiatic question, which the Union government inherited from the former Colonies, especially Natal and the Transvaal. The door was closed on further male Asiatic immigration by an Act of 1913. Of 164,000 Asiatics in the Union (1921), 142,000 live in Natal, where they outnumber the Europeans; over 100,000 of

them were born in South Africa. Indian traders, with their low scale of living, undersell European rivals. The Class Areas Bill, which was introduced in 1924, to establish separate trading and residential areas for Asiatics, together with a Natal Ordinance to abolish the limited municipal franchise of Indians, inflamed anew feelings never harmonious in view of the Indians' claim to equal rights with Europeans as citizens of the British Empire. This Asiatic question to-day, as in Gandhi's day, is a constant source of trouble between South Africa, the imperial authorities, and the government of India.

Mining—For half a century and more its mineral resources have shaped the history of South Africa. The discovery of, first, diamonds, then gold, saved the land from neglect and ruin. In fifty years South Africa produced gold and diamonds to the value of one thousand millions sterling. The mines made South Africa famed the world over; they brought it capital and population; they gave it railways, hastened development of the land, employed a quarter of a million men, bore the bulk of taxation, provided the lion's share of exports. But the blessing was not unmixed. The mines ensured prosperity but endangered peace, intensifying the enmity of Boer and Briton. South Africa is easily the world's chief gold-producer, alone supplying as much as all other countries combined. The Union produced 9,597,592 fine oz. of gold in 1925, valued at £40,767,981—a record. In 1868–1925 the Transvaal mines yielded gold to the extent of £870,000,000. Gold is a necessity, with a standard value and a steadily growing production; diamonds are a luxury, whose production has to be restricted and whose price is liable to sudden violent fluctuation. Of the world's diamond output South Africa (if we include South-West Africa, Belgian Congo, and Angola) has a virtual monopoly. In 1870–1925 the Union's diamond production totalled over £265,000,000. The major share came from the Cape (Kimberley mines; Griqualand West and other alluvial diggings); but the Transvaal (Premier mine), and O.F.S. (Jagersfontein) contribute large quantities of cheaper stones. The output for 1907 was a record for quantity, viz. 5,170,812 carats = £9,985,926; that of 1920 for value, viz. 2,545,017 carats = £14,762,899. The Union is fortunate in possessing coal in every province. The Cape coal-mines are poor, and now little worked. Natal coal is excellent, and supplies cargo and bunkers. The Transvaal mines are most productive and are handy for the Rand. The Union's total coal output exceeded 16 million tons in 1925. Other valuable mining industries are copper (Namaqualand and N. Transvaal), tin (Transvaal and Cape), silver (Transvaal), lead (Transvaal), salt, asbestos (Cape and Transvaal). Iron ores are little worked as yet. Platinum discoveries have been reported in the Transvaal, and may yet enhance the extraordinary mineral wealth of South Africa.

Manufactures.—Compared with mining and farming the manufacturing industries of South Africa are unimportant, though developing. The industrial census of 1923 recorded 170,000 employees (60,000 whites), working in 7000 factories. Farmers, foresters, and fishers produce raw materials—for wine-making (the pioneer industry of South Africa), jam and fruit preserving, flour-milling, brewing, butter and cheese making, tobacco factories, leather-working and tanning, weaving, cotton ginneries, soap and candle-making, sawmilling and wood-working, fish preserving, crayfish canning; dynamite factories supply the mines; engineering works supply the railways, &c. But, foodstuffs apart, South Africa still goes abroad for the great mass of the manufactured articles she requires.

Farming was the industry of South Africa before the mines were discovered, and, as these exhaust themselves, it must become more and more the mainstay of the country, manufacturing industries being thus backward and restricted. In the few years since Union, great strides have been made by the agricultural and pastoral industries. National administration makes it easier to combat drought and plagues, such as locusts, east coast fever, and scab; conservatism among farmers, thanks to official experts of every kind, is yielding to modern scientific methods; government inspection ensures higher grades and uniformity of exported produce; and South Africa now exports numbers of foodstuffs (e.g. meat, eggs) which she imported in the first years of Union. A large percentage of the white population and an overwhelming majority of the natives are 'on the land.'

First in introduction and foremost in importance is the breeding of woolled sheep (merinos). As a wool-producing country South Africa ranks fourth, Australia, Argentine, and U.S.A. alone exceeding her contribution. In 1921–25 the average annual export of wool totalled 200,000,000 lb. The Cape accounts for half this amount, the O.F.S. for one-third. The Union live-stock census in 1921 showed: woolled sheep, 27,757,000; other sheep, nearly 4,000,000; Angora goats, 2,284,000 (over 2,000,000 in the Cape alone—the world's chief mohair producer); other goats, 5,552,000; pigs, 914,000; ostriches, 262,000 (almost all in the Cape; half a million less than in 1913); horses, 920,000; mules, 116,000; asses, 722,000; cattle, 8,557,000 (5,000,000 more than in 1904). Cattle-breeding is progressing rapidly, types being improved for both dairy and beef purposes. The chief cattle areas are in the eastern Transvaal, O.F.S. highveld, Natal, and Cape east coast; the northern Transvaal has great potentialities for cattle ranching.

By far the most important grain crop of South Africa is maize (mealies), which thrives remarkably in the eastern half, and especially in a triangular zone in northern O.F.S. and southern Transvaal. Maize is the staple food of the natives, and has an unlimited market overseas. Production increased over tenfold between 1903 and 1923, when 4,000,000,000 lb. were recorded. Over 2,000,000,000 lb. of maize and maize meal were exported in 1925, valued at nearly £6,500,000. Maize takes fourth place among South African exports, after gold, wool, and diamonds. The export trade has been built up with amazing rapidity since the war of 1899–1902, before which South Africa could not supply her own maize requirements. Huge grain elevators have been erected at Durban and Cape Town, and smaller ones in the country. What wheat is to Canada, mealies are to South Africa. The Union provides its own oats, rye, and barley, but only 70 per cent. of its own wheat demands. These crops are grown chiefly in the south-west coastal region of the Cape. Kaffir corns (grain sorghums) flourish in areas unsuited to maize, and supply food, drink (Kaffir beer), and forage. The main forage crop is lucerne, grown especially in the Cape ostrich districts and other irrigated areas.

Climate and configuration combine to make South Africa an ideal fruit-growing country. The western Cape Province produces and exports delicious grapes, and makes wine and brandy, raisins and currants. Citrus fruits (oranges, naartjes, &c.) are more and more extensively grown in the Cape, Transvaal, and Natal, and are exported in ever-increasing quantities, as are pears, peaches, plums, pine-apples, and other fruits (fresh, dried, or canned). In 1925,

2,330,000 lb. of fruit were exported, valued at £714,000. Natal and Zululand have 200,000 acres of sugar plantations, and export what is not consumed in the Union. (In 1925, 600,000 tons of sugar, worth £767,000, were sent overseas.) Tobacco is grown in all the provinces, particularly the Transvaal and Cape. Tea is produced on the Natal coast. Cotton-growing is progressing in the Transvaal and Natal. Next to maize the principal product of the soil figuring in the export tables is wattle. Natal has some 300,000 acres of wattle plantations, and the export of bark and extract (for tanning) mounts rapidly.

Forests.—The Union is scantily timbered. Fire and the axe have played havoc with such forests as there were. Deforestation is a cause of desiccation, from which South Africa suffers. Indigenous forests cover 777,000 acres, chiefly along the south and east coasts (Knysna, Transkei, Natal). There are 6,700,000 acres of scrub or dwarf forest, and 558,000 acres of plantations—mostly wattles, gums, and conifers. Together these represent less than 3 per cent. of the whole country. In the Cape forest areas are settled many so-called 'poor whites,' a class of unfortunates all too numerous in South Africa, thanks mainly to the patriarchal system of the old Boers, which bred armies of *by-woners*—landless squatters and feckless hangers-on.

Fisheries.—Both the Cape and Natal have valuable fisheries and whaling industries. Whale oil, dried and preserved fish, and in recent years canned crayfish (£235,000 worth in 1925) are exported.

Railways and Harbours are, with few exceptions, government property, the responsible minister being advised by a board of commissioners. Their administration must be on 'business principles, due regard being had to agricultural and industrial development within the Union.' The South African Railways (State) have (1925) a mileage of 11,500, as against 7000 miles in 1910. (Cape, 4520 miles; Transvaal, 2808; Natal, 1378; O.F.S., 1420; South-West Africa, 1352.) The standard gauge is 3 feet 6 inches. The main lines run from the chief ports to the Rand goldfields. Cape Town is 956 miles (30 hours), Durban, 482 miles (21 hours) from Johannesburg; Lourenço Marques being 394 miles (16 hours). Electrification of certain sections is in progress. The Union railway system is linked up with South-West Africa, and with Rhodesia and the Belgian Congo (Cape to Cairo line). About half the exports and quarter the imports pass through Cape Town; about a third of both through Durban, which easily ranks first if tonnage of cargo shipped and landed be reckoned, not value. Table Bay (Cape Town), Mossel Bay, Algoa Bay (Port Elizabeth), Buffalo Harbour (East London), and Durban (Port Natal) have each a Harbour Advisory Board. Walvis Bay—part of the Union before the War—is now administered as part of South-West Africa. A new harbour is projected in N. Zululand, about 100 miles south of Delagoa Bay.

Trade and Commerce.—Customs Union was a forerunner of legislative union in South Africa. Competition for the overland trade of the goldfields was an endless source of strife between the Cape, Natal, Portuguese East Africa, and the inland states, railway rates, shipping freights, and customs tariffs proving pliable weapons in the contest. In 1889 the Cape and O.F.S. formed the first Customs Union in South Africa. Rhodes (c. 1894) urged a fiscal union plan, but Natal and the Transvaal fought shy. The South African Customs Union dates from 1903 and now includes—besides the four provinces—Southern Rhodesia, Northern Rhodesia, (Zambezi basin), South-West Africa, Basutoland, Swaziland, and the Bechuanaland

Protectorate. The Transvaal-Mozambique agreement (*inter alia*, to assure to Lourenço Marques 50 to 55 per cent. of the railway traffic to the Transvaal competitive areas) lapsed in 1923; but its clauses establishing virtual free trade between the Union and Mozambique were left in force. Free trade within the Union of South Africa is embodied in the constitution. The customs tariff is designed partly for revenue purposes, partly by way of protection; special dumping duties are imposed; preferential rebates of duty are granted in favour of the United Kingdom and the chief British dominions.

In 1925 two and a half million tons of cargo were landed and five million tons shipped at Union ports. The average annual imports (excluding specie) and exports (South African produce) rose in value from £38,000,000 and £56,000,000 respectively in 1910-14 to £67,000,000 and £81,000,000 in 1920-24. Two-thirds of the imports came from, and four-fifths of the exports went to, the United Kingdom and British Empire in 1925. Foreign trade is chiefly with U.S.A., Germany, France, Holland, and Belgium. Mining products account for nearly two-thirds of the total value of Union exports, of which the principal items in 1925 were: Gold (8,081,819 fine oz. = £34,329,376; 9,463,734 fine oz. = £40,199,380 in 1924); wool (£15,096,000); diamonds (2,591,239 carats = £8,605,525); maize and maize meal (2,124,500,000 lb. = £6,489,000); sheepskins (£1,566,000); wattle bark and extract (£1,109,000); coal (cargo, 1,758,000 tons = £1,071,000; bunkers, 1,963,000 tons = £2,243,000); hides (£912,000); angora hair (£836,000); sugar (£767,000); fruit, whale-oil, copper, cotton, goatskins, tin, ostrich-feathers (sadly fallen from nearly £3,000,000 in 1913), silver, fish, crayfish.

A Cape hundredweight = 100 lb.; Cape ton = 2000 lb. Other common South African weights and measures are: muid or sack = 4 schepels = 3 bushels; anker = 8 gallons (approx.); half aum = 16 gallons (approx.); leagner = 127 gallons (approx.); 1000 Cape feet = 1033 English feet; morgen = 2½ acres.

Finance.—The Union Ordinary Revenue rose from £17,228,000 in 1911-12 to £25,335,000 in 1924-5; expenditure from £16,547,000 to £24,527,000 (including £4,500,000 for provincial subsidies, but excluding nearly £5,000,000 railway debt interest). Public debt, £114,237,000 in 1911, was £214,332,000 by 1925 (over one-third internal). The Great War had added £32,000,000. The main sources of revenue are customs and excise, income-tax (on incomes over £300), supertax (over £2500), and dividend tax, interest, posts and telegraphs, mines (income-tax, share of profits, diamond export duty, licences, &c.), native taxes (poll and hut), stamp duties, &c. Railway revenue (over £20,000,000) usually exceeds working expenses by several millions.

The Pretoria branch of the Royal Mint (opened in 1923) makes British sovereigns and half-sovereigns, and South African silver and bronze coins. The non-commercial South African Reserve Bank (started 1921) is now the only bank allowed to issue notes.

Archæology.—Darwin held that Africa was the home of man's evolution, and the discovery in 1924, at Taungs in Bechuanaland, of the skull of a man-ape (*Australopithecus africanus*) was hailed as evidence of a pre-human stock in South Africa much more primitive than Pithecanthropus, the ape-man of Java. From other skulls found at Broken Hill, Rhodesia (1921), and at Boskop, Transvaal (1913), it has been concluded that the Boskop race (to whom palæolithic implements have been ascribed) followed Rhodesian man and themselves went down before the smaller, less-advanced Bushmen, whose cave paintings are

among the archaeological treasures of South Africa. Kitchen-middens along the coast bear witness to early occupation by 'Strandloopers'—Bushmen or Hottentots. Other antiquities of rare interest are the Zimbabwe ruins in Mashonaland and ancient gold workings in the Transvaal, which tell of northern Semitic invaders, perhaps in pre-Koranic times, a thousand years before the first Europeans (the Portuguese) set foot in South Africa. The story of European settlement in the sub-continent is sketched in the articles dealing with Cape of Good Hope, Natal, Transvaal, Orange Free State, and Rhodesia. Below is given in résumé the history of the Union of South Africa.

History—The road to Union was both long and rough; more than one false start was made; but obstacles that seemed insuperable were overcome at last. From the landing of Van Riebeeck (1652) to the accession of Queen Victoria (1837) there was but one government in South Africa, that of the Cape of Good Hope. The Great Trek led to the foundation of Natal and, ultimately, the Boer republics beyond the Orange River and Vaal. But no sooner were Orange Free State, Transvaal and Natal established as separate states than a reunion movement began. In 1858 Sir George Grey, the Cape governor, advocated confederation of the South African states as forming one nation. The O.F.S. Volksraad favoured federal union with the Cape Colony, but the imperial authorities turned a deaf ear. When next the question of union was raised the tables were turned. Lord Carnarvon, Secretary for the Colonies, proposed to follow up his success in Canada by South African Confederation, and in 1877 the Imperial Parliament passed an Act for the union under one government of 'such of the South African Colonies and States as may agree thereto.' Jealous of Downing Street interference, none of the governments concerned would have anything to do with the scheme as propounded by Sir Bartle Frere and J. A. Froude. Meantime the British annexation of the diamond fields had embittered the Free State. Then the goldfields and two Boer wars (1880-81 and 1899-1902) brought Anglo-Dutch animosities to a head, stained South Africa with blood—and made union under one flag not only possible but urgent. Post-war economic depression and inter-colonial wrangling stressed the extravagance and danger of four separate governments. Accordingly in 1906 the Cape Parliament asked Lord Selborne, the High Commissioner, to review the subject of Union. His historic memorandum appeared in 1907, and next year an Intercolonial Conference prepared the way for a National Convention, to which delegates (nominated by the governments) were appointed by the parliaments of the four colonies. Rhodesia was also represented. The Convention met in October, under the presidency of Sir Henry (afterwards Lord) de Villiers, Chief Justice, and by February 1909 prepared a Constitution in the form of a draft South Africa Act. In June, by referendum, Natal approved the draft Act, already accepted by the legislatures of the other colonies, and the South Africa Act (1909) was speedily passed by the Imperial Parliament. On May 31 (Union Day), 1910, the new dominion came into being.

In the first years of Union history was made apace. Before the South African nation was half-way through its teens, it had triumphantly surmounted a world war, a republican rebellion, a communist revolution, besides native outbreaks and Asiatic troubles. Viscount Gladstone, the first governor-general, called upon General Botha to form a ministry, and Botha's South African party (predominantly Dutch) defeated the

Unionists (under Dr Jameson) at the elections. In November 1910 the Union Parliament was formally opened by the Duke of Connaught. The public services were reorganised, and national substituted for divergent colonial administration in various state departments. A Defence Act was passed in 1912. In December of that year Botha eliminated from his ministry General Heitzog, minister for justice, leader of the ultra-Dutch wing of the S.A. party, whose followers seceded to form the National party, their strongholds being the Orange Free State and backveld areas. A 'General Strike' on the Rand was quelled by burgher forces in January 1914, and the leaders were deported. When the Great War broke out in August, South Africa released all imperial troops for service in Europe; carried out, under Botha in person, the conquest (1914-15) of German South-West Africa; suppressed a rebellion (October-December 1914) in the inland provinces, raised by De Wet, Beyers, ex-commandant-general of the Defence Force, and Maritz, commander of the Union troops on the German border; sent an expeditionary force (1916-18) under General Smuts, and—after his appointment to the Imperial War Cabinet—General Van Deventer, to German East Africa (now Tanganyika); and despatched overseas a volunteer brigade (which greatly distinguished itself in France at Delville Wood—'Devil's Wood'—July 1916), and a native labour contingent. The South African forces on war service numbered 146,515 Europeans, and 84,684 natives and coloured men (labour contingents); casualties totalled 18,642, including 6606 dead. These losses were aggravated by a terrible influenza epidemic which swept the Union (September-December 1918), killing 11,726 whites and 127,745 coloured people and natives.

The 1915 elections resulted as follows:—South African party, 54; Unionists, 40; Nationalists, 27; Labour, 3; Independents, 6. The government, however, could rely on Unionist support against the Nationalists, who openly preached republicanism. Soon after signing the Peace Treaty of Versailles that great patriot, Botha, died (August 1919), his right-hand man, Smuts, succeeding him as prime minister. The 1920 election produced a deadlock, giving the S.A. party only 40 seats; Unionists, 25; Nationalists, 45; Labour, 21; and Independents, 3. Republican aspirations preventing reunion of the two Dutch parties, the South African party was now amalgamated with the Unionists, the cabinet being reconstituted accordingly. The government triumphed at another general election in 1921, with 79 S.A. party members in the lower house, as against 45 Nationalists, 9 Labour, and 1 Independent. By referendum (1922) Southern Rhodesia decided against entering the Union. Economic depression had now set in; the Kimberley mines had closed down; strikes held up other mining industries; outbreaks at Lovedale, Queenstown, &c., betokened native unrest. A general strike, declared in March 1922, developed into a revolutionary movement on the Rand, and was only crushed after a week's fighting (with heavy casualties) between strikers' commandos and government forces. The white miners, resenting the displacement of European by coloured labourers, demanded the enforcement of regulations debarring non-Europeans from certain occupations; but the supreme court declared such a colour bar illegal in 1923. A pact between the National party and the Labour party enabled them, by a substantial majority (Nationalists, 63; Labour, 18; S.A. party, 53; Independent, 1), to defeat the government when Smuts suddenly went to the country in June 1924. Smuts had held cabinet rank without a break since 1907. A

coalition ministry came into office under General Hertzog, during whose régime, while the country began to recover from the post-war slump, racial feelings were roused and Labour sympathies strained by a proposal to eliminate the Union Jack from the South African flag, and by the prime minister's interpretation of dominion status within the commonwealth of British nations. At the same time the government's segregation policy inflamed Asiatic feeling in Natal and India; and a measure to legalise and extend the Colour Bar (rejected by the senate, where the S.A. party retained a majority, but forced through parliament at a joint session of the two houses in 1926) roused grave anxieties as the first instalment of a new native policy.

Southampton, a municipal, parliamentary, and county borough and important seaport, in the south of Hampshire, 12½ miles SSW. of Winchester, 23½ NW. of Portsmouth, and 79 SW. of London by the Southern Railway. It occupies a peninsula at the head of Southampton Water, and between the estuary of the Test on the west and south and the mouth of the Itchen on the east. There are considerable remains of the 14th-century town-walls, and four out of seven gates, the Norman Bargate being much the finest, though shorn of its effigies of Sir Bevis of Hampton and the giant Ascapard. Among many old buildings are the Tudor House (a museum), the adjacent Norman House, and the Woolhouse. Southampton is furnished with the usual municipal and other institutions, and has besides the Watts Memorial Hall (1876), a grammar school (1553; rebuilt and reorganised 1872-75), the Hartley Institution (1862; now Hartley University College, in new buildings since 1914), and the headquarters of the Ordnance Survey (1857). St Mary's Church (1878-79), by Street, is a memorial to Bishop Wilberforce. St Michael's Church, the oldest in the borough, contains Norman tower arches, and several of the private houses are of Norman architecture. The *Domus Dei*, or God's House, dates from the end of the 12th century, and is one of the earliest hospitals in England; in its chapel (now used for French service) are buried the Earl of Cambridge, Lord Scrope, and Sir Thomas Grey, executed by Henry V. for treason in 1415. The Pilgrim Fathers' monument (1913) is a beacon on a column 50 feet high, near the point where they embarked. Southampton docks, which are owned by the Southern Railway, are situated at the confluence of the rivers Itchen and Test, and the quays face on both estuaries. Started in 1836 by the Southampton Dock Company and transferred to the L. & S.W. Railway in 1892, they now include some fifty berths, six graving docks, and a monster

floating dock (1924) capable of lifting a ship of 60,000 tons displacement. A new dock is projected on the Test estuary between Royal Pier and Millbrook point. The docks are approached from the Solent by a wide and deep channel known as Southampton Water, from which vessels go direct to the berths without having to pass through locks. The largest merchant vessels in the world are domiciled here; and though comparatively small in area, the port has been so developed that it ranks as one of the largest in the United Kingdom as regards ships' tonnage. There are direct sailings for British and Continental ports, New York, Brazil, South and East Africa. Yacht and ship building, engine-making, and marine aircraft construction are actively carried on. Incorporated as a borough by Henry I., Southampton returns two members to parliament, and since 1898 has a bishop suffragan under Winchester. Pop. (1851) 45,305; (1901, with Shirley and Freemantle) 104,911; (1911) 119,012; (1921) 162,200.

Southampton supplanted the Roman station of *Claesentum*, which stood about one mile to the north-east, and its foundation is ascribed to the Anglo-Saxons. It is called Hamtune and Suth-Hamtun in the Saxon Chronicle, and Hamtune in the Domesday Book. After the Conquest Southampton, from which there was ready transit to Normandy, began to prosper rapidly, and in early times it traded with Venice and Bayonne, Bordeaux and Rochelle, Córdoba and Tunis. A great part of it was burned by the combined French, Spanish, and Genoese fleets in 1338, and in the following year its defences were strengthened. Southampton is the birthplace of Isaac Watts (to whom in 1861 a monument was erected in the West Park), of Charles Dibdin, and of Sir J. E. Millais.

SOUTHAMPTON WATER is a fine inlet, stretching north-westward from the point at which the Solent and Spithead unite. It is 11 miles long and nearly 2 miles wide. The Isle of Wight, which intervenes between the Southampton Water and the Channel, forms a magnificent natural breakwater, and occasions a second high-water two hours after the first. Southampton Water receives the Test or Anton, Itchen, and Hamble.

See the map at the article PORTSMOUTH; J. Silvester Davies's *History of Southampton* (1883); and *The Victoria County History of Hampshire*, vol. iii. (1908).

Southampton, HENRY WRIOTHESLEY, EARL OF (1573-1624), the friend and patron of Shakespeare (q.v.), was mixed up with Essex's insurrection, took part in the colonisation of Virginia, was imprisoned in 1621 for opposition to the court in parliament, and died of fever at Bergen-op-Zoom whilst fighting for the Dutch. See *Life* by Mrs Stopes (1922).

South Australia is that part of Australia which lies south of lat. 26° S. and between the longitudes 129° and 141° E., comprising an area of 380,070 sq. miles. On the west it is bordered by Western Australia, on the north by the Northern Territory and Queensland, and on the east by Queensland, New South Wales, and Victoria. The actual boundary between it and Victoria lies slightly west of long. 141°, owing to an error in the original survey.

The State is made up of two tablelands separated by a great valley, and two great plains bordering the eastern tableland on the east and north. The Great Valley is mainly occupied by Spencer Gulf and Lake Torrens; on its west, dotted with large dry lakes, rises a fairly level tableland averaging 1000 feet in height; eastwards the second tableland lies about half as high again, but slopes from nearly 3000 feet on the edge overhanging the valley to 500

feet where it is merged in the plains of the Murray basin. North of it, surrounding Lake Eyre, the second series of plains runs across the Queensland border. Embedded in the eastern tableland is a second valley, chiefly occupied by St Vincent's Gulf, but including also the lowlands between Adelaide and Gawler. Till lately the settled area was confined to these lowlands, the tableland above them, and a patch round Mount Gambier in the far south-east; but recent improvements in wheat-growing have made cultivable great areas of the Murray basin, between the river and the Victorian border, and the success of an irrigation colony at Renmark has opened the way for further settlement along the north bank of the Murray, which will be supplied with water from an immense reservoir at Lake Victoria in New South Wales.

Apart from those already mentioned, the chief geographical features of the State are the lower Murray and the series of lagoons (Alexandrina, Albert, the Coorong) at its mouth; the inland lakes and swamps, of which Lake Torrens is a cut-off from Spencer Gulf, Lake Eyre a quickly evaporating reservoir for the rivers of western Queensland, and Lake Gairdner a still more evanescent rain-water tank; the ridges of the eastern tableland, of which the most noticeable are Flinders Range, running north from Spencer Gulf (St Mary's Peak, 4000 feet; Mount Remarkable, 3178 feet), and Mount Lofty Range, east of Adelaide (Mount Lofty, 2334 feet); and Kangaroo Island (q.v.). The highest point in the State is Mount Woodruffe (about 5000 feet) in the Musgrave Ranges far to the north-west.

History.—The Dutch ship *Gulden Zeepaert* in 1627 sailed along the south coast of Australia, eastward of Cape Leeuwin, as far as the western borders of South Australia. The first Englishman to see its shores was Captain Grant, who in 1800 sighted the coast near Mount Gambier; and two years later Flinders explored the two great gulfs and Kangaroo Island, and on his way east met the French navigator Baudin in Encounter Bay. These distant views did not encourage colonisation; but Sturt, voyaging down the Murray in 1830, discovered good pastoral land along the lower course of that river, and the next year a private company formed in England put forward a scheme of settlement. In 1834 a body of 'Colonisation Commissioners for South Australia' was created by act of parliament to deal with the new colony's immigration and land settlement in accordance with the views not long before urged publicly by Edward Gibbon Wakefield (q.v.); in other respects it was decided that the colony should follow the usual type of crown colony. The first settlers landed on Kangaroo Island in July 1836 but removed almost at once to the mainland plain on which Adelaide now stands, and on 28th December the colony was formally constituted at Glenelg. For a few years progress was slow, but the discovery of copper in 1842 and 1845, aided by the excellent administration of Sir George Grey (q.v.), greatly stimulated South Australia's prosperity; and, though at first the gold discoveries in the eastern colonies drew population away, it was soon found that South Australia was well fitted to provide the wheat for which the hordes of Victorian diggers were clamouring. Wheat and wine have since been its staple products. In 1901 it became a State of the Australian Commonwealth.

Geology.—Geologically South Australia has two well-marked divisions—the southern (tablelands, great valley, and eastern plain) and the northern or Lake Eyre basin. The foundation of Archæan rocks on which both divisions rest comes to the surface on Kangaroo Island (where it runs east and west), in patches on Eyre and Yorke Peninsulas,

on the eastern edge of the Mount Lofty Range, and between Lake Frome and Hergott Springs. Plutonic rocks of similar age occur near the New South Wales border and in the Gawler Ranges on the western tableland. Above these come the Cambrian deposits which are the special geological feature of the State; they form the backbone of the eastern tableland from lat. 30° southwards to Encounter Bay, and in their southern position show indisputable evidence of glacial action. West of the Great Valley sandstones (possibly Devonian) cap the Archæan strata; and the Nullarbor Plains, in the extreme west of the State, are Eocene limestone, which also shows up along the Murray. The rest of the southern division is overlaid with recent alluvial deposits. In the northern area the Archæan foundation is in evidence in the Peak and Denison Ranges west of Lake Eyre, and reappears in the Macdonnell Ranges across the border of the Northern Territory. Upon it lies a thick Jurassic deposit containing workable brown coal, and upon that a series of Cretaceous clays, apparently an extension of the Queensland formation known as the 'Rolling Downs' beds, and serving the same purpose of capping impermeably the artesian waters of central Australia. Above the clays occur at intervals patches of desert sandstone (probably Upper Cretaceous), and on the lower Barcoo there are Pleistocene deposits containing fossil remains of large marsupials, fresh-water crocodiles, and lizards, all now extinct. In the south-eastern corner of the State is an area dotted with extinct craters, the basalts from which overlie beds of Tertiary limestone; Mount Gambier is the best known. Similar basalts occur on Kangaroo Island.

Climate, Fauna, Flora.—See AUSTRALIA.

Industries.—The pastoral industry occupies the greater part of the interior, whose aridity unfits it for anything else, and makes it not very suitable even for that; the State contains only 8 per cent. of the sheep, 11 per cent. of the horses, and less than 3 per cent. of the cattle of the Commonwealth. But it is stated on good authority that South Australian sheep bear a greater weight of wool than those of the other States, the average over a long series of years being 8 per cent. higher than that of Victoria. In forestry and mining also the State's natural resources are limited; the usual Australian metals and minerals are found, but only copper has been seriously profitable. The principal mines are at Wallaroo and Moonta, in the Yorke Peninsula; four to five thousand men are engaged in the industry. Recently great iron deposits (the estimate of ore in sight is 21,000,000 tons) at Iron Knob, south-west of Port Augusta, have been acquired and are being exploited by the Broken Hill Proprietary Company. Radio-active pitchblende has been obtained at Olary, on the line to Broken Hill.

The State's chief industry, as has been already said, is agriculture, which in this case means practically wheat-growing. From 1880 to 1908 the cultivated area remained steady at 2 to 2½ million acres; developments in the Murray basin, already referred to, then began to increase that area, which is now over 3½ million acres and still growing (about 70 per cent. in wheat, and 16 more in wheaten hay—i.e. wheat sown specially to be cut unripe for making hay). Per head of population the cropped area is more than double that of any other State except Western Australia. Nearly 44,000 acres are under vines; Victoria, which comes next in this respect, has only 32,000. The annual wine-production in 1918-23 averaged 7 million gallons (nearly 73 per cent. of the Commonwealth's total) against Victoria's 1,656,000. In 1925 it was 10½ million gallons, 79 per cent. of the Australian yield. In table-grapes, on the other hand, South

Australia produces barely 11 per cent. of the Commonwealth's total. The consistently admirable system of land laws has greatly aided the settlement of 'small farmers' on limited agricultural areas.

Population.—At the census of 4th April 1921 the population of South Australia was 495,160, almost equally divided between the sexes. There were also 1609 aborigines living in a civilised or semi-civilised condition, and possibly 3000 more within the State boundaries in scattered and uncivilised communities. On 31st March 1926 the population was estimated at 555,740. Eighty per cent. of the whites are Australian born, and nearly 16 per cent. were born in the United Kingdom; a small but compact colony of German origin is centred in the hill-country east of Adelaide. The growth of the population was steady up to 1885, when the area then capable of profitable agriculture was fully occupied; it then slackened considerably, and was for many years less than 1 per cent., but is now recovering. Fifty-five per cent. of the inhabitants live in or near Adelaide. In regard to religion, the chief feature is the great percentage of Methodists (24, as against 12 for the Commonwealth as a whole), largely due to the former influx of Cornish miners to the copper-mines. The educational system is that usual throughout Australia (see EDUCATION); there is no state supervision of private schools, although a law of 1878 provides for it if asked for. The University of Adelaide, established in 1874, has 18 professors and 119 lecturers for about 1450 students, of whom 818 are undergraduates, besides a Conservatorium of Music with a staff of 10 teachers and nearly 400 students. More than a third of its income is derived from public funds. There are also several Schools of Mines, of which the principal one at Adelaide has nearly two thousand students.

Government, &c.—The State government is of the usual 'responsible' type, with a Governor appointed by the Crown, a Council of twenty members, and an Assembly of forty-six. Six ministers administer nine departments. The councillors are elected for six years on a property qualification, the Lower House for three years by adult suffrage; the members of both Houses are paid £200 a year. The State sends six senators and seven representatives to the Federal parliament.

Imports from overseas are valued at about 14 millions, and exports at a little over 19 millions. The principal exports are flour (especially to Java and South Africa), wheat, and wool (mainly to Britain). The State owns 2452 miles of railway, of which 1190 are on a gauge of 5 feet 3 in., and the rest on one of 3 feet 6 in.; those on the broader gauge connect with the Victorian lines. Parts of the State are also served by two Federal railways, one connecting Port Augusta at the head of Spencer Gulf with Coolgardie in Western Australia, the other (which used to belong to the State but was taken over by the Commonwealth) running from Port Augusta northwards to Oodnadatta, and intended eventually to connect with a line now under construction southwards from Port Darwin in the Northern Territory. The Coolgardie line is of 4 feet 8½ in. gauge, as all Federal lines are intended to be, but the conversion of the Oodnadatta line has not yet been undertaken. It has been proposed to continue the Federal main line eastwards across South Australia to join up with the new 4 feet 8½ in. line that traverses New South Wales from Sydney to Broken Hill, thus giving an uninterrupted passage on the one gauge from Coolgardie to any part of New South Wales and avoid the long detour southwards by Adelaide and Melbourne. The State's only private line runs from Iron Knob on Eyre Peninsula to a port on Spencer Gulf,

whence the iron ore is conveyed to smelters at Newcastle in New South Wales.

See AUSTRALIA and works there cited. Woods's *History of the Province of South Australia* (1894) and Gordon's *Handbook of South Australia* (1908) were published under official auspices. Gregory's *The Dead Heart of Australia* (1906) gives a graphic and generally trustworthy description of the central area, and Cockburn's *Nomenclature of South Australia* (1908) is useful in detail. Henderson's *Life of Sir George Grey* deals fairly with the history of the Province's early years. The South Australian Public Library is now publishing a series of historical monographs, among which Threadgill's *South Australian Land Exploration, 1856 to 1880*, is worth special study.

South Bend, capital of St Joseph county, Indiana, on the St Joseph River (navigable for small steamers), 86 miles by rail E. by S. of Chicago. It has large manufacturing factories of automobiles, wagons, agricultural implements, furniture, woollens, paper, sewing-machine fixtures, &c. In the suburb of Notre Dame, 2 miles to the north, is a Catholic university. Pop. (1880) 13,280; (1890) 21,819; (1920) 70,983.

South Bethlehem. See BETHLEHEM (Pennsylvania).

Southbridge, a town of Massachusetts, on the Quinebaug River, 70 miles by rail SW. of Boston, with manufacturing factories of cottons, woollens, optical goods, cutlery; pop. 14,000.

South Carolina, one of the original states of the American Union, with an area of 30,570 sq. m., including 400 sq. m. of water-surface, is nearly triangular in outline, and is bounded on the N. and NE. by North Carolina, SE. by the Atlantic Ocean, and SW. by Georgia. Numerous islands near the southern part of the coast are separated from the mainland and from each other by shallow sounds and inlets. For 100 miles inland the land is generally low and level, much of it still covered with pine forests (*Pinus palustris*). West of this alluvial plain is a range of undulating sandhills about 60 miles in width. This 'middle country' was long the least fertile part of the state. Farther west the 'ridge-country' rises, generally abruptly, from the Savannah to the Broad River on the north, presenting a region of rare beauty and fertility. The average elevation of the western third of the state is nearly 2000 feet above the sea-level. Mount Pinnacle, Caesar's Head, and Table Mountain, belonging to the Blue Ridge range, in the north-west part of the state, rise to the height of about 4000 feet. Geologically the eastern part of the state is Quaternary or alluvial and the western is Archæan, with extensive Tertiary and older formations intermediate. Most of the rivers—the largest the Santee (q.v.)—are navigable by steamboats nearly to the foot-slope of the ridge region, where they supply abundant water-power.

The state has varied mineral products. The gold-belt extends from the North Carolina line in a south-westerly direction, but the output is insignificant. Granite is abundant in Abbeville, Fairfield, and Newberry counties; and itacolumite, a flexible sandstone, is quarried for grindstones in Spartanburg. Kaolin of superior quality, and used for artificial teeth, is obtained in Chester county. Pliocene marl is abundant in Horry, Sumpter, and Marlborough counties. Post-pliocene is found in Edisto Island, and near the Savannah, Santee, Ashley, and Cooper rivers. But the most important mineral product of South Carolina is its phosphate rock, the deposit extending about 70 miles from the mouth of the Broad River near Port Royal to the head-waters of the Wando, north of Charleston. Its direction is parallel with the coast, and its width in some places is 30 miles. It crops out

near the Ashley River, where it was first observed. This great phosphate bed is generally covered with Quaternary clays and sands, and its nodular phosphatic layer rests upon deep strata of calcareous marl, beneath which Cretaceous marls extend along the entire eastern part of the state. The product in 1893 amounted to 502,564 tons, but in 1920 it had decreased to 44,141 tons, in consequence of the exhaustion of supplies and of the discovery in Florida of larger beds of similar phosphate. It is obtained as a tribasic phosphate, and is used mainly in the manufacture of manure (superphosphates). The average of lime phosphate is from 52 to 60 per cent. of the rock. Gray iron ore (magnetite) is found in Union, York, and Spartanburg counties; and copper pyrites (chalcopyrite), galena, limonite, malachite, pyrolusite, and pyromorphite or phosphate of lead have been found in the western part of the state, and sand for glass in Aiken and Barnwell counties. Deer, wild turkeys, raccoons, foxes, squirrels, and other small game are still numerous in the forests; and the rivers, sounds, and inlets are stocked with a great variety of fish. Shad and oyster fisheries are valuable. Alligators of large size inhabit the tidal rivers.

South Carolina, called the Palmetto State from the growth of the cabbage-tree (*Sabal Palmetto*) near the coast, ranks twenty-sixth in point of population, and is one of the two states—Mississippi is the other—where the negro population outnumbered the white. By the census of 1890 the population was 1,151,149—692,503 negro, 458,454 white, 172 Indian, and 20 Asiatic; in 1920 it was 1,683,724—864,719 negro, 818,538 white, 304 Indian, 163 Asiatic. There are forty-six counties. Charleston is the largest city (pop. 1920, 67,957), and Columbia (37,524) is the capital. The mild climate is salubrious except in the rice-lands, which are rendered unhealthy by the presence of malaria. The low islands along the coast afford desirable summer-resorts, as well as the western mountain-region known as 'the land of the sky.' The average rainfall in the eastern part is from 42 to 44 inches. The coast lies within the usual limits of West India cyclones, which are often destructive of life and property. Charleston (q.v.) suffered severely from a cyclone in 1885, and much more terribly, from an earthquake in 1886.

Economically South Carolina is mainly an agricultural state. Cotton is the chief staple. Tobacco is also grown; and maize, oats, wheat, and rice are the principal cereals. Peaches and apples among fruits, and asparagus and beans among vegetables, are the most valuable. There is some stock-raising and wool-growing. Of industries outside agriculture the making of cotton goods is the chief; lumbering (yellow pine, cypress, red gum, &c.) is also carried on; and there are manufactures of cottonseed oil and cake, fertilisers, flour, tar, rosin, turpentine. Charleston, Georgetown, and Beaufort are the chief centres of commerce, rice, cotton, lumber, phosphate, naval stores, cottonseed, cottonseed oil, oil cake, fish, and spring vegetables being the principal exports.

In 1562 John Ribault, at the head of a party of French Protestants sent over by Admiral Coligny, built a fort on an island in the harbour of Port Royal, and named it *Arx Carolina*, in honour of the king Charles IX. The twenty-six colonists left by Ribault soon abandoned the fort to return to France. In 1630 Sir Robert Heath obtained a grant from Charles I. reaching from latitude 36° N. to the Gulf of Mexico, but failure to colonise forfeited the title. In this grant the territory was named *Carolina* for Charles I. In 1662 Charles II. granted to Lord Clarendon and seven associates all the territory from the Atlantic to the Pacific

lying between parallels 31° and 36° N. Two years later the northern boundary was made 36° 30'. In 1670 three ship-loads of English settlers under William Sayle landed at or near Port Royal, but the next year moved to the right bank of Ashley River. In 1680 they moved again to the present site of Charleston. The proprietary government under the 'fundamental constitution,' drawn up by John Locke (see NORTH CAROLINA), lasted till 1729, when George II. bought out the proprietors and divided Carolina into two royal provinces. Subsequently South Carolina became one of the most flourishing of the British colonies and attracted an intelligent and enterprising class of settlers from Europe, including many French Huguenots, who came soon after the revocation of the Edict of Nantes in 1685. Hence the Gallic origin of so many distinguished names in the history of the state.

Sir John Yeamans, who had been appointed governor, brought from Barbados two hundred negro slaves in 1671. The blacks in a few years nearly equalled the whites, and since 1820 have been more numerous in the state. During the revolutionary war South Carolina furnished her full quota of men and means, and suffered much from British invasion and occupation. This state was the first to ratify the Articles of Confederation, 5th February 1778, and the eighth to ratify the constitution, 23d May 1788. In 1832 a convention called by the legislature passed the ordinance of Nullification (q.v.). South Carolina was the first state to secede from the Union. A convention called by the legislature met on the 17th December 1860, and passed an ordinance of secession by a unanimous vote on the 20th. Six sister slave-states soon followed the example of South Carolina, and formed the Southern Confederacy, which was subsequently increased by four more. South Carolina was readmitted into the Union on 25th June 1868. Since the accomplishment of reconstruction the state has attained a high degree of prosperity. It sends seven representatives to the national congress. School attendance since 1922 has been compulsory. There are separate schools for white and coloured children. For higher education there are the University of South Carolina at Columbia, Clemson Agricultural College, Charleston City College, various denominational colleges (one for coloured students), and colleges for women, a college for coloured youths, a military academy, and a normal and industrial college.

See UNITED STATES; Histories of South Carolina by Ramsay (1867), McCrady (various works, 1897-1901; continued by Roy Smith, 1904), Snowden (editor, 5 vols. 1920).

South Chester. See CHESTER.

Southcott, JOANNA, founder of the Christian sect known as Southcottians, was born in April 1750 at the farm of Tarford in the parish of Ottery St Mary, Devon. As a girl she did dairy-work at home, and later, till over forty, found employment in various families in Devon as domestic servant and as assistant in the upholstery business. Her service was faithful and her character on all showing blameless; but in the view of her father she was unduly religious. In 1792, claiming to be divinely visited, and judging herself to be chosen to warn the world of the imminence of the second coming, an event eagerly sought for by her as by all Southcottians, she began prophesying in prose and in verse; and many of her prophecies, as to war, harvests, &c., were shortly fulfilled. Publications onwards from 1801 brought growing note, and as the result of a trial of her prophetic gifts, held in December 1801 at Exeter, she made constant

adherents, among others, of the engraver William Sharp, who in 1812 engraved her likeness, and of several clergymen of the Church of England. In 1802, at Sharp's suggestion, she came to London, where further trials brought widened fame, and organisation was given to the movement, preachers appearing and services being held; while between 1802 and 1808, when the practice was discontinued, over 14,000 seals (written pieces of paper signed by Joanna herself and by the recipient and sealed on the back when folded up) were issued (not seemingly sold) to adherents. In 1813 she announced that she was in the sixty-fifth year of her age (1814) to bear by the power of the most high a second Shiloh or Prince of Peace. Signs of pregnancy, even on medical testimony, duly appeared, and great excitement prevailed; while, with the view of providing a father at law, an earthly marriage is said to have been entered into. But on 27th December 1814 Joanna merely died. An autopsy revealed no pregnancy. No organic cause of death appeared, but the brain owing to the high state of putrefaction was not examined, and apoplexy was given as the cause of death. The appearances of pregnancy were set down (not necessarily fairly) to deception; followers, however, continued in their belief, some at the time as afterwards alleging that Joanna would yet return to give birth to a literal child, others maintaining that Revelation xii. had been fulfilled, a child being born, but a spiritual child, and one 'caught up to God, and to his throne.' In her lifetime Joanna's followers are said to have numbered 100,000, but later dwindled to a handful, a revival occurring, however, in the early 20th century. From the time of the founder a 'Lifting up of Hands' has been held on 12th January (New Year's Eve, old style), when petition is made for the overthrow of evil and the establishment of Christ's kingdom on earth. Outside Britain there are believers in the United States, Canada, Australia, New Zealand. And from the original sect have sprung sects led by John Ward, John Wroe (Christian Israelites), James White (New and Latter House of Israel). Joanna's writings (latterly dictated) are numerous. Among the chief are *The Strange Effects of Faith* (1801-2), books of sealed prophecies and visions (1803-5), *A Dispute between the Woman and the Power of Darkness* (1802), *A Warning to the World* (1804), *The Trial of Joanna Southcott, 1804* (1805), *The True Explanation of the Bible* (1804-10), *The Book of Wonder* (1813-14, relating to the birth of Shiloh), *Prophecies announcing the Birth of the Prince of Peace* (1814). Joanna early adopted the plan of sealing up her writings and having them placed in a box, to be opened when the events predicted matured. The box, strongly nailed and corded, is, according to prophecy, to be opened only when in a time of crisis the bishops of the Church of England demand it, a preliminary study by the bishops of Joanna's work and a subsequent examination by them of such writings of hers as are revealed being, however, imposed as necessary conditions. Willingness has been expressed, as in 1918 and 1924, to open the box, but the conditions enjoined have been rejected, and the box remains unopened. In their lifetime secrecy is preserved as to the custodians of the box. The appearance of rival boxes is said to be due to the existence of boxes of relics belonging to old believers. Two were opened in 1925, one at Hammersmith holding nothing of real value, the other near Bournemouth containing interesting Southcottian manuscripts. According to some, Joanna Southcott foretold the Great War and the feminist movement. See Alice Seymour, *The Express* (2 vols. 1909), and C. Lane, *The Life and Bibliography of Joanna Southcott* (Exeter, 1912).

South Dakota, one of the northern central states of the American Union, ranks fourteenth in area and thirty-seventh in population. It is bounded on the north by North Dakota, on the east by Minnesota and Iowa, on the south by Nebraska, on the west by Montana and Wyoming, and has an area of 77,615 sq. m., including 747 sq. m. of water. The river Missouri running north and south (and eventually forming the south-east boundary) cuts the state into two nearly equal portions. The eastern half, mostly undulating prairie, contains two plateaus, the Coteau du Missouri and the Coteau des Prairies (where there are some small salt lakes), divided by the valley of the James or Dakota River. The western half is more broken country, watered by the Grand, Owl, Cheyenne (two forks), Bad and White Rivers, all of which flow into the Missouri. The Black Hills on the south-west form a rugged and forested region, nearly 5000 square miles in area, whose highest point, Harney Peak, reaches 8200 feet. East of the Black Hills are the Bad Lands (see MAUVAISES TERRES). The climate is dry and healthy, though extremes of temperature are recorded, and the rainfall is generally sufficient for cultivation purposes except in parts of the west.

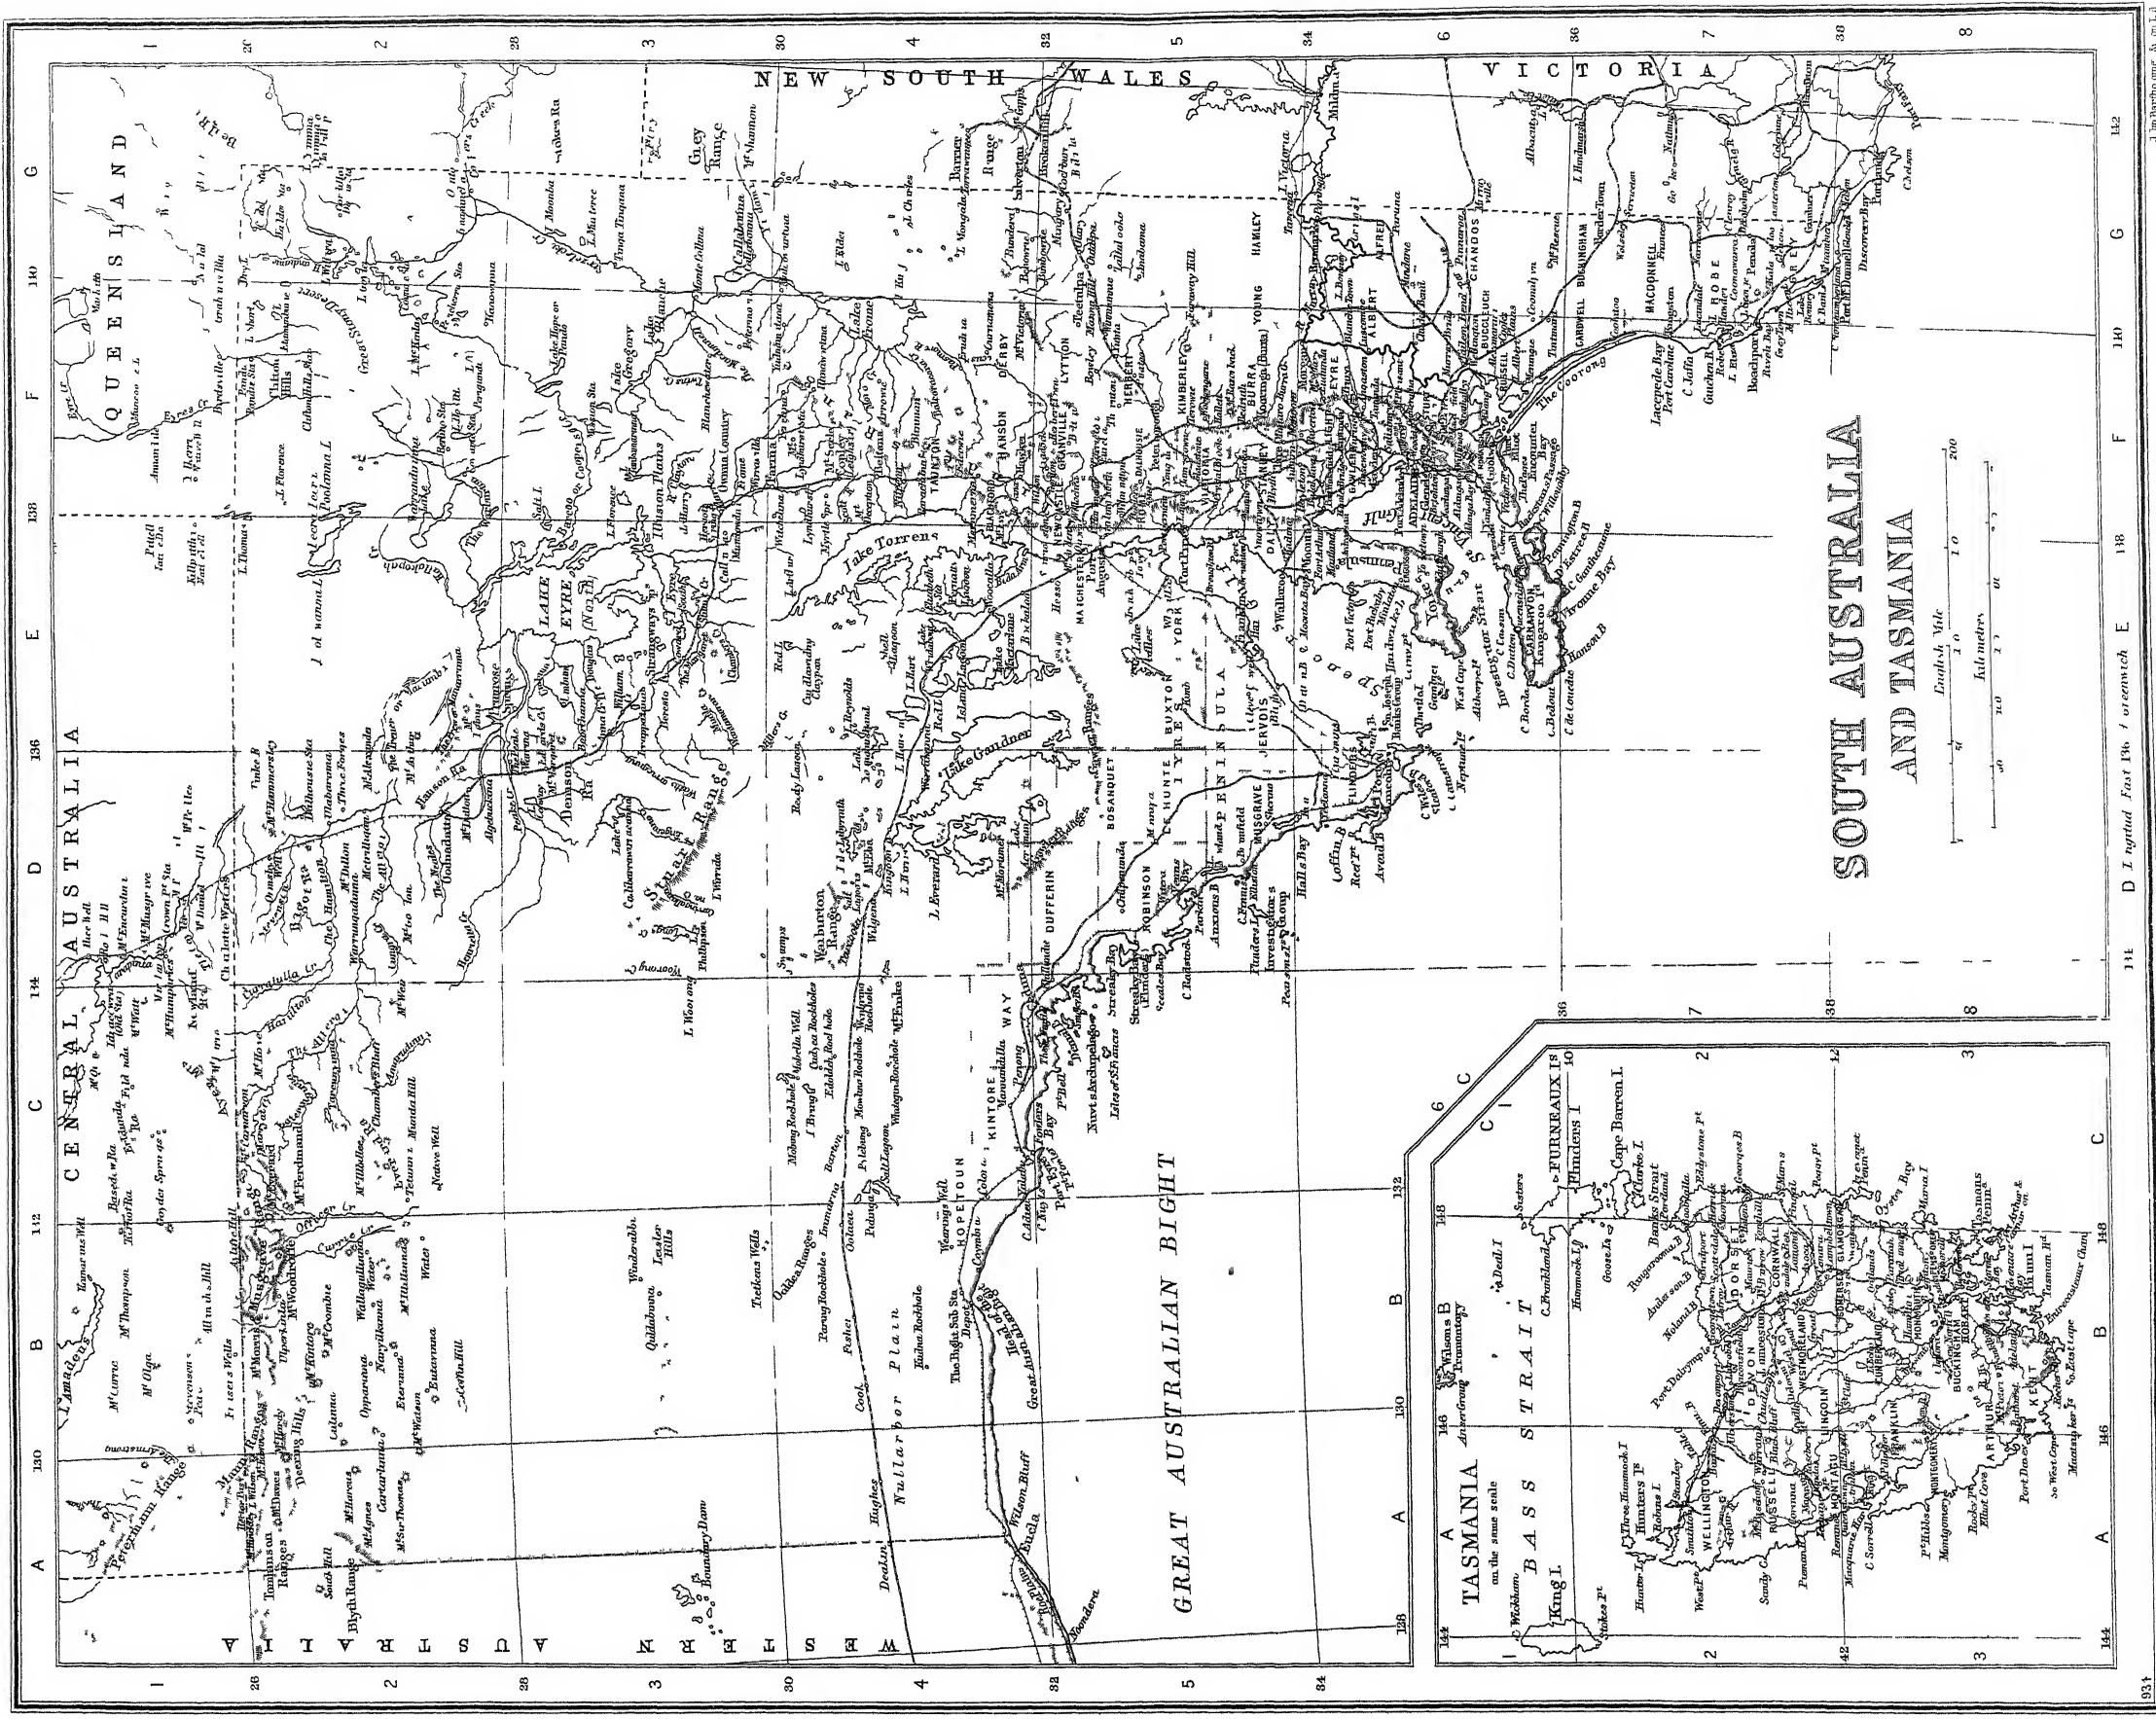

Slightly over two-thirds of the total area are given over to farming, the chief crops being corn, oats, wheat, and barley. Agriculture is pursued mostly in the eastern portion of the state, but in the north-west irrigation has brought many thousands of acres into cultivation. The number of live-stock is considerable, and among the Bad Lands cattle-raising is important, while there is a certain amount of timber available. In the north-west there are lignite coalfields and among the Black Hills there are rich gold-mines (see GOLD); other minerals found are silver, tin, copper, and lead. The principal industries are the making of butter and cheese, flour and gist milling, and manufacturing of lumber products. There are about 4300 miles of railway in the state.

There are numerous elementary and secondary schools, while the state educational institutions include a school of mines, an agricultural college and a university (founded 1882) at Vermilion. There are also various sectarian colleges and three Indian schools. South Dakota sends two senators and three representatives to the Federal Congress. It was separated from North Dakota (q.v.) in 1889, at which date the two new states were both admitted to the union. The state capital is Pierre (3000), but Sioux Falls (25,000) and Aberdeen (15,000) are the principal towns. Population of South Dakota (1890) 348,600; (1920) 636,547, of whom over 16,000 are Indians and about 60,000 are foreign-born whites.

South Easton, a former borough of Pennsylvania, at the mouth of the Lehigh River, opposite Easton, to which it has been annexed since 1890.

Southend-on-Sea, an Essex watering-place, at the mouth of the Thames estuary, 42 miles E. of London. Dating from a visit here of Queen Caroline and the Princess Charlotte in 1804, it was in great part built by Sir S. Mouton Peto (1809-89), has a public hall (1872), a new pier, over a mile in length, with tramway and concert-room, and a handsome eight-mile promenade. Southend-on-Sea is a municipal (1894), a county (1914), and parliamentary (1918) borough. Pop. (1851) 2462; (1881) 7979; (1901) 28,857; (1911) 62,713; (1921) 106,021.

Southern Cross, one of the star groups in the southern hemisphere of the heavens. It lies in right ascension 12 hours, and dec. 60° S., being thus a considerable distance from the south pole of the

heavens. It was added to the list of constellations by Royer in 1679. The four principal stars form a

Quadrant of the Southern Heavens from the Pole to the fortieth degree, showing the Southern Cross, *a*, and the Triangle, *b*. The two bright stars at *c* are α and β Centauri.

rough cross when seen above the pole. The figure is of considerable size, being about 6° of dec. in height.

Southerne, THOMAS, dramatist, known as 'honest Tom Southerne' in the world of his day, was born at Oxmantown in County Dublin in 1660, studied at Trinity College, Dublin, and entered at the Middle Temple, London, but in 1682 began his career as playwright with a compliment to the Duke of York in *The Loyal Brother, or the Persian Prince*. Dryden wrote the prologue and epilogue, raising his fee on the occasion, and Southerne had the honour of finishing Dryden's *Cleomenes, or the Spartan Hero* (1692). Southerne served a short time under the Duke of Berwick, and at his request wrote the *Spartan Dame*, receiving £120 for the copyright. His best plays, both tragedies, were produced in the reign of William III.—*The Fatal Marriage* (1694), and *Oroonoko* (1696), based on Aphra Behn's novel. His comedies are thin, and hardly more decent than the rest in that day. Southerne contrived to thrive in his vocation, and is pleasantly described as a venerable old gentleman, regular in attendance on evening prayers, always neat and decently dressed, commonly in black with his silver sword and silver locks. Pope describes his friend as him whom Heaven sent down to raise the price of prologues and of plays. He died 26th May 1746.

Southernwood (*Artemisia Abrotanum*), a shrubby species of Artemisia (see WORMWOOD), found wild in south Europe, and cultivated in old-fashioned gardens for its pleasant aromatic odour.

Southey, ROBERT, poet-laureate, was born at Bristol on 12th August 1774. His father, Robert Southey (1745–92), was an unlucky linen-draper; his mother, Margaret Hill (1752–1802), came of good old yeoman ancestry, and was a bright, sweet-tempered woman, who could whistle like a blackbird. Much of his lonely childhood was passed with his mother's half-sister, Miss Tyler (1739–1821), a rich, genteel old maid who hated noise and matrimony, and had a passion for cleanliness and the drama. With her he saw many plays; read Shakespeare and Beaumont and Fletcher, Hoole's *Tasso* and *Ariosto*, the *Faerie Queene*, Pope's *Homer* and Sidney's *Arcadia*; and himself scribbled thousands of verses. He had meanwhile had four schoolmasters, and in 1788 was placed by

an uncle, the Rev. Herbert Hill, at Westminster. There Picart's *Religious Ceremonies* led him 'to conceive a design of reendeering every mythology the basis of a narrative poem'; there he formed lifelong friendships with C. W. W. Wynn and Grosvenor Bedford; and thence in 1792 he was expelled for writing an article against flogging in a school magazine. Next year, however, he entered Balliol College with a view to taking orders. He went up to Oxford a republican, his head full of Rousseau and 'Werther,' his religious principles shaken by Gibbon; and he left it in 1794 a Unitarian, having learnt a little swimming and a little boating, and ingrained his very heart with Epictetus. And at Oxford he had a visit from Coleridge, who infected him with his dream of a 'Pantisocracy' on the banks of the Susquehanna. The Pantisocrats required wives; and wives were forthcoming in three Miss Frickers of Bristol. The eldest, Sara, fell to Coleridge; the second, Edith, to Southey; and Mary, the third, to a Robert Lovel, who with Southey in 1794 published a booklet of poems, and died two years afterwards penniless. The Pantisocrats furthermore required money, and money was not forthcoming; so, having tried medicine, and been sickened by the dissecting-room, having been turned out of doors by his indignant aunt, having lectured with some success, and having on 14th November 1795 secretly married his Edith, Southey started the same day alone on a six months' visit to Lisbon, where his uncle was chaplain to the British factory. There he laid the foundation of his profound knowledge of the literatures and history of the Peninsula. He returned to England to take up law, but reading Coke to him was 'threshing straw'; so after sundry migrations—Westbury near Bristol, Burton near Christchurch, Lisbon again for a twelvemonth (1800–1), and Ireland (a brief secretaryship to its Chancellor of the Exchequer), with intervals of London—in September 1803 he settled at Greta Hall, Keswick, in the Lake Country. The Coleridges were there already, and thither came Mrs Lovel: three households were to rest on Southey's shoulders.

His school friend Wynn allowed him £160 a year from 1796 till 1807, when a government pension of a like amount was granted him (he was turning meanwhile a Tory), and on this he devoted himself to a life of strenuous, incessant authorship. *Joan of Arc* had already appeared in 1795, and *Thalaba* in 1801; there followed *Madoc* (1805), *The Curse of Kehama* (1810), *Roderick* (1814), *History of Brazil* (1810–19), *Lives of Nelson* (1813), *Wesley* (1820), and Bunyan (1830), *A Vision of Judgment* (1821), *Book of the Church* (1824), *History of the Peninsular War* (1823–32), *Colloquies on Society* (1829), *Naval History* (1833–40), and *The Doctor* (1834–47), in which comes the nursery classic of 'The Three Bears.' His works number nearly fifty, and fill more than a hundred volumes; and to them must be added his contributions to the periodicals—to the *Quarterly* alone ninety-three articles (1808–38). These paid him handsomely, so that he died worth £12,000; but the *History of Brazil* brought him in eight years only the price of one article, and *Madoc* in a twelvemonth only £3, 17s. 1d.—*Madoc*, which Scott read and thrice re-read, and which Southey himself with naive vanity admitted to be 'the best English poem since *Paradise Lost*.' His life was a busy and happy one: at forty-six he could say, 'I have lived in the sunshine, and am still looking forward with hope.' It flowed quietly on, the chief events in it his visit to Scott and Scotland (1805), his first meeting with Landor (1808), the visits from Shelley and Ticknor (1811, 1819), his appointment to the laureateship (1813), the death of his first boy

Herbert (1806-16), the surreptitious publication of his revolutionary drama *Wat Tyler* (1817; written 1794), little tours in Belgium (1815), Switzerland (1817), Holland (1825, 1826), and France (1838), an honorary D.C.L. of Oxford (1820), his return *vs* M.P. for Downton (unsolicited and declined, 1826), and Peel's offer of a baronetcy, with the welcome addition of £300 a year to his pension (1835). It came at a time of sorrow, for his wife, who had 'for forty years been the life of his life,' had six months before been placed in an asylum, and though she was brought back to Keswick, she was brought back only to die (1837). Southey never held up after that, though in 1839 he married the poetess Caroline Anne Bowles (1787-1854), for twenty years his friend and correspondent, and returned with her to Greta Hall, intending resolutely to set about two great works which he had long had in contemplation—a History of Portugal and a History of the Monastic Orders. It was not to be, for Wordsworth in 1840 found him vacuous, listless in his noble library, the 14,000 books he had collected, 'patting them with both hands affectionately like a child.' The end came on 21st March 1843; he is buried in Crosthwaite churchyard.

Macaulay in 1830 expressed a doubt whether 'fifty years hence Mr Southey's poems will be read; the doubt has been amply justified. No poet probably so well known by name is so little known by his poetry. There are some short exceptions of course—the 'Holly Tree,' 'Battle of Blenheim,' 'Stanzas written in my Library,' half-a-dozen more. But the 'Simorg,' the 'Glendoveers,' 'Mohareb'—how many can localise these creations of Southey's muse? His epics repel, not so much by prolixity or by their irregular, sometimes rhymeless metres, as by the unreality of their fact and fancy. They remind us of scene-paintings; and a scene-painting even by Roberts will fetch just nothing in the auction-room. With Southey's prose it is otherwise. He wrote out of the fullness of knowledge, for something more than the mere sake of writing; and his was that rarest gift of good pure English. Yet even here he wrote far too much, and he was often unhappy in his choice of subjects. One book alone by him, the *Life of Nelson*, belongs to universal literature. But though there have been better poets than Southey, no poet has been a better man than he.

His *Life and Correspondence* (6 vols. 1849-50), by his younger son, the Rev. Outhbert Southey (1819-89), contains a delightful fragment of autobiography, written in 1820-25, but coming down only to 1789. It also gives hundreds of his letters to Cottle (q.v.), Landor, Lamb, William Taylor, Rackman, Ebenezer Elliott, Kirke White, Bernard Barton, Charlotte Brontë, Crabb Robinson, Sir Henry Taylor, &c. A *Selection* from these was edited by his son-in-law, the Rev. J. W. Warter (4 vols. 1856), who also issued Southey's *Commonplace Book* (4 vols. 1849-51); and a smaller selection by M. Fitzgerald (1912); his *Correspondence with Caroline Bowles* was ed. Dowden (1881). See the latter's *Southey* (1880); and memoirs by Sidney R. Thompson (1888), Dennis (new ed. 1895); and the *Early Life* by Haller (1917).

South Georgia, a mountainous island, in 54° 30' S. lat. and 36°—38° W. long., nearly 800 miles E. by S. of the Falkland Islands, of which it is a dependency. Discovered in 1675, it was taken possession of by Captain Cook in 1775; first crossed by Shackleton in his adventurous journey of 1916. The area is over 1000 sq. m., and there is a population of some 1300 (Norwegians), the island being the headquarters of several large whaling companies. The shore factories are lighted by electricity, and a number of the bays and promontories have lights. See Ferguson in *Trans. Roy. Soc. Edin.*, I. iv. (1915).

South Molton, a municipal borough of Devonshire, on the Mole, 10 miles ESE. of Bampton, with a fine Perpendicular church; pop. 2800.

South Orkneys, a group of small islands, about 780 miles SE. of the Falkland Islands and 200 miles E. of the South Shetlands (q.v.), were discovered by the English captain Powell in 1821. They are a dependency of the Falkland Islands.

South Pole. See ANTARCTICA, POLAR EXPLORATION.

Southport, a watering-place of Lancashire, near the Ribble estuary, 18 miles N. of Liverpool, 34 WN.W. of Manchester, and 19 S. by W. of Preston. The first house was a wooden inn built from a wreck here in 1792, on a sandy waste; and since about 1830 the place has grown more and more popular, enjoying as it does a mild climate, and having broad level sands. Southport is a spacious, conceived garden city, and has 100 acres of developed land seaward of the central promenade. This includes the Marine Parks, King's Gardens and Princes Park, with a modern amusement park and a marine lake; while Victoria Park (42 acres), Rotten Row with its famous herbaceous border, and Hesketh Park (30 acres) with astronomical and meteorological observatories, &c., almost adjoin the promenade. The total area of parks and gardens is about 300 acres. Lord Street, the principal thoroughfare, is a magnificent boulevard, in which open-air concerts are given during summer. The Municipal Buildings consist of Town Hall, Cambridge Hall (1874), Atkinson Public Library and Art Gallery (1878), Victoria Science and Art Schools (1887). The town has a fine suite of public baths (reconstructed 1926), municipal, technical, and other schools, an Opera House (1891), Winter Gardens and Botanic Gardens, and a large number of fine hotels and hydropathics. Nathaniel Hawthorne, then United States consul at Liverpool, describes Southport as it was in 1856 in vol. iii. of his *English Notebooks* (1870). It was made a municipal borough in 1867, a county borough in 1905, the boundary being extended in 1875 and 1912, and a parliamentary borough in 1918. Pop. (1921) 76,621.

South Sandwich Group. See SANDWICH GROUP.

Southsea, a south-eastern suburb of Portsmouth (q.v.), is a fashionable watering-place of recent growth, with two piers, a fine esplanade 2 miles long, a canoe lake, a common, a modernised castle of 1540, and other fortifications, barracks, &c.

South Sea Scheme (or BUBBLE) was originated by Harley (q.v.), Earl of Oxford, in 1711, with the view of restoring public credit and providing for the extinction of the floating national debt, which at that time amounted to £10,000,000. This debt was taken up by a number of eminent merchants, to whom the government agreed to guarantee for a certain period the annual payment of £600,000 (being 6 per cent. interest), a sum which was to be obtained by rendering permanent a number of import duties. The monopoly of the trade to the South Seas was also secured to these merchants, who were accordingly incorporated as the 'South Sea Company,' and at once rose to a high position in the mercantile world. The extravagant ideas then current respecting the riches of the South American continent were carefully fostered by the Company, who also spread the belief that Spain was prepared to admit them to a share of its South American trade. In 1717 the Company advanced to government other 5 millions. Their shares nevertheless rose day by day; and even when the outbreak of war with Spain in 1718 deprived the most sanguine of the slightest hope of sharing in the treasures of the South Seas, the Company continued to flourish. Far from being alarmed at the expected failure of the Mississippi Scheme (q.v.), the South

Sea Company believed sincerely in the feasibility of Law's scheme, and resolved to avoid what they considered as his errors. In the spring of 1720 they proposed to take upon themselves practically the whole national debt (at that time upwards of 30 millions), on being guaranteed 5 per cent. per annum for $7\frac{1}{2}$ years, at the end of which time the debt might be redeemed if the government chose, and the interest reduced to 4 per cent. The directors of the Bank of England, jealous of the prospective benefit and influence which would thus accrue to the South Sea Company, submitted to government a counter-proposal; but the more dazzling nature of their rivals' offer, in spite of protest from Walpole and other long-headed leaders, secured its acceptance by parliament. During the passing of their bill the Company's stock rose steadily to 330 on April 7, falling to 290 on the following day.

Up till this date the scheme had been honestly promoted; but now, seeing before them the prospect of speedily amassing abundant wealth, the directors seem to have thrown aside all scruples and made use of every effective means at their command for keeping up the factitious value of the stock. Their zealous endeavours were crowned with success; the £100 shares were quoted at 550 on May 28, and 890 on June 1. A mania of gambling seized the nation; preposterous companies of all kinds were floated, some of which were even prosecuted by the South Sea Company (under the 'Bubble Act') and exposed as swindling schemes. A general impression having by this time gained ground that the Company's stock had reached its maximum, so many holders rushed to realise that the price fell to 640 on June 3. Thereupon the directors sent agents to buy up eagerly; and on the evening of June 3, 750 was the quoted price. This and similar artifices were employed as required, and had the effect of ultimately raising the shares to 1000 in the beginning of August, when the chairman of the Company and some of the principal directors sold out. On this becoming known a wide-spread uneasiness seized the holders of stock, every one was eager to part with his shares, and on September 12 they fell to 400. The consternation of those who had been either unwilling or unable to part with their scrip was now extreme; many capitalists absconded, either to avoid ruinous bankruptcy or to secure their ill-gotten gains, and the government became seriously alarmed at the excited state of public feeling. Vain attempts were made to prevail on the Bank to come to the rescue by circulating some millions of Company's bonds.

The country was now wound up to a most alarming pitch of excitement; the punishment of the fraudulent directors was clamorously demanded; and parliament was hastily summoned (December 8) to deliberate on the best means of mitigating this great calamity. Both Houses, however, proved to be in as impetuous a mood as the public; and, in spite of the moderate counsels of Walpole, it was resolved to punish the authors of the national distresses, though hitherto no fraudulent acts had been proved against them. An examination of the proceedings of the Company was at once commenced, with results discreditable to the management; the private property of the directors was confiscated (to the amount of upwards of 2 millions) for the benefit of those who had suffered; seven millions due to the government were remitted; the Chancellor of the Exchequer, Aislabie, and other eminent persons were found guilty of having received bribes. The ruin wrought by the Bubble was incalculable, but the Company continued to exist and to trade till 1750, and had certain privileges till 1807. In 1863 its annuities were redeemed or converted into

government stock. The South Sea House in Threadneedle Street was the headquarters of the Company.

South Shetlands, a group of islands, some 750 miles SE. of the Falkland Islands, in 61° S. lat. Generally snow-covered, they are, like the South Orkneys (q.v.), an important whaling centre and a dependency of the Falklands.

South Shields, a seaport, county and parliamentary borough, and market-town of Durham, situated on the south bank of the Tyne at the mouth of that river, 9 miles ENE. of Newcastle-upon-Tyne. The name is said to have originated with the Tyne fishermen, who built sheds ('sheelds' or 'shields') on the river banks as a protection against the weather. On the Lawe, an eminence overlooking the river, the Romans had an important military station, approached from the south by the Rykniel Way. In later times it was called Caer Urfa, and it is said to have been the birthplace of King Oswin. Salt-pans were established here in 1489, and glass-works in 1619. The oldest part of the town extends for about two miles along the river-bank, and the streets, once narrow and dingy, have been widened and improved. The modern streets are wide and well-built, and South Shields is popular as a watering-place. The coast southward is very fine, the cliffs—magnesian limestone of the Permian system—being hollowed into picturesque caves. The principal public buildings are the town-hall, opened in 1910 (the old town-hall erected in 1768 stands in the centre of the market-place); the public library, news-room, and museum (1859); the marine school (opened 1869); the Theatre-Royal (1866); and the Ingham Infirmary (1873). At the east side of the town are the North and South Marine Parks, 45 acres in extent, divided by the pier parade. The Roman Remains Park at the Lawe contains many interesting relics of the Roman occupation. The south pier—a gigantic breakwater 5317 feet in length, protecting the harbour from the south-east gales, was begun in 1854, and completed in 1892. The harbour is lined with ship and boat yards, iron, glass, alkali, and rope works, paint and varnish manufactories, &c. Within the borough is the Tyne Dock, the property of the London and North-Eastern Railway, from which coal and coke are shipped to all parts of the globe. The dock, opened in 1859, covers an area of 50 acres. There are large collieries in the town. The first lifeboat was built at South Shields, and was used for the first time on 30th January 1790. A memorial to the inventors Wouldhave and Greathead has been erected on the pier parade. Near it is preserved the old 'Tyne' lifeboat which saved no less than 1068 lives. A life-brigade was established here in 1866. A steam-ferry for passengers and carriages plies between North and South Shields. South Shields was incorporated in 1850. Since 1832 it has returned one member to parliament. Pop. (1851) 28,974; (1891) 78,391; (1901) 96,267; (1921) 118,631.

Southwark, or 'The Borough,' on the Surrey side of the Thames, was annexed to the City of London (q.v.) in 1327, and is one of the metropolitan boroughs, with three members of parliament. Since 1904 it is the see of a bishop (previously of a suffragan bishop). In St Mary Overie's (now St Saviour's Cathedral) Gower was buried and King James I. of Scotland married. The polytechnic is well known. Pop. 184,000.

Southwell, a town of Nottinghamshire, since 1884 a cathedral city, on the ancient Ermine Street, 7 miles W. by S. of Newark and 12 NE. of Nottingham. A church was founded here by Paulinus about 630; but the stately cruciform minster, with its three towers, is wholly of post-Conquest

date, comprising Norman nave and transepts (1110), Early English choir (1250), and Early Decorated chapter-house (1300), the last with some beautiful carving. It measures 306 feet by 123 across the transepts, and the lantern tower is 105 feet high. A collegiate church until 1841, it became in 1884 the cathedral of a new diocese, including the counties of Notts and Derbyshire, taken from Lincoln and Lichfield; and in 1888 it was reopened after restoration. Its eagle lectern originally belonged to Newstead priory, having been fished out of the lake there about 1750. In the old 'Saracen's Head' Charles I. surrendered to the Scots commissioners (1646); Byron's mother occupied Burgence Manor House (1804-7); and there are picturesque ruins of the palace of the Archbishops of York (c. 1360; much altered and enlarged by Wolsey). The collegiate grammar-school was refounded in Henry VIII.'s time.

Southwell, ROBERT, poet and Jesuit martyr, was born about 1562, son of Richard Southwell of Horsham St Faith's in Norfolk. He was stolen from his cradle by a Gypsy woman, but soon recovered, and at fifteen was sent to Douai for his education. Challoner states that he studied also at Paris, but certain it is that he soon went to Rome, being received into the Society of Jesus on the festival of St Luke 1578. After a residence at Tournai he returned to Rome and distinguished himself so highly in the course of philosophy and theology as to be appointed prefect of the English college. He was ordained priest there in 1584, and three years later arrived in England in company with Father Garnet, who was also to earn the martyr's crown. Southwell was first sheltered by Loid Vaux, and next became domestic chaplain to the Countess of Arundel. Six years of quiet followed in which he fearlessly followed his vocation, and wrote his *Consolation for Catholics* as well as most of his poems. At length in 1592 he was betrayed into the hands of the authorities, was kept some weeks and infamously tortured many times in the house of an abandoned ruffian named Topcliffe, then transferred to the Gatehouse, and next to a noisome dungeon in the Tower. 'Though thirteen times most cruelly tortured,' writes Cecil, 'he cannot be induced to confess anything, not even the colour of the horse whereon on a certain day he rode.' After three years' close imprisonment he wrote to entreat the grace of an open trial to Cecil, who is said to have made the brutal reply that 'if he was in so much haste to be hanged he should have his desire.' He was transferred to Newgate, and, after three days' of confinement in *Limbo*, carried to Westminster for trial. The inevitable sentence followed, and on the 21st February 1595 he suffered at Tyburn, the victim of a barbarous statute, with all the high courage of the primitive martyrs. His prose writings are no longer interesting, but his poems retain their value. His longest poem is *Saint Peter's Complaint*: his most famous, *The Burning Babe*, a beautiful little piece of sanctified fancy, to have written which Ben Jonson told Drummond he would have been content to burn many of his poems. See Christobel Hood, *The Book of Robert Southwell* (1926).

South-west Africa, formerly German South-west Africa, a territory administered under League of Nations mandate by the Union of South Africa, the north-eastern ribbon-like extension to the Zambezi (the Caprivi Zipfel), being under the Bechuanaland Protectorate. The country is described under DAMARALAND, NAMAQUAS, OVAMPPOS. Largely desert, it has stock-raising lands in the east. Diamonds, copper, and vanadium are produced. A constitution was set up in 1925, with

a Legislative Assembly (two-thirds elected). Area, 322,393 sq. m., including 10,573 in the Caprivi Zipfel; pop. about 228,000, including 19,000 Europeans, nearly half Germans; capital Windhoek.

Southwold, a picturesque Suffolk watering-place, 41 miles N.E. of Ipswich. A municipal borough since 1489, it was almost destroyed by fire in 1659, but retained its fine Perpendicular church (1460), 144 feet long. In Southwold or Sole Bay a bloody but indecisive sea-fight was fought between the English and the Dutch on 28th May 1672. Pop. 3300.

Souvestre, ÉMILE, French novelist and playwright, was born at Morlaix, 15th April 1806, and, after some years of struggle, drifted into journalism, and at thirty went up to Paris, where he soon made some reputation by his charming sketches of Brittany and its people. These form the still delightful books, *Les Derniers Bretons* and *Foyer Breton*, his best work. Another deservedly popular book, *Un Philosophe sous les Toits*, was crowned by the Academy in 1851. Souvestre's plays were less successful than his stories, which, although didactic, are really seldom dull. He died in Paris, 5th July 1854. His *Causeries historiques et littéraires* (2 vols. 1854) are interesting.

Souza, MADAME DE, a charming French writer, was born in Paris, 14th May 1761, her maiden name Adélaïde-Marie-Émilie Filleul. Her parents died early, and she was brought up in a convent, from which she emerged only to marry the Comte de Flahaut, then fifty-seven, a union which was not happy. At the outbreak of the Revolution she found refuge, together with her only son, first in Germany, then in England, and here learned of her husband's execution at Arras (1793). For solace she turned to writing, and, in the midst of grief and poverty, wrote her first book, the fresh and delightful *Adèle de Senange* (Lond. 1794). After Thermidor she tried to return to France, but had to tarry a while at Hamburg, where she met the Marquis de Souza-Botelho (1758-1825), afterwards Portuguese minister at Paris, whom she married in 1802. The charm of her conversation and manners, her bright wit, and above all her goodness made her the queen of a group that numbered many of the most distinguished men in Paris. The Restoration brought her the great grief of long separation from her son, who had been aide-camp to Napoleon. She died in Paris, 16th April 1836. Later novels were *Émilie et Alphonse* (1799); *Charles et Marie* (1801), a delightful story, something in Fanny Burney's manner, and coloured throughout by English impressions; *Eugène de Rothelin* (1808), an exquisite piece of work, its hero a Grandison without insipidity; *Eugénie et Mathilde* (1811), her longest and best sustained story, in which we find close traces of her own history; and *La Comtesse de Fargy* (1822). Madame de Souza was a product of the best side of the 18th century, and she helps us to understand the politeness, the harmoniousness, the taste, the reticence—all that was noble and exquisite in the old régime. See Sainte-Beuve's *Portraits de Femmes*, and Baron de Maricourt's *Mme. de Souza et sa Famille* (1907).

Sova, ANTONÍN, Czech lyric poet, born in 1864.

Sovereign, in Politics, the person or body of persons in whom the supreme executive and legislative power of a state is vested. In limited monarchies sovereignty is in a qualified sense ascribed to the king, who, though the supreme magistrate, is not the sole legislator. A state in which the legislative authority is not trammelled by any foreign power is called a sovereign state. See GOVERNMENT; and for the 20s. piece, see POUND.

Soviet (*Russian* 'council'). See, for an explanation of the system, *SOCIALISM* (Vol. IX. p. 485); for its application, *RUSSIA* (Vol. VIII. p. 843). Soviets were also set up for a while in Bavaria and Hungary, and attempts have been made elsewhere (Argentina, Finland, &c.).

Sowerby, JAMES (1757-1822), was a native of Lambeth, who commenced as a portraitist and miniaturist, but now is remembered by his *English Botany, or Coloured Figures of all the Plants Natives of Great Britain* (36 vols. 1792-1807; new ed. 12 vols. 1863-86, the descriptions in the first by Sir J. E. Smith, M.D.). Other works dealt with Fungi, Conchology, and Mineralogy. Three sons who followed in their father's footsteps were James de Caille Sowerby (1787-1871), George Brettingham Sowerby (1788-1854), and Charles Edward Sowerby (1795-1842); and a son of the second was also George Brettingham Sowerby (1812-84), the author of many illustrated works on natural history.

Sowerby Bridge, a manufacturing town in the West Riding of Yorkshire, on the Calder, 3 miles SW. of Halifax. It has a town-hall (1857) and manufactures of worsted and cotton, oilcloth, chemicals, iron, &c. Tillotson was a native of the parish. Pop. 11,500.

Sowing-machines. Formerly sowing was always performed by scattering the seeds from the hand over the prepared surface of the soil. This mode, distinguished as *hand-sowing*, is still employed in many places, especially on smaller holdings and in garden husbandry. Formerly there were broadcast sowers which were carried in the hand, and in which the seed was scattered by a mechanism worked by a crank. These have been almost entirely superseded by machines of various kinds drawn by horses or tractors—the broadcast sowing-machine, the drilling-machine, and the dibbling-machine. The first is employed chiefly for cereals and grasses, the other two for any kind of seed.

Cereals.—As above mentioned, cereals may be sown broadcast, drilled, or dibbled. If the first method is to be adopted, the land receives what is called the seed-furrow, or, if rough, it gets a single stroke with the harrows, and the seed is then sown either by hand or by the broadcast-machine. This machine consists of a triangular frame with the apex to the front, supported on three wheels, and carrying a long wooden box of the form of a triangular prism, set with a flat side—the lid—uppermost. This box, which is placed at right angles to the line of draught, is furnished with a row of small holes at the bottom, about 7 inches apart; and a little above this row is placed a longitudinal spindle, carrying a set of hard circular brushes, one opposite each hole, and deriving a rotatory motion from the axle of the hind-wheels. The size of the apertures can be adjusted to the desired quantity of seed per acre by means of a movable plate outside provided with holes corresponding to those of the box. When the box is supplied with seed, and the machine set in motion, the grain drops through the holes, which are kept from clogging by the rapid rotation of the brushes. The box is made of such a length (16 to 20 feet) that 30 to 35 acres may be sown in a day. The seed is then covered by harrowing. This machine is much used in Scotland, being rather better suited to hilly and uneven surfaces, and, from its more rapid execution, to a climate which frequently interferes with agricultural operations. In England, where the climate is more favourable and the surface more level, the drilling-machine is the favourite. So it is now in certain parts of Scotland, where the amount of seed deposited by drilling has increased immensely. The

land is prepared for sowing by as complete pulverisation as possible, and its surface is made quite even by the harrow and roller. The drill (fig.), which in the arrangement of some of its essential

Corn-drill.

parts corresponds to the broadcast-machine, differs from it in being furnished with a set of coulters, which are hollowed behind to enclose the lower ends of a corresponding set of flexible steel tubes, whose upper ends are fixed opposite to the holes in the seed-box. By this machine a series of furrows of uniform depth are made by the coulters; into these furrows the seed is directed by means of the tubes. In the newest types sharp steel discs replace the 'knife' form of coulter and have the advantage of greatly reducing the draught. The modern drill-machine covers the seed most uniformly. The harrowing is generally completed before drilling begins. The spindle inside the seed-box is provided with grooved cylinders or pinions in place of brushes, and the seed-rows are generally made from 4 to 10 inches apart. The advantages of this machine over the broadcast sower consist in the greater regularity of deposition of the seed, which admits of hoeing and other cleaning operations during the early period of growth; in the uniform depth at which the seed is planted, so that none of it is lost by being buried, while it is all covered; in the protection of the operation from the disturbing influence of winds; in the saving of seed and greater yield of grain, it being often found that by drilling a fourth of the seed may be saved, and a better crop obtained; in the free access of sun and air during growth; and in the less liability of the crop to 'lodge' flat at the root. But it has one disadvantage: an ordinary drill cannot sow more than 10 to 12 acres per day, and employs more men and horses than the broadcast-machine. From 2½ to 3 bushels of seed per acre suffices with the drill, whereas from 3 to 4 is necessary with the broadcast-machine, and from 4 to 5 bushels with the hand. The great saving of seed and other advantages thus fully atone for the extra work involved by the drill.

The third method of machine-sowing, by dibbling, is employed chiefly on the light soils in the south of England, and now even there not generally, at least in the case of cereals, so that a minute description of the machines by which the operation is effected is unnecessary. Suffice it to mention that dibbling only requires about one-third of the seed which is necessary in drilling, and presents still greater opportunities for weeding and stirring the soil in the early stages of growth, but is attended with various important defects, and is more expensive. The maize- or corn-planter used in the United States is essentially a dibbling-machine, which drops small groups of seeds at definite intervals in the rows.

When a cereal crop is to be followed by grass the grass seeds are sown a few days, perhaps even a week or two, after the other crop by a broadcast-machine or by the hand.

Beans.—The sowing of this crop (see BEAN) is performed by means of the *bean-barrow*, a machine the same in structure as the drilling-machine for corn, but wanting the coulters, and having only

three tubes, through which the seeds fall. Peas are frequently sown along with beans, the latter acting as a support to the former, and the two together better preventing the growth of weeds. The hand is also sometimes adopted.

Turnips.—For this crop the ground must be more thoroughly cleaned and broken down than for any other; after which—if the drill-system is pursued—it is formed into drills from 26 to 29 inches apart, which are then supplied with manure, and covered with the drill-plough, splitting the original drills. The new ridges thus formed being directly above the manure, the seeds are sown on the top of each ridge by means of the *turnip-drill*. This machine has, instead of a seed-box of the ordinary form, two tin or tinned-iron barrels, placed on a spindle. Each cylinder has a row of holes round its middle circumference, the row being covered by a circular sliding collar of thin metal, perforated with corresponding holes. Each seed-box has its corresponding seed-tube and hollow coulter, as in the corn-drill; but the turnip-machine has in addition a roller in front of the coulters for compressing the crests of the ridges, and some machines have two light rollers attached behind which slightly compress the earth raised by the coulters and cover the seeds. In the southern counties of England a different form of machine is used, one which sows the seed in rows on the flat surface, and perhaps at the same time drops artificial manure, or waters the seed-bed, or both.

Sow-thistle (*Sonchus*), a genus of Compositæ (Cichorieæ). The Common Sow-thistle (*S. oleraceus*) abounds in Britain and in most parts of

Europe as a weed in gardens and cultivated fields. It is an annual plant, delighting in rich soils, grows to a height of 2 or 3 feet, with somewhat branching stem, and small yellow flowers in corymbs. The tender tops and leaves are much used in the north of Europe as greens. It is a favourite food with hares and rabbits, is eaten by swine, sheep, and goats, but not relished by cattle and horses. The Corn Sow-thistle (*S. arvensis*) is a perennial with large yellow flowers, frequent in cornfields in Britain and throughout great part of Europe. Nearly allied to the genus *Sonchus* is *Mulgedium*, to which belongs the Alpine Blue Sow-thistle (*M. alpinum*), whose beautiful blue flowers adorn some of the most inaccessible spots of Switzerland and of Scotland.

Sow-thistle (*Sonchus oleraceus*). allied to the genus *Sonchus* is *Mulgedium*,

to which belongs the Alpine Blue Sow-thistle (*M. alpinum*), whose beautiful blue flowers adorn some of the most inaccessible spots of Switzerland and of Scotland.

Soy, or **SOYA**, is a thick and piquant sauce made from Soy Beans (the seeds of the papilionaceous plants *Glycine Soja* and *G. hispida*). The seed is about 2 inches in length, and the full plant from 2 to 3 feet in height. It is a native of China, Japan, and the Moluccas, and is grown to an enormous extent in Manchuria, where twenty-five per cent. of the cultivated area is given up to it. Its importance as an article of European trade dates only from 1908, though it had long been more or less used. Not only are the beans, in various forms, an excellent food for cattle, but the

bean oil is used for burning, cooking, as a lubricant, as a substitute for butter, for making soap, high explosives, and the bean cake is a valuable fertiliser. Above all, by soaking, crushing, and boiling the beans and then adding sugar and phosphate of potash, a thick milky liquid is procured, which, when filtered, can be drunk fresh, or made into cheese, rich in casein. The beans can also be made into a sauce or used as a substitute for chocolate.

Soyer, ALEXIS (1809-58), was born at Meaux, was designed for the church, but became the most famous cook of his time. He had a post in Prince Polignac's kitchen in 1830, and was nearly murdered there by the revolutionists, but escaped to London, and was *chef* in the Reform Club (1837-50). He went to Ireland during the famine (1847), and in 1855 to the Crimea to reform the food-system. He wrote various books on cookery, and an account of his experiences in the Crimea. See the memoirs by Volant and Warren (1858).

Sozomen, a Constantinople lawyer (5th c.), born at Gaza, who wrote a church history largely based on Socrates. See CHURCH HISTORY.

Spa, a watering-place of Belgium, stands amid beautiful wooded hills 20 miles by rail S.E. of Liège. The principal buildings are the casino, bath-house, and similar institutions for the use of visitors. The springs, all chalybeate and alkaline, are cold, bright, and sparkling, and efficacious in anæmic complaints, heart diseases, &c. This water is exported to all quarters of the globe. Spa is famed for the manufacture of fancy wooden lacquered ware and of a liqueur. Pop. 8200. The virtue of the waters was known as early as the 14th century, and the place was particularly famous as a fashionable resort in the 16th and 18th centuries. Its public gaming-tables were suppressed in 1872. From March to November 1918 Spa was the seat of the German military headquarters on the west. From Spa the generic term for a watering-place or mineral baths is derived.

Spaccaforno, a town in the south-east corner of Sicily, 30 miles S.W. of Syracuse. In an adjoining valley are some remarkable 'Troglodyte' caves, ranged tier upon tier. Pop. 13,000.

Space. See PSYCHOLOGY; DIMENSION; and GEOMETRY.

Spade-husbandry. The operation of digging is performed with a spade, or pronged fork, or with a steam-digger. The spade or fork is thrust in with the foot, and the mass of earth is first loosened by the lever-power of the handle, then lifted and inverted. When this operation is performed in spring or summer, the ground should be dry, so as to obtain pulverisation as easily and to as great extent as possible. In stronger soils, which are dug in autumn, a little moisture is desirable, as the land lies fallow, and the frosts of winter afterwards pulverise and reduce it to a proper degree for receiving the crops in spring. Digging by hand is mainly confined to the cultivation of gardens and small 'crofts,' for, though a most efficient means of cultivating the soil, it is too expensive for field-crops. It is resorted to, however, for digging over or trenching land which has been in timber or full of stones or boulders. Formerly the spade was the only implement used for digging, but steel forks are now more largely used, being lighter and more easily driven into the soil. Besides preparing the land for plants, the spade and the fork, chiefly the latter, are used for taking crops, such as potatoes and carrots, out of the ground. For the important subject of spade-husbandry and cottage-farming as an economic and social problem, see PEASANT PROPRIETORSHIP.

Spadix. See SPATHE.

Spagnoletto. See RIBERA.

Spagnuoli. See MANTUANUS.

Spahi, the Turkish form of the Persian word *Spahi* (from which we get Sepoy), was the term for the irregular cavalry of the Turkish armies before 1836. From the old Turkish troops in Barbary, the native Algerian cavalry in the French service are still named *spahis*.

Spain (Span. *España*) occupies the larger part of the south-western peninsula of Europe, and attains in Cape Tarifa the most southerly point of the whole continent. It lies between 43° 45' and 36° 1' N. lat., and between 3° 20' E. and 9° 32' W. long. It is bounded by the Bay of Biscay and the Pyrenees, by the Mediterranean, and by the Atlantic and by Portugal. From Fuenterrabia in the north to Tarifa in the south is 560, from Cape Finisterre in the north-west to Cape Creus in the north-east is 650 miles. The area of continental Spain is 190,050 sq. m., and the population in 1920 was 20,541,824. In 1834 the Balearic and Canary Isles were, however, included in the country, which was then divided into forty-nine provinces, but the names of the fourteen more ancient kingdoms and provinces are still in use (see table). Ceuta in northern Africa is included in the province of Cádiz.

For a moment in the 16th century Spain was the most important country in Europe; but its population of 10 millions, unequal to the drain caused by constant warfare, emigration, expulsion of some of the inhabitants of the peninsula, and above all by adverse economic and industrial conditions, fell to 6 millions in the 17th century. The numbers then slowly rose: (1768) 9,307,804; (1797) 10,541,221; (1857) 15,464,340; (1900) 18,607,674. The town and industrial population has augmented in a greater ratio than the rural and agricultural, but emigration, especially to the eastern South American states and to Mexico, has been regular. In 1920 there were twenty-seven towns with populations greater than 50,000; the most important were Madrid, the capital (750,896), Barcelona (710,335), Valencia (251,486), Seville (*Sevilla*, 205,529), Málaga, (150,584), Saragossa (*Zaragoza*, 141,350), Murcia (141,175), Bilbao (128,819), and Granada (103,368). The most densely populated provinces are those of Vizcaya, Barcelona, Guipúzcoa, Madrid, and Pontevedra. The Spanish nation is composed of a number of national groups with different characteristics (and also, in some cases, with different political aspirations); the Andalusian is noted for his insouciance; the Castilian for his pride; the Galician for his laboriousness; the Aragonese for his indolence. The most progressive and independent province is Catalonia, a pre-eminence accounted for not merely by the favorable climate and the irrigation work done by the Moors, but also by the energetic character of the people. There are about 400,000 Basques (q.v.) in Spain, some 50,000 gipsies, and some Jews. Of the former great colonial empire nothing now remains save a few possessions in Africa, of which only the municipality of Melilla (50,170), the district of Bata or Río Muni (area, 10,000 sq. m.; pop. 68,024), and the islands of Elobey (27,592) and Fernando Po (20,650) are of importance. The huge district of Río de Oro (100,000 sq. m.) has only a few hundred inhabitants. The situation in the Spanish zone of Morocco (q.v.; area about 8000 sq. m.; pop. about 600,000) and in Ijui (q.v.; area about 1000 sq. m.; pop. about 20,000) remains uncertain.

Configuration.—The coast-line is estimated at 1317 miles, of which 712 belong to the Mediterranean and 605 to the Atlantic. Spain has thus but 1 mile of coast-line to 145 sq. miles of area, while Italy has 1 to 40 and Greece 1 to 7. The shore of the Bay of Biscay presents an almost unbroken wall of mountain and rock, but in the north-west and west appears the most southerly prolongation of the fiord or firth system of Norway, western Scotland, and Ireland, forming as usual fine harbours—Ferrol, Coruña, Vigo, &c. Portugal indents a frontier of nearly 400 miles; to the south, from Portugal to Gibraltar, the Atlantic coast is low. Cádiz is here the chief harbour. The southern Mediterranean shore is rocky, backed up by the huge mass of the Sierra Nevada and its prolongations to Cape Gata. Málaga and Almería are the chief harbours here; in the south-east and east are the naval arsenal of Cartagena and the commercial ports of Valencia and Barcelona and others. Though almost a peninsula, this uniform character of the coast-line and the great elevation of its central plateau give Spain a more continental character in its extreme range of temperature than any of the other peninsulas of Europe. The greater part of its surface consists of a plateau of between 2000 and 3000 feet above the sea-level, traversed by loftier ranges. On the east the plateau is buttressed by chains which descend rapidly to the Mediterranean. On the north the Sierra de Moncayo and its neighbours rise sharply from the valley of the Ebro; the Sierra Morena on the south is of inferior elevation; the western ranges

run into the frontier of Portugal, and lose themselves in the Atlantic. Outside the plateau lie the highest summits of the whole country, the Pico de Mulhacén or Muley Hacén (11,420 feet) in the Sierra Nevada (q.v.) and the Pic de Néthou (11,170) in the Pyrenees (q.v.), which are continued along the north coast as the Catabrian Mountains. The plateau itself is traversed by four mountain-ranges—the Iberian (including Moncayo), which separates the valley of the Ebro from that of the Douro (*Duero*); the Guadarrama Range, which divides the Douro from the basin of the Tagus (*Tago*); the Sierra de Toledo, which forms the watershed between the Tagus and the Guadiana; while the southern buttress, the Sierra Morena, forms the northern wall of the valley of the Guadalquivir. The whole plateau has a general slight inclination from east or north-east to south-west, and hence all the considerable rivers of Spain except the Ebro flow westward to the Atlantic. The general elevation of the plateau conceals the real height of its mountains and passes; thus, the highest point of the railway from the north to Madrid is about 60 feet higher than the tunnel of Mont Cenis, and that of the old coach-road through the Guadarrama is 300 feet higher still.

Geology.—A mass of granitic, Cambrian, and Silurian rocks extends from Galicia south-east to the valley of the Guadalquivir. The Carboniferous formation occupies the north and south-west corners of the great plateau. The valley of the Ebro is a trough of Secondary rocks extending from the Bay of Biscay to the Mediterranean; another band of Secondary rocks forms the region of Andalusia south of the Guadalquivir; the Upper Cretaceous formation stretches from the basin of the Ebro to the granite of the Guadarrama and to the east of Madrid; these older formations are overlaid by Tertiary, Eocene and Miocene, marine and fresh-water deposits. The visible surface of Spain consists of 37 per cent. of crystalline and Palaeozoic rocks, 34 per cent. of Tertiary, 19 of Secondary rocks, and 10 per cent. of Quaternary deposits. The remains of undoubted volcanoes are found at Olot in Catalonia, at Cabo de Gata in the south-east, and at Cuidad Real in La Mancha. To the frequency of older igneous action, and to the fractured conditions of the later rocks, is perhaps due the great mineral wealth of Spain.

Climate.—The configuration of the country renders the climate very varied. In Estremadura and New Castile the winters are bitterly cold, and the summers arid and hot. The northern provinces have an equable climate, while Andalusia is subtropical. In parts of the north-west the rainfall is among the heaviest in Europe. In the east and south-east occasionally no rain falls in the whole year. The rainfall in the Western Pyrenees is very great, yet on the northern slope of the valley of the Ebro there are districts almost rainless. The western side of the great plateau, speaking generally, is more humid and much colder than the eastern, where irrigation is necessary for successful cultivation. With this difference in climate goes a corresponding difference in flora. The high table-land in the centre is characterised by low shrubs and an absence of trees; Catalonia and Valencia resemble the south of France as regards vegetation, and Andalusia resembles North Africa; in the north there are meadows, both for pasture and agriculture, and forests. The wolf, lynx, fox, genet, wild-boar, badger, ibex, &c., and the eagle, vulture, snipe, and various forms of wild-fowl are found in Spain.

Agriculture.—About 44 per cent. of the total area of the country is arable, about 48 per cent. pastures and mountains, while about 8 per cent. is classed as 'unproductive.' Of the 'productive'

area, however, much is not under direct or regular cultivation, but machinery is gradually superseding primitive methods of farming, and progress is being made with irrigation, notably in Alicante. About three-quarters of the working population is occupied with agriculture. Wheat and barley to the extent of 11 and 4½ million acres respectively, are the principal grains; oats, rye, maize, and beans and other vegetables are also grown on the plains of León and Old and New Castile. In the south, beet-sugar and rice are cultivated to a certain extent. Other products from the south are cotton, esparto grass, and the mulberry. These are devoted to olives and to vines about 4 and 3½ million acres respectively, the wines of Alicante, Málaga, and Jerez or Xeres (sherry) being especially famous. The Spanish olive-crop, mostly from Andalusia (*Andalucía*), is one of the most important in the world, while vines are grown all over the country. Dates, figs, apples, oranges, &c., are plentiful in different parts. There are still large numbers of sheep, which roam over central Spain, but the famous merino breed has rather deteriorated, while goats, mules, and asses are the most common domestic animals. Cattle are reared in Galicia, but the bulls for the Bull-fights (q.v.) generally come from the south.

Mining and Industries.—Minerals exist in Spain both in great variety and in large amount, but at present mining takes place only close to the sea or in the basin of the Guadalquivir; there is no doubt that further developments are possible. About 6 million metric tons of coal are produced annually, mostly from Asturias, but also from León, Valencia, and western Andalusia. Iron and copper are found in western Andalusia, and iron also in the Basque country; zinc and lead in Murcia, and zinc also in the Basque country; quick-silver in La Mancha. Tin, salt, manganese, silver, and mercury are also mined. About 140,000 workers are employed in connection with the mining industries.

Catalonia, with its capital Barcelona, is the seat of the manufacturing industries of Spain, the cotton-mills there having some 2 million spindles. There are also woollen and paper mills, manufactories of silk and leather, glass-making, preparing of wine and fruit (especially for foreign consumption), but metal industries, foundries, &c. (in connection with the coal and iron found in the vicinity), are also located at Oviedo in Asturias and Bilbao in the Basque country, and there are various manufactories at Cádiz. Fishing (*sardines*, *cod*) is important, and there is some shipbuilding.

Trade and Commerce.—Imports have generally exceeded exports, and since 1921 the former have averaged per annum 117 million sterling in value, and the latter 64 million sterling. The principal imports are food-stuffs (grain, &c.), tobacco, minerals (glassware, &c.), machinery, chemicals, iron and steel manufactures, raw and manufactured cotton, and the principal exports are wine, fresh and dried fruit, olive-oil, vegetables, timber, and mineral ores. Most of the trade is done with Great Britain (to the extent of one-fifth), France, the United States, and the Argentine. The principal ports are Barcelona, Bilbao, and Cádiz, but the Spanish merchant marine chiefly confines itself to coastal (and not to ocean) trade. In the kingdom there are altogether over 9350 miles of railway belonging to private companies, but legislation in 1925 allows for a certain amount of state control. The gauge of the principal lines differs from that of France for strategical reasons. In 1926 an ambitious (but very necessary) programme was drawn up for extension and electrification, chiefly in the north. Mainly owing to the steepness of the gradients, it is not expected that the Pyrenean

tunnels now under construction (the Sompur and Puymorens tunnels, connecting Pau with Saragossa and Foix with Vich) will affect international traffic to any marked extent. Owing to the mountainous character of much of Spain, motor transport would seem to be of great importance and value.

Finance.—Since the Great War, the Budget has been balanced at about £120,000,000 sterling per annum. The revenue is obtained chiefly from taxes on real estate and on movables, from the customs, post-office, and the state monopolies (tobacco, lotteries, &c.). The expenditure is devoted principally to interest on the national debt (to the extent of one-quarter), to the army (especially with reference to Morocco), and to the public works. The national debt amounts to some £680,000,000 sterling. The wealth of the country has increased considerably during the 20th century, but much of the capital invested in Spanish concerns, such as the railways, comes from abroad.

Constitution.—The government is that of a hereditary monarchy, based on the constitution of 1876. The parliament (*Cortes*) consists of a senate (360 members) and congress (417 members) of equal authority. Half of the senate sit by their own right (royal princes, grandees with a certain income, high military, civil, and ecclesiastical dignitaries) or are nominated by the crown, while the other half are elected by the corporations of state, to be renewed by one half every five years. The congress is elected for five years by universal male suffrage (over 25 years of age), in proportion of one deputy to every 50,000 inhabitants, and every elector is eligible for candidature. Senators and deputies are paid. The monarch and each of the chambers can take the initiative in legislation, while the executive is vested under the monarch in a council of ministers. Every commune has its own elected council (*Ayuntamiento*), half elected every two years, with its president and executive functionary (*Alcalde*), and each province has a governor and its own elected assembly (*Diputación Provincial*). Local government, for which there is universal male and female suffrage (over 23 years of age), is largely independent of the central authority. The principal courts of justice are the Supreme High Court, the fifteen Divisional High Courts, and the fifty Provincial High Courts. The Dictator, Primo de Rivera (q.v.), suppressed temporarily much of the constitution.

Religion and Education.—Practically the whole of the population belongs to the Roman Catholic faith, but there is freedom of worship for all. There are 9 archbishoprics (the primacy being Toledo), with 47 suffragan sees and 66 cathedrals. The church is supported by the state. Many religious orders are established in Spain (though theoretically against the concordat of 1851), and there are nearly 10,000 monks and 40,000 nuns, many of whom devote themselves to education.

According to the 1920 census about 50 per cent. of the total population is illiterate (in 1860 the proportion was 75 per cent.), despite the fact that since 1857 primary education has been compulsory. With better remuneration, the teaching profession, however, has now considerably improved. The state supports the primary and partly controls the private and the secondary schools (*Institutos*). There are various ecclesiastical schools and many schools of art, industry, commerce. There are eleven universities—Barcelona, Granada, Madrid, Murcia, Oviedo, Salamanca, Santiago, Saragossa, Seville, Valencia, Valladolid—attended by some 25,000 students.

Defence.—Military service is compulsory for all over the age of 21, two years being spent in the active army and sixteen years in the other stand-

ings. The army of continental Spain is divided into eight divisions, each under a captain-general. The peace effective of the active army is about 150,000 of all ranks, and of the second line about 90,000, but the Moroccan situation after the Great War gave rise to further mobilisation. The war strength can be brought up to 750,000 at once. The personnel of the navy amounts to about 16,000 of all ranks.

See separate articles on the provinces and the principal towns of Spain. For the Topography see books by Webster (1882, in Eng.), Bazin (1895, in Fr.), Ceroeda (1922, in Span.), Hielscher (1922, in Eng.); also Åberg, *Lacivilisation énéolithique* (1921), and Mayer, *Alt-Spanien* (1922). For Travels and General Description, Borrow, *The Bible in Spain*, and A. J. C. Hare, *Wanderings in Spain*, also books, all in English, by Marden (1909), Calvert (1911), Howells (1913), Dickinson (1914), Chapman and Buck (1920), Newell (1922), Bell (1924); books on the cathedrals by Gade (1911), and on the cities by Symons (1918); and the admirable *Spanish Series* of monographs (ed. Calvert, 1906 *et seq.*), profusely illustrated, on various aspects of Spanish life, painting, architecture, &c. For Social Life, Eliot, *Old Court Life in Spain* (1893); Morel-Fatio, *Études* (1890-1904); Altamira, *Psicología del pueblo español* (1902); and books in English by Higgin (1902), Williams (1902), Havelock Ellis (1908), Tyler, (1909), Shaw (1910). For Economics and Politics, Guyot, *L'évolution politique et sociale en Espagne* (1899); books in English by Ward (1911), Deakin (1924), in French by Marvaud (1910), Jolclerc (1921), in Spanish by Muiñana (1915), Graell (1917). For the Law and Constitution, books in Spanish by Calvo Márcos (1893), Barrio y Mier (1894), Gay (1905), and in German by Poseda (1914). For Spanish painting, see ART.

HISTORY.—Spain (*Spania, Hispania, Iberia*) of the Greeks and Romans), from its position as the south-west peninsula of Europe, beyond which was the ocean only, early became a very eddy of tribes and races. Palaeanthropic man was succeeded at the end of the Mousterian stage by Neanthropic races from Africa. Of these the Pyrenean race (perhaps Cro-Magnon) in the north seems to be represented to-day by the Basques of Spain. The Eurafian, still traceable in the present population, brought the Caspian culture which developed into Aurignacian. North Spain is rich in art works of the Upper Palaeolithic stages (see ART). Whatever his relation to the Cro-Magnon race, Iberian or Mediterranean man can be traced back to the transition between Palaeolithic and Neolithic. To this dark long-headed race the prevailing type of present-day Spaniard belongs. It occupied nearly the whole of Spain and the south of France before the Roman conquest. Overlying these Iberian tribes are probably two invasions of Celtic peoples; the earlier mingled with the Iberians, and formed the Celtiberian tribes of central and western Spain; the later has left the more purely Celtic names in the north and north-west. There was probably never any Iberian nation—only a congeries of tribes of the same race like that of the North American Indians, but in a higher state of civilisation—a civilisation excelling that of contemporaneous Gaul or the more purely Celtic tribes to the north. Omitting traces left by mere traders, such as the supposed 'prospectors,' the Phoenicians on the south and south-west, the Egyptians on the east, Greeks from Massilia on the north-east, the first power which seriously attempted to occupy Spain was Carthage (q.v.). The Carthaginians had probably succeeded to the commercial enterprises of their mother-country Phoenicia; but it was not until they had retired baffled from Sicily that the occupation of Spain was seriously begun. Hamilcar, first of the great line of Carthaginian generals, opened the conquest in 238 B.C. (see CARTHAGE, HAMILCAR, HANNIBAL). Here again they were met and thwarted by the Romans (see ROME, HANNIBAL, SCIPIO). It then became the

task of the Romans to conquer Spain. In subjugating the Iberian and Celtiberian tribes of Spain they found far greater difficulty than with any more purely Celtic race. Spain early showed her tenacity of resistance. The sieges of Saguntum, Numantia, Clunia are memorable in history. Even when conquest seemed assured Viriathus (147-140 B.C.), probably a native, and Sertorius, a Sabine leader (83-72 B.C.), tried the capacity of the best generals of Rome. It was in Spain too that the final issue between Cæsar and the Pompeians was fought out at Munda. Spain was not completely brought under Roman rule till the time of Augustus. Once subdued, it became thoroughly Roman. The impress of Rome has been deeper on the language, manners, and religion of Spain than on those of any other country. Under the Romans Spain was divided first into two provinces—Nearer and Farther Spain: in the time of Augustus these became three—Bætica, embracing nearly the modern Andalusia; Lusitania, Portugal with some of the western Spanish provinces; and Tarraconensis, comprising the remainder of the country. Local rule and customs and speech were, however, not wholly obliterated in the varied Municipia and Republicæ. Celtiberian coinage continued contemporaneously with that of Rome, and for probably 200 years after Augustus. All the great arts and works of Roman civilisation flourished. Latin was the language of the educated classes, and Spain furnished a large contingent of authors to the silver age—Martial, Seneca, Quintilian, Lucan, Silius Italicus, Columella, Pomponius Mela. Trajan was a Spaniard. Some of Spain's greatest cities still bear Latin names—Legio (León), Emerita Augusta (Mérida), Cæsar Augusta (Zaragoza or Saragossa), Pompeiopolis (Pamplona). During Roman rule Christianity was introduced into Spain, and rapidly spread. In 325 A.D., at the Council of Nicea, Hosius of Córdoba was the greatest name in the west, overshadowing that of the bishop of Rome. Prudentius (338-405), almost the first Latin Christian poet, was a native of northern Spain. Two centuries later (560-636) Isidore, bishop of Seville, was the most learned writer of the west.

With all western Europe Spain felt the effects of the downfall of the Roman empire. The native Spanish legionaries were serving in all parts of the empire; barely two foreign legions garrisoned the whole of Spain. Thus, when the Suevi, Alans, Vandals (c. 409), Visigoths (414; see GOTHs) invaded Spain, the country, which had cost the Romans two centuries to subdue, had little means of resistance. The Suevi established themselves in Galicia and Lusitania, the Vandals penetrated farther south, and gave their name to (V)andalusia; thence in 429 they crossed to Africa. The Visigoths brought with them more than a tinge of Roman civilisation. Though both Visigoths and Vandals were nominally Christians, their Arian heresy placed them in opposition to the native bishops, the most ardent defenders of the Nicene faith. For some time Spain was only a province of a larger Visigothic kingdom. Theudis (573) was the first Visigothic king who fixed his court in Spain. It was not till the reign of Leovigild (584) that the Suevi were definitely dispossessed, and not till the reign of Suintilla (624) that the Byzantine Romans were finally expelled from the east coast; and even to the end they retained the Straits of Gibraltar and a few towns in southern Portugal; and some native tribes in the Orospeña Mountains preserved their independence. The abjuration of Arianism by the sons of Leovigild strengthened the church at the expense of the monarchy. The bishops were supreme in the councils of Toledo, which were also the chief councils of the state. The Jews, unmolested by the Arians, were now persecuted and rendered

hostile. They intrigued with the Mohammedan Arabs, who had conquered North Africa and crushed out Christianity. Their assistance and that of the count of the Roman possessions in the straits enabled Tarik to land at Tarifa; and the Gothic monarchy was destroyed at the battle of the Guadalete (711), where fell also Roderic, last of the Gothic kings. The chief mark left by the Goths in Spain was in legislation; first in the *Lex Romana Visigothorum*, then in the *Fuero Juzgo* or *Forum Judicum*. The tradition of a conquering caste and the events of the reconquest made the Spanish aristocracy look on the Visigoths as the English gentry do on the Normans; otherwise their influence has been exaggerated. The few remains of art are copies of Byzantine models. Of literature not a trace remains.

The Moors in Spain.—Seldom has there been so rapid a conquest as that of Spain by the Arabs and Moors. In 714 they had gained the whole of Spain except the north and north-west. In 719 they had added the Narbonnaise to their dominions; in 732 they reached their extreme northern limit when defeated by Charles Martel at the battle of Tours. The Arabs and Moors were divided by racial, tribal, sectarian, and dynastic differences. The old quarrels which had existed in Arabia before the time of Mohammed broke out again in Spain as soon as the first enthusiasm of conquest had subsided. Arabs and Berbers of North Africa were ever at strife; the feuds between the sects of Islam raged bitterly in Spain, and the claims of rival dynasties—e.g. the Abbasides and Ommiades—weakened the common cause. Whenever the Moors were united the progress of the reconquest was checked; the Christians gained ground when division and disunion spread among the invaders. The final expulsion was delayed for centuries through the civil strife of the Christian kingdoms. The rule of the early emirs was by no means harsh; a Gothic chief Theudoric preserved an independent Christian kingdom, Todmir, in Valencia and the neighbouring provinces. The Jews were treated almost as equals, the Christian religion was tolerated to the Mozarabes (see MORISCOS). There were differences in the several provinces, but at Córdoba only, which became the capital of the western khalifate (see KHALIF, MOORS), was any persistent persecution carried on. Under Abderrahman I., the heir of the Ommiades, and his successors the Arab rule in Spain attained its highest glories. He (756) and his son Hakam I. (796) made Córdoba the finest city in the west; its mosque (786-796) is still one of the grandest remains of Arabic architecture. No Christian people in the west was then capable of such work. The greatest chief of this period was Almanzor, who forced back the tide of Christian conquest and penetrated to Compostela in Galicia (997); but all his conquests were lost at Catalañazor (1002). Many Moorish names survive in Spanish topography. The origin of the various Spanish kingdoms of the reconquest is obscure. Pelayo, said to be of Gothic or mixed Roman blood, began the reconquest at Covadonga in 718. A little later a distinct organised resistance commenced in Navarre and in Aragon. The counts of Barcelona established themselves in the Spanish March which dated from Charlemagne (q.v.) and Louis. The most important of these kingdoms was that of Asturias. Galicia on the west was soon annexed to it, then León to the south. Alfonso I. (739-756) had already overrun the country as far as the Mondego and the Sierra de Guadarrama. Alfonso II. (791-842), the ally of Charlemagne, pushed his raids as far as Lisbon, and founded in the north the cities of Compostela and Oviedo. Alfonso III. (866-909) removed the capital to León, and reached in one ex-

pedition the Sierra Morena. The unwise division of his dominions among his sons retarded the advance for a time. After the battle of Catalañazor the Christian frontier stretched from the Tagus to Tudela on the Ebro; and Castile (the land of frontier castles), which had been governed from 932 by semi-independent counts, rose into a new kingdom. From this period date the constitutional liberties of Spain. The councils summoned by the king continued those of Toledo, and were as much political as ecclesiastical: assemblies of the nobles and magnates to settle the succession or election of kings were held in 931 and 933; but the first more general Cortes was that of León, 1020. In it was established the right of *behetría*—i.e. of changing lords, which in Spain prevented many of the worst feudal abuses, but encouraged civil war. Many of the fueros were now granted in order to attract defenders to towns reconquered and denuded of inhabitants (see FUERO).

After the death of Bermudo III. (1037) the crowns of León and Castile were united under Ferdinand the Great; his son, Alfonso VI., by his capture of Toledo (1085) made the Christian power predominate. In spite of a defeat at Zalacca (1086) and at Uclés (1108), Toledo was never reconquered by the infidels, and the Guadiana instead of the Tagus was now the Christian boundary. To the reign of Alfonso VI. belongs the story of the Cid (q.v.), of his strange career as ally alternately of Moor and Christian, of his occupation of Valencia from 1096 to 1102. Henry of Burgundy founded the country or kingdom of Portugal in 1095 (see PORTUGAL). Alfonso VII. lost the battle of Alarcos (1194), but the great victory of Navas de Tolosa (1212), under the allied kings of Castile, Navarre, and Aragon, broke entirely the power of the Almohades, and made New Castile secure. The separation of León from Castile (1157–1230) weakened for a time the Christian forces. Under St Ferdinand, the grandson of Alfonso IX., the crowns of León and Castile were finally united. He wrested Córdoba from the Moors (1236), Jaén (1246), Seville (1247), Jérez and Cádiz (1250), Granada became a tributary kingdom, and the line of the Guadalquivir was held by the military orders of Calatrava, Santiago, and Alcántara. Ferdinand died in 1252. Navarre (q.v.) by the succession of the line of Champagne had become almost a French kingdom. To the east Saragossa had been taken in 1118. Valencia had been lost for a time, but first Majorca and the Balearic Isles (1228), then Valencia (1237) fell before the arms of Jaime I. of Aragon, and Murcia was won for Castile (1244).

In constitutional progress Navarre and Aragon kept pace with Castile. Each had its separate Cortes, with three estates in Navarre and four in Aragon, and its own code of laws. Castile used the *Fuero Juzgo* and the *Fuero Real*, limited by local fueros; in Navarre and Aragon the fuero was supreme. Catalonia had her *usages*. The *Siete Partidas* of Alfonso X. did not become law till 1384. In ecclesiastical matters Spain had become more closely papal; the Roman rite had superseded the Isidorian or Mozarabic after the taking of Toledo; the finest of the cathedrals of Spain—León, Burgos, Toledo, &c.—date from this period. Christian Spain had increased immensely in wealth, yet it took nearly two and a half centuries to destroy the remains of Moorish power. The period between the death of St Ferdinand and the accession of Isabella of Castile (1468) was one of trouble and almost constant civil war. The influence of the Moors on Christians was in some ways more marked than before. Alfonso the Wise (1252–84) in his court at Toledo adopted the best of Moorish science and literature, and the philosophy and art

which they had acquired from the Greeks and Byzantines, and henceforth Spanish was not inferior to Moorish civilisation. A century later the Moorish influence was almost wholly ill in the Sevilian court of Pedro the Cruel, the ally of the Black Prince, whose whole career and death by his brother's hand was more like that of an oriental sultan than of a western monarch. The troubles of Castile arose from disputed successions, from long minorities, from the claim of the nobles, even those of the royal family, to transfer their allegiance to any sovereign they might choose (*behetría*). The Infantes de la Cerda and Henry of Trastamare acted alternately as subjects of Castile, Aragon, or France, or entered into alliance with the Moors, as might serve their private interests. The only trustworthy allies of the crown were the burghers and the clergy, but the rivalry of the cities made their allegiance doubtful. At the death of Henry IV. (1474) the crown of Castile was left with two female claimants, his daughter Juana (the Beltranaja) and his sister Isabella. The election of the former meant union with Portugal; by the marriage of Isabella with Ferdinand of Aragon her election united Castile and Aragon. Under a series of strong monarchs, whose authority was limited by a powerful aristocracy, Aragon had become a strong Mediterranean power—to the Balearic Isles had been nominally added Corsica and Sardinia, more really Sicily and Naples, with claims on Northern Italy; these claims and possessions after the union led to the waste of Spanish blood and treasure for centuries, without any corresponding advantages. The conquests from the Moors in this period were few but important—Tarifa (1292), to recover which the African Moors made their final effort of conquest; their defeat on the Salado (1340) entailed the loss of Algeciras in 1344; and Gibraltar, which they had recovered after 1309, became Spanish in 1462. Henceforth the Moors existed in the Peninsula on sufferance only, while the Christians were gathering their forces for the final blow.

Small as were the resources left to the Moors, they were weakened still further by dissensions in the ruling families. Boabdil, the last king of Granada, would have made terms with Castile; his uncle, Muley Hacen of Málaga, and his nephew, El Zagal, opposed a strenuous resistance. Alhama was taken 1482, Ronda 1485, Málaga 1487, Baza 1488, and the Spanish sovereigns with an army of 100,000 men sat down to the siege of Granada in 1491. January 2, 1492, the city surrendered; October 12, 1492, Columbus discovered America; in 1512, after the death of Isabella, Ferdinand wrested Spanish Navarre from its Gascon kings.

Henceforth the history of Spain is no longer exclusively Spanish, but also European. The whole of the Peninsula except Portugal was united under one rule, but true political unity was very far from having been attained. Aragon and Navarre still preserved their separate Cortes, privileges, and regnal titles; the Basque Provinces continued almost a republic under a Spanish suzerain. In Castile, however, the royal power had been greatly strengthened; the fatal mistake of the *procuradores* in accepting royal pay under Pedro the Cruel ensured the ultimate subservience of the Cortes. The masterpieces of the great military orders had become the gift of the crown in 1476, and in 1513 Pope Hadrian VI. annexed them permanently to it; the *Hernandades* (q.v.), or ancient associations, first of the bishops, afterwards of civil bodies, for defence of their rights and for the suppression of disorder, became a powerful governmental police; the Inquisition, first employed on a large scale against the Albigenses by the Domini-

cans in 1248, had been remodelled (1478) to the profit of the crown. But the increased power of the monarchy lay chiefly in the condition of the conquered provinces. Their incorporation was an immense gain to the country, but it gave the king a basis for despotism, and a standing force where-with he could crush any revolt in the north. The still advancing wave of Mohammedan power was not finally rolled back until the battle of Lepanto (1571) and the raising of the siege of Vienna (1683). The Moors of Barbary were still able to harass Spain and seriously to check her trade; but the most fatal legacy of the Moors was the fact that Spain had won her glory as champion of Christianity against Islam in the peninsula, and continuing this rôle she wasted all her resources, and failed, as champion of Roman Catholicism against Protestantism in Europe.

On the death of Isabella her eldest daughter Joana, who had been married to Philip, son of the Archduke Maximilian, sovereign of the Netherlands, succeeded, jointly with her husband, to Castile. Ferdinand retired to Aragon. Philip died in 1506, and Ferdinand resumed the government of Castile as regent for his daughter, who was incapacitated by insanity. Ten years afterwards he died, leaving all his kingdoms to Juana, with her son Charles as regent. Till the arrival of Charles Spain was really governed by Archbishop Ximenez (q.v.), whose work in the interest of the crown was almost as important in Spain as that of Richelieu later in France; his intolerance to the conquered Moors brought on revolts, and all the subsequent troubles with the Moriscos were the result of the policy which he initiated. For the history of Charles I. as Charles V. Emperor of Germany, and of his action towards the Protestants and his campaigns in Italy and Germany, see CHARLES V. His reign was marked by the triumph of absolutism in Castile. His appointment of Flemings to high offices in Spain, and his exorbitant demands for supplies, led to the rising of the cities of Castile and to the war of the *comuneros*. These were vanquished at Villalar in 1521, and Toledo surrendered soon afterwards. A more popular movement in Valencia was crushed by the nobles of that province. Charles by timely appointments had separated the cause of the nobility from that of the cities; and on the refusal in 1538 of the nobles and clergy to share the burden of taxation these bodies ceased to be summoned to Cortes. The conquest of Tunis in 1535 was a brilliant feat of arms; the attempt on Algiers (1541) utterly failed. The troubles in Germany prevented Charles from following up these campaigns, which might have had results of great benefit to Spain. Worn out by disease, frustrated in all his plans, having failed in the election of his son Philip as emperor, Charles resigned first his hereditary dominions in 1555, and in 1556 abdicated the empire in favour of his brother Ferdinand, and his other crowns in favour of Philip, and retired to the monastery of Yuste, where he died in 1558.

When Philip II. (q.v.) ascended the throne of Spain her dominions were at their greatest. Spain, to which Portugal was added in 1580, Sicily, a great part of Italy, the Low Countries (Holland and Belgium), the whole of North America except the English and French possessions, the whole of South America after 1580, the Philippine and other islands in the East, and possessions in Africa formed the first empire on which it could be said that the sun never set. Philip had inherited the difficulties and complications of his father's policy without his father's ability. Dull, tenacious, yet irresolute, the type of a conscientious bigot, he lived ruthlessly up to his own ideal. He acted as the cham-

pion of orthodoxy in Europe; wherever the faith was in danger there would he protect it. He sacrificed everything to this. And he ruled alone, with no assistant body of councillors, with secretaries only. Well served he was by generals, ambassadors, admirals, by great men in all departments; he had the finest fleets and armies of his age; he never swerved from his purpose; he did not, like his father, retire when baffled, but died working in his life's cause to the end. His return to Spain in 1559 was marked by his presence at the autos de fé at Valladolid and Seville. He failed in his attempts on Tunis and Algiers, but raised the siege of Malta in 1565; he put down the rebellion of the Moriscos in 1568-71, and Don John of Austria gained for him in 1571 the great sea-fight of Lepanto, which stayed the advance of the Turks in the Mediterranean. The action of Philip in introducing the Inquisition (q.v.), popular among the lower classes in Spain, but abhorred elsewhere, the license of the Spanish soldiery, and the stern rule of Alba produced a revolt in Flanders in 1559, which led to the formation of the United Provinces in 1609 (see HOLLAND). The abilities of the regents and generals, especially of the Duke of Parma, who took Antwerp in 1585, gave for a time hope of reconquest; but the loss of the Armada (1588), and the diversion of Parma's forces against France (1590-92), made the contest hopeless. Henceforth Philip's power evidently declined. A quarrel with his secretary, Antonio Perez, led to an outbreak in Aragon and the restriction of its liberties in 1592. His communications and commerce with the colonies and with Flanders were continually threatened by Dutch and English corsairs. Philip had introduced the practice of raising money in Spain without consent of the Cortes, which was no longer regularly summoned. From ignorance of the true principles of political economy the very wealth of Spain hastened her decline. The false colonial policy of the time, with its restrictions and monopolies, gave all the profit of the commerce to contraband trade; the supply of only the precious metals made gold and silver cheaper in Spain than elsewhere and all other commodities dearer. Her rising industries died away. The bullion left her to purchase from foreigners things which she no longer produced and for which she had nothing else to give. Districts cultivated by the Moors became desert, population declined, and both the forces and resources of Spain by sea and land diminished yearly. Philip II. died September 13, 1598, in the palace of the Escorial.

Philip II. had reigned alone; with his son Philip III. began the reign of favourites, which continued with slight intermissions through both Austrian and Bourbon dynasties to the Revolution. The Duke of Lerma was the real sovereign. The ability of Spinola, who recovered Ostend in 1604, and of the captains trained in the school of Flanders upheld the prestige of the Spanish arms for a while; but her power was declining. The expulsion of the Moriscos, an agricultural population, in 1609 weakened her still more. In 1618 Lerma fell from power, but no improvement took place. Philip IV. (1621-65) possessed some taste for literature and art, but was as incapable of governing as his father. In the Thirty Years' War Spain fought on the side of the emperor, and her soldiers greatly contributed to his success, but she had no share in the profit. The government was in the hands of the Conde-Duke of Olivares, whose ambitious projects and wasteful expenditure introduced corruption everywhere. All offices became venal. The rights of the more independent kingdoms of Spain were violated, bringing about the revolt of Catalonia; the navy was almost destroyed by

the Dutch at Dunkirk in 1639; Rousillon was lost in 1642; with the battle of Rocroy (1643) departed the renown of the Spanish infantry, and the military supremacy henceforward belonged to France; Naples and Catalonia rose in revolt in 1648. In 1655 Jamaica was taken by the English. The marriage of the Infanta Maria Teresa to Louis XIV. and the peace of the Pyrenees (1659) assured to that monarch the supremacy in Spain which had formerly been exercised by Philip II. in France. After an inglorious struggle Portugal and all her colonies were lost in 1640. The reign of the childless Charles II. (1665-1700) closed the Austrian dynasty, a period of degradation surpassed only by that of the Bourbon Charles IV. a century later. Spain was considered as a prey to whichever of the great powers of Europe could lay hands on her. A brief war against France in alliance with Holland lost Franche Comté. Spain shared in the great wars of Louis XIV., but whoever else won she was always a sufferer; and the lack of a navy left her commerce and her richest colonies at the mercy of the buccaneers. A first treaty of partition of her dominions was made in 1698, followed by a second in 1700, after the death of the rightful heir, Leopold of Bavaria, in 1699. Contrary to his father's provisions, Charles left the throne to the grandson of Louis XIV. This did not avert the War of Succession (q.v.) and the losses which it occasioned. At the beginning of the 17th century the Spanish armies were the first in the world, her navy was the largest; at its close the latter was annihilated, her army was unable without assistance from Louis XIV. to establish the sovereign of her choice; population had declined from 8 to less than 6 millions, the revenue from 280 to 30 millions; not a single soldier of talent, not a statesman, remained to recall the glories of the age of Charles V. and Philip II.; the whole country grovelled in discontent at the foot of unworthy favourites raised to power by court intrigues, and dependent on a foreign prince.

The first of the Bourbon kings of Spain, Philip V. (q.v.), was proclaimed in Madrid, May 1700. He was accepted by the Cortes of Castile, but not by Aragon or Catalonia. His rival, the Archduke Charles, was supported by all the enemies of Louis XIV. The theatre of the War of Succession included Flanders, Germany, and Italy, as well as France and Spain and their colonies. In Flanders and Germany the English under Marlborough were victorious, but in Spain they fought with less success. Gibraltar was taken by Sir George Rooke in 1704, Valencia and Barcelona were occupied by Peterborough in 1705, and Philip was twice driven from Madrid. But with the aid of Berwick he won the battle of Almansa (1707), and Vendôme defeated Stanhope at Brihuega and Villaviciosa in 1710. The exhaustion of France, and the elevation of the archduke to the empire, led to the treaty of Utrecht in 1713. Catalonia submitted in 1714, and Spain was forced to adhere to the treaty, losing all her Italian possessions, Sardinia, Minorca, Gibraltar, and Flanders.

Philip V.'s first care was to alter the law of Spanish regal succession in accordance with the Salic law of France, a change productive of serious consequences later. Though during the war Philip had shown much spirit, a constitutional melancholy led him to resign his crown in 1724 to his son Louis, on whose death, after a reign of a few months, Philip resumed power. The entire government was in the hands of his second queen, Isabel Farnese, and her minister Alberoni. Their whole policy was directed to the establishment of her sons in Italy as duke of Parma and king of Naples and Sicily. In this she succeeded, but the gain was simply for the House of Bourbon; it

brought no advantage to Spain. To Philip V. succeeded his son Ferdinand VI. (1746-59). His choice of ministers was good, and his avoiding war gave the country an opportunity of internal development. This led to the greater reforms of his half-brother Charles III. (1759-88). He had already been successively duke of Parma and king of Naples and Sicily, and his was the most flourishing of all the Bourbon reigns. He brought with him his Italian ministers, Grimaldi and Esquilache, who made the policy of the early part of his reign too subservient to that of France. Afterwards he gathered round him the most intelligent Spaniards of his day. Superstitiously religious though he was in private life, his reign was yet notable for the expulsion of the Jesuits in 1757, for reasons which have never been clearly explained. The years 1764-66 were marked by reforms in the administration of the colonies, where great abuses existed. Only 840,000 dollars out of a revenue of 4 millions really entered the treasury. These revenues rose shortly from 6 million to 20 million dollars for Mexico alone. His home policy was equally successful: new manufactures were established, roads were improved, more beneficial commercial treaties were made, banks were introduced, and population increased with wealth. Through fear of the movement spreading to her own colonies, Spain wisely remained neutral during the war of independence of the United States. The foreign events of the greatest importance were a fruitless expedition to Algiers in 1775, the recovery of Minorca in 1782, and the fruitless siege and blockade of Gibraltar (1779-82). The great defect of this reign was that nearly all Charles's ministers were *afancesados*; their reforms were based rather on the theories of the French encyclopædists than on the real needs and the principles of liberty still existing in Spain. There was a wide gulf between the educated classes and the body of the nation. Charles IV. (1788-1808) retained for a short time his father's ministers; but they were soon replaced by Godoy, whose unbounded influence over Charles and his queen, limitless greed, and shameless subservience to the French, especially to Napoleon, brought the nation to the verge of ruin. He not only accumulated almost all offices in his own person, but in secret schemes with Napoleon bargained for himself half of Portugal as an independent kingdom, or a hereditary viceroyalty in America. On the outbreak of the French Revolution, in spite of ties of blood and of old treaties, Charles IV. was the last to protest against the overthrow of royalty and the execution of Louis XVI. A campaign was then begun on the Pyrenean frontier in 1793, with some success at first, changed to defeat as soon as the Republic could spare forces to turn against her southern neighbour. In 1795 the peace of Basel gained for Godoy his title of Prince of Peace; and the treaty of Ildefonso (1796) bound Spain to an offensive and defensive alliance with France against England. The result was disastrous. In 1797 Jervis won the naval battle of St Vincent; Trinidad was taken, and Cádiz bombarded. But Nelson was repulsed at Teneife (Teneiffe), Porto Rico was preserved, and the expeditions of Beresford and Whitelocke in La Plata eventually failed. The commerce and communications of Spain with her colonies was almost wholly destroyed. A scandalous quarrel between Charles IV. and his son Ferdinand (1807) augmented the hatred of the nation against Godoy. All three parties appealed to Napoleon for his arbitration and intervention. In view of the utter degradation of the crown many of the best men in Spain believed that a short rule by Napoleon might stem the tide of corruption. The royal family and the favourite attempted flight, but this was prevented by a

popular outbreak at Aranjuez. Godoy was hurled from power. Charles IV. abdicated in favour of his son, Ferdinand VII., March 17, 1808. French troops entered Madrid. Charles IV., his queen, and son Ferdinand, with Godoy, were summoned to Bayonne. There the crown was renounced by Ferdinand in favour of his father, who in turn ceded it to Napoleon. But on May 2 an unsuccessful outbreak in Madrid had begun the war of liberation, and Napoleon had to face a nation in arms. June 6, Joseph Bonaparte was proclaimed king of Spain. Nominally he reigned till 1813, but the Juntas, the representatives of the nation, acknowledged only the captive Ferdinand VII. For details of the French occupation of Spain, their forcible expulsion by Spanish, Portuguese, and English, see MOORE, WELLINGTON, PENINSULAR WAR, &c. While these operations were going on, the patriots were making great efforts to reform the government, and to give more real liberty to the people. The task was difficult; the absolutist party was still strong, and the liberals were divided; but the Constitution of Cádiz of 1812 is really the commencement of modern Spain. When Ferdinand returned in March 1814, he found the absolutists still powerful enough to enable him to reject the constitution to which he had sworn, to re-establish the Inquisition, and to remove all restrictions to his rule. An insurrection headed by Riego and Quiroga forced him to accept the Constitution from 1820 to 1823, but through the mistakes of the liberals, with the aid of 100,000 French soldiers under the Duc d'Angoulême, he regained his authority, and remained absolute master till his death. In December 1829 the childless Ferdinand married his fourth wife, Cristina of Naples. Up to this time his brother, Don Carlos, had been considered heir. In prospect of issue, Ferdinand promulgated (March 31, 1830) the pragmatic law of Charles IV., 1789, restoring the old law of Spanish succession. In September 1832 he revoked this sanction, but again recalled his revocation. Don Carlos was exiled to Portugal. April 4, 1833, Cortes acknowledged Ferdinand's daughter Isabella as heir to the throne, with her mother as regent. Ferdinand died September 29, 1833. During his reign the whole of Spanish continental America was lost (see PERU, &c.), and of all the vast colonies there remained only Cuba, Porto Rico, the Philippine, Caroline, and Mariana islands, Fernando Po, the Canaries, and a few ports and towns in Africa and the Straits. The opinion of Europe, which in 1823 had been conservative, and had enabled Ferdinand to regain absolutism by French help, had in 1833-40 become liberal, and this, with English help far more than the skill of her own armies, enabled Cristina to vanquish Don Carlos; but her government was far from strong, revolts and *pronunciamentos*, both by liberals and conservatives, were continually occurring. Monks were massacred in Madrid and Catalonia in 1834-35; church property was confiscated. The constitution of 1812, enlarged in 1836, was sworn by Isabella on attaining her majority in 1843. The marriage of the queen to her cousin, Francisco de Asís, and of her sister to the Duc de Montpensier, only weakened her position. Successive ministries rose or fell from power, all inefficient or corrupt. Narváez in 1844 showed some energy. O'Donnell conducted successfully a campaign in Morocco in 1859-60. On the whole, liberalism advanced; republicanism appeared after 1848. In disgust at corrupt administration the country accepted a *pronunciamento* by Prim and Topete at Cádiz in 1868. Isabella fled to France, and there resigned in favour of her son, Alfonso XII. The programme of the military leaders was simply destructive. A provisional government of two years (the chief event

of which was to furnish the pretext for the Franco-German war of 1870) ended in the choice of Amadeus (q.v.) of Savoy as king. In 1873 he resigned the crown. The republic which followed showed the wide differences between the Federalists and the conservative Republicans. This situation occasioned the second Carlist war, 1872-76 (see CARLISTS). On the waning of their cause, Isabella's son, Alfonso XII., was proclaimed king, December 29, 1874. February 27, 1876, Don Carlos withdrew to France. Mainly through the talents of his minister, Cánovas del Castillo, Alfonso's reign of eleven years (1874-85) was a time of relative prosperity and improvement, and enabled his queen Cristina quietly to succeed as regent for his posthumous son, Alfonso XIII., born May 17, 1886. During the regency, which lasted till 1902, liberal and conservative ministries alternated peacefully, while the influence of the church was considerably extended (though this led to the crisis with the Vatican in 1910). In Cuba (q.v.), however, there had been trouble and disaffection since 1895, intensified by the threatened interference of the United States, and by the mysterious blowing-up of the American warship *Maine* in Havana harbour in Feb. 1898. From April to August the United States and Spain were at war. Cuba was invaded by American troops, while the Spanish fleet was totally destroyed, part at Manila and part at Santiago. Spain surrendered Cuba, Porto Rico, and the Philippines, receiving £4,000,000 for the latter, while the sale to Germany of the Caroline, Pelew, and Ladrone Islands followed. Subsequent foreign policy has been in favour of a general rapprochement with Spanish America. In home politics, elections continued to be conducted and cabinets to be formed largely by corruption and intrigue. Much trouble has come from the separatists of Catalonia, who demand an autonomous state with its own parliament, executive, judicature, and official language. Centering mostly in Barcelona, a cosmopolitan and industrial town, there have been many grave disorders, strikes, and riots, notably in 1902, 1909, 1912, 1917, and 1919-20. An artificial trade prosperity at the beginning of the Great War (during which Spain remained strictly neutral) was followed by the inevitable reaction.

The situation in Morocco (q.v.) has been difficult ever since the Spanish-Rif campaign of 1894. The first Spanish-French agreement was drawn up in 1904, but German interference (especially at Agadir in 1911) raised further complications, making necessary the new agreement of 1912, which marked out the Spanish and French protectorates and the international zone of Tangier. In 1921 the Rif (q.v.) leader, Abd-el-Krim inflicted a crushing defeat on the Spanish forces at Anual, continued on the offensive, and in 1925 invaded the French protectorate. A determined Spanish and French campaign eventually brought about his overthrow in 1926. It was this 'running sore,' this wastage of men and money in Morocco, that furnished the occasion for the *coup d'état* of General Primo de Rivera in 1923. The army had always wielded considerable influence in politics, some of the *Juntas* or Committees of Defence acquiring great (and often unconstitutional) power, but hitherto the 'silent veto' had been exercised behind the scenes. The military directory of Primo de Rivera dissolved parliament, abolished the cabinet, established martial law, and set itself to reform the administration, at the same time suppressing all republican and separatist movements. In 1925 the directory gave way to a semi-civilian government with Primo de Rivera at the head. In the recent past, the illiteracy of the common people, the laxness of the executive in the carrying-out of laws, the lack of business initiative, and the absence of organisation

in schemes for housing, town-planning, railway-building, &c. (not to mention the political chaos of the 19th century) have very seriously retarded the development of the country. Spain has great natural resources, while her position in the intellectual world of the 20th century is assured by her brilliant achievements in literature, art, and music.

SPANISH LANGUAGE AND LITERATURE.—Three Romance Languages (q.v.) are still spoken in Spain: Castilian, generally known as Spanish; Catalan, a dialect of Provençal; and Galician, closely allied to Portuguese. Castilian, which has been deservedly called 'the noblest daughter of Latin,' is spoken, with slight local variations, by more than two-thirds of the population. The reason for its having to a great degree supplanted Catalan and Galician is to be found quite as much in political causes as in its own richness of vocabulary and stately measured cadence. Its chief characteristics are the purity of its vowel-sounds and the strong guttural, the origin of which is doubtful, though its introduction is undoubtedly modern. The Castilian vocabulary contains a large number of Arabic words chiefly connected with agriculture or science; Greek words, mostly of learned and modern introduction; the traces of Basque and Gothic are slight. The influence of French is very noticeable, particularly during the 18th and 19th centuries. Castilian is the form of Spanish spoken by some 60 millions in Mexico, Central and South America (excepting Brazil).

See on the subject generally, Grober, *Grundriss der Romanischen Philologie*; Diez, *Grammaire des Langues Romaines* (Fr. trans.); the admirable article by Morel-Fatio and Fitzmaurice-Kelly in the *Encyclopædia Britannica*; also Cejador y Frauca, *Historia de la Lengua y Lit. Castellana* (1915 et seq.); the Dictionaries of the Spanish Academy (1st ed. 1726); Spanish-English dictionaries by Neumann and Baret (1837), Velázquez (1878), Cuyas (1906), &c.; Grammars by Knapp (1887), Butler-Clarke (1892), Sanin Cano (1913), &c. For Catalan, Milá y Fontanals, *Estudios de la Lengua Catalana*. For Galician, Arce, *Gramática Galega* (Lugo, 1868).

Castilian Literature.—The earliest existing documents in Spanish belong to the first half of the 12th century. The first monuments of Spanish literature are poetical. The *Poema del Cid* (see CID), ascribed to the later half of the 12th century, is a typical *chanson de geste*; picturesque and spirited at times, it breathes the spirit of the turbulent age which produced it. Written in unformed and uncouth language, it displays a barbarous and irregular versification. The lines vary in length from twelve to sixteen syllables, and the same rhyme is carried on through long passages. To the 13th century belongs a body of religious poetry of tame character and slight merit. Gonzalo de Berceo is the first Spanish author whose name has come down to us. He wrote rhyming lives of saints and praises of the Virgin, which closely resemble in style, subject, and versification those of other monkish authors of his own and the succeeding century. The 13th century saw the formation of literary Castilian. To this

period belongs Alfonso the Wise, king of Castile (see ALFONSO X.), who left behind him a large and valuable body of works written either by himself or at his direction. The most important of these is the code of laws, with digressions on moral and political philosophy, known as *Las Siete Partidas*. This treatise, embodying anterior Gothic codes, has been the groundwork of all subsequent Spanish legislation; it forms also a most important monument of the language, which now for the first time appears as an instrument fitted for literary production. A collection of verse, mostly of a religious character, and undoubtedly belonging to this period, has been long a puzzle to scholars from the circumstance that, appearing as the work of Alfonso the Wise, it is written in the Galician dialect. Alfonso's literary tastes were shared by his nephew, Don Juan Manuel, author of several works of great interest which have come down to us, and of many others now unfortunately lost. He is best known by the *Conde Lucanor* or *Libro de Patronin*, a series of stories mostly of eastern origin, loosely connected together and with rhymed morals attached. The most original writer of the 14th century is Juan Ruiz, archpriest of Hita, a disreputable cleric, who relates his love adventures in poetical form, interlarding them quaintly with moral fables and religious hymns. In spite of great blemishes and frequently recurring obscene and blasphemous passages, the work is valuable from its vivacity and the excellent picture it gives of one side of life at the time. The verse is still that of the earlier poets, fourteen syllable lines, stanzas of four lines with one rhyme repeated. In prose these early centuries produced little that is worthy of note, as Latin was still much used. By the direction and, probably, under the supervision of Alfonso the Wise, was compiled the *Grande y General Historia*, extending from the creation nearly to his own times. This work was continued by official chroniclers, generally as a bare record of events, down to the time of Ferdinand and Isabella. Pedro Lopez de Ayala wrote the history of the kings under whom he lived in somewhat more picturesque and lively style than his predecessors; his *Rimado de Palacio* is a caricature of the different classes of society of his time, for studying which his high position and many adventures gave him admirable opportunities.

In the 15th century two new and important branches of Spanish literature appear—the Romances of Chivalry (*Libros de Caballerías*) and Ballads (*Romances*). The *Amadis de Gaula* (see AMADIS), first and best of books of chivalry, has come down to us in a translation from a Portuguese version, of which the original is lost. It is, however, certain that this is not the earliest form of the story in Spanish. The *Amadis* is not free from the exaggerations and stilted style that deface later books of its class, but, unlike them, it contains passages of great beauty, and, in spite of its being a translation, its language is generally dignified and pure. The popularity of the class was great; but successive authors rivalled one another in wild exaggeration and the frigid impossibility of the adventures of their heroes, who live under social conditions that have never existed, and in a world without geography. The Romance of Chivalry was dying a natural death when Cervantes gave it the *coup de grâce*. The origin of the Spanish ballads is very uncertain; they are probably of indigenous growth, as no striking parallels can be cited to support the theory that they are imitated from the poetry of the Moorish conquerors of Spain. The great mass of them was collected in the 16th and 17th centuries from the mouths of the people, but many of them are of much earlier date. Handed down orally from

generation to generation, they underwent considerable modification, and their language alone cannot be taken as a sufficient clue to their date. Their structure is characteristically Spanish; the lines may be considered either as octosyllabic or as of sixteen syllables with caesura; the same *asonante* or vowel-rhyme is continued throughout whole compositions. In subject these ballads range from sacred history to the Arthurian and Carolingian cycles, but the most valuable and interesting are those which celebrate the national heroes and the Moorish champions against whom they fought.

Thus far the works mentioned have been of purely national character or derived from sources common to the writers of the middle ages; but at the court of John II. the influence of Provençal literature began to make itself strongly felt, and a generation of stilted and affected poetasters arose encouraged by the king, who formed one of their number. The works of many authors of this school are collected in the celebrated *Cancionero de Baena*; with the exception of a few religious pieces they are of slight merit, but they succeeded in enriching Spanish with new lyric metres. At the end of the 15th century appeared the *Tragicomedia de Calisto y Melibea*, better known as the *Celestina*. It is said to be the work of two authors, but the wonderful evenness of its style makes this hard to believe. The *Celestina* partakes of the nature of novel and drama. Written entirely in dialogue, but at the same time immoderately long and unsuited for dramatic representation, it is unique amongst works of its time and country, being perfectly unaffected in style. Taking its subject from a side of life that must have been familiar to its authors, it neither shirks nor courts obscene details, but aims at and thoroughly succeeds in giving a true and animated picture, and at the same time enforcing a moral lesson. It soon became one of the most popular books in Spain, and was translated into most European languages.

It is probable that from Roman times the Drama (q.v.) never became extinct in Spain. It is mentioned in the *Siete Partidas*, and one of the earliest extant pieces of Spanish is a miracle-play, *El Misterio de los Reyes Magos*. The modern Spanish drama, however, must reckon its origin from the end of the 15th century, when Juan del Encina wrote *églogas* or *representaciones* of pastoral character, some of which were undoubtedly acted. Gil Vicente and Torres Naharro imitated and improved upon the methods of Encina, but Lope de Rueda, playwright and actor (fl. 1550), must be considered as the father of the Spanish dramatists, and as such he is mentioned by Cervantes. Continuing the pastoral drama of his predecessors, Rueda also wrote regular plays, divided into acts. In these the influence of the Latin stage is perceptible. The best part of Rueda's work consists of his spirited interludes (*entremeses*, *loas*) of a popular and burlesque character. Cervantes (q.v.) commenced his career as a dramatic author, but his two earlier pieces, *La Numancia* and *El Trato de Argel*, though finely conceived, were unsuccessful.

With the decay of the popularity of the romances of chivalry is coincident the rise of the novel in its different forms. In the *Diana Enamorada*, Montemayor and Gil Polo directly imitated the Italian. Cervantes and Lope de Vega each produced a novel of the kind, but the false and exaggerated sentiment and inferior verse to which the impossible shepherds generally treat one another in these compositions make it hard to understand the popularity which they undoubtedly enjoyed. Side by side with the pastoral novel, but with stronger growth, thrived the realistic *novela picaresca*, or rogue's story (see NOVELS), subsequently brought to perfection by Le Sage, who in his *Gil Blas* drew

largely upon his Spanish models. The earliest book of the kind is *Lazarillo de Tormes*, ascribed, apparently without reason, to Diego Hurtado de Mendoza (see MENDOZA), a poet and historian of the time of Charles V., at whose court he played a considerable part. *Lazarillo*, the hero, like his brethren of the other books of the class, is a poor boy of shady antecedents, who, by his own ingenuity and unscrupulousness, with varying fortune pushes his way, generally as a servant, amongst all classes of society. So admirable a vehicle for amusement and satire was not neglected, and *Guzmán de Alfarache*, *Marcos de Obregón*, *La Pícarra Justina*, and many others go to prove the popularity of this kind of story. A solitary and not very brilliant example of the historical novel at an early date is the *Guerras de Granada* by Hita.

Some of the older poets, amongst them the Marqués de Santillana, had imitated Italian models, but the influence of Petrarch and his school is most directly felt in Juan Boscán and Garcilaso de la Vega, who flourished in the first half of the 16th century. The latter in his *églogas* brought hendecasyllables to perfection in Spanish, and left at his early death a small collection of the most beautiful poetry in the language. An imitator of, and at times a translator from, Virgil and Petrarch, he is not unworthy of his models; the harmony of his verse is unsurpassed, unless it be by the *Coplas de Manrique*, probably one of the finest elegies extant.

Lyric poetry reached its culmination in the first half of the 16th century. Most of it is of religious character. In sublimity of conception and perfection of execution Herrera's (see HERRERA) odes and elegies are entitled to a very high place in European literature. Whilst Herrera sang of the victories and reverses of his time, Luis de León drew his inspiration from nature, solitude, and religious meditation. Sweetness of language never deserts him, but his productions are uneven in merit. The brothers Argensola (q.v.) owe their fame rather to good taste than to poetic inspiration. These writers come within the Spanish golden age, during which prose reached its highest development in the religious and mystic writings of Luis de León, Luis de Granada, St Teresa, and Juan de la Cruz, in the histories of Mariana (q.v.) and Solís, and in parts of the writings of Cervantes (see CERVANTES). The *Don Quixote*, with its quaint humour, rollicking fun, melancholy touches, and profound views of human nature, is deservedly, both at home and abroad, the best-known and best-loved book in Spanish. Unique amongst the works of its time, and far superior to the other efforts of its author, it belongs to no class, and has no successor in Spanish or any other literature. Cervantes' other works, the *Galatea*, *Persiles y Sigismunda*, *Viage del Parnaso*, dramatic works and novels, are read chiefly on account of the interest which must be felt for the author of *Don Quixote*.

Contemporary with Cervantes was Lope de Vega (see VEGA), the idol of his time, the 'prodigy of nature' (*monstruo de la naturaleza*), as he was called on account of the immense mass and great variety of his writings. Almost every branch of literature was familiar to him. Of dramas alone he wrote over 2000, besides a great body of lyric verse, epic and mock epic, novels both pastoral and of adventures, and criticisms. It is by his dramas that he is best known, and especially by those of cloak and sword (*capa y espada*). These within certain well-defined limits afford considerable scope for variety. The scene is invariably laid in some Spanish town. The principal characters are two lovers, whose adventures and somewhat stilted dialogue are parodied and relieved by those of their servants, one of whom

is generally the *gracioso* or buffoon, whose homely pleasantries sometimes jar disagreeably in the midst of fine and solemn passages. The metre of the Spanish drama is generally the same as that of the ballads; some variety, however, both of grouping of rhymes and of metre is admitted. A distinctive feature is the exceeding intricacy of the plots. This characteristic is so marked as to have led several critics to believe that a Spanish drama requires a Spanish audience to follow it intelligently. The great amount of the productions of Lope de Vega precluded all attempt at finish. His verse, however, is always flowing, and he generally attains success by thoroughly carrying out his own maxim that the drama is a purely popular form of literature, and that the only critics to be regarded are the mass of those who pay their money at the theatre-door. Calderón de la Barca (see CALDERÓN) outlived the golden age of the drama of his country. More philosophic, careful, and with a higher ideal than Lope, he is generally incapable of carrying out his gigantic enterprises, and is, broadly speaking, a poet of fine passages rather than a dramatic author of high merit. In attempting sublimity he frequently becomes bombastic and misty, and is deeply infected with the bad taste of his time. He perfected the *auto sacramental*, a religious play, or rather a dramatised theological discussion, in which such characters as Conscience, Free-will, Hope, and the cardinal virtues take part. On these, to modern taste, somewhat dull compositions, in which Christian theology is frequently jumbled up with pagan mythology, Calderón lavished a great deal of his best verse, and to them his reputation amongst his contemporaries was largely due. Equal to Lope or Calderón as dramatists, though inferior as poets, are Tirso de Molina (see TELLEZ) and Moreto. The former handled to perfection his native language, and is, more than any other, characteristically a Spaniard of his time. His defects are the want of a high ideal and the frequent coarseness of his language. Outside his own country he is chiefly known as the author who first dramatised the story of Don Juan Tenorio, the *Burlador de Sevilla*, a theme whose impressive nature he well knew how to take advantage of. Moreto is the most correct of Spanish dramatists, and his *Desdén con desdén* merits special mention, even in an age which produced, besides the authors already mentioned, Rojas and Alarcón (q.v.). The number of dramas produced at this time is almost incredible, and some, even of the anonymous ones, are such as in a less fertile age would have sufficed to found a reputation.

Spanish eloquence has always had a tendency to become bombastic; mannerisms and affectation of the worst kind have been mistaken for cultured style; extravagance of metaphor was rife even at the best period (see EUPHUISM); but when literature began to decay all these defects became more marked. The typical representative of this *culto* school is Luis de Góngora (see GÓNGORA), a poet who enjoyed great popularity in the golden age, and whose example probably did much to hasten a climax which had already become inevitable. In his youth he wrote simply and correctly short lyric pieces of great beauty. It is difficult to believe that this is the same Góngora who, a few years later, produced the *Soledades* and *Polyfemo*, poems so obscure, bombastic, and crammed with *concetti* that before his death they required lengthy commentaries. Amongst those who protested against the tendency of the times, whilst frequently allowing themselves to be carried away by it, was Francisco de Quevedo y Villegas (see QUEVEDO), the bitter satirist and writer of trenchant verse. Extremely versatile, his writ-

ings include erotic verse, light lyrics, essays on government, picaresque novels, and theological discussions. In his merits and defects he closely resembles Swift. The best known of his works are his *sueños*, or visions, in which the motives and manners of his time are held up to ridicule with a mastery and unsparing hand.

At the end of the 17th century the sun of Spanish glory set, and with it the sun of Spanish literature, so suddenly and completely as not to leave an afterglow behind it. Of the succeeding century only a few names deserve mention. Padre Isla (q.v.) in *Fray Gerundio* ridiculed the low ebb of education, and particularly of pulpit oratory, with wit and good sense worthy of a better age. Samaniego and Yriarte wrote some clever fables in the style of the inimitable La Fontaine. The Academy, founded during the first half of the 18th century, produced the magnificent dictionary which is its chief claim to the gratitude of scholars. When literature seemed at its lowest ebb, and nothing found favour unless slavishly imitated from the French, Moratín (q.v.) came to add one more name to the glorious list of dramatists.

The despotic rule of Ferdinand VII. (d. 1833) drove into exile practically all writers of liberal tendencies, but the successful production (1835) of the play, *Don Álvaro* by the Duque de Rivás, was a victory for romanticism. A new period of Spanish literature began, characterised by a direct realism (apt to degenerate into over-emphasis) and by a distinctly national (or more often, regional) spirit. The first of these regional novelists was Fernán Caballero, whose *Gaviota* is marked by keen personal observation, but the first half of the 19th century was rendered noteworthy by a group of poets: Espronceda, passionate and impetuous; Zorrilla, more restrained, but also more facile; Becquer, author of some charming lyrics; and Campoamor, whose delicate craftsmanship found expression in *Doloras*. Echegaray produced many plays of the sentimental type, while the poet Núñez de Arce won fame with his virile *Gritos del combate*. The development of the novel (often relying more on characterisation rather than on plot), however, has been the predominant feature of modern Spanish literature, and *Pepeita Jiménez* (1874) of Valeia and *El Sombrero de tres picos* (1874) of Alarcón still remain two of the most outstanding examples. Four novelists, in particular, connect the 19th with the 20th century: Pereda, almost reactionary in spirit, described the picturesqueness and rough grandeur of Santander; Emilia Pardo Bazán wrote delightfully of Galicia; Pérez Galdós, who has been compared to Dickens in his development of characters and in his love of the fantastic, helped to form a Spanish national consciousness with his huge series of historical novels, *Episodios Nacionales*; while Valdés interprets Asturias with a keen sense of humour and psychological understanding. There are four novelists belonging more particularly to the 20th century: the forcible Blasco Ibáñez, who is at his best in describing the humble life of Valencia, devotes himself in some of his later works to controversial social problems, but in some respects is too much influenced by the French naturalistic school; intense energy is also characteristic of the Basque, Pío Baroja, whose novels give a vivid and truthful presentation of life, but are somewhat unequal in construction; 'Azorín,' also a good critic, draws homely scenes with great detail and delicacy; but the art of Miró, equally sensitive, is almost more spontaneous. Ayala and Valle Inclán are both novelists and poets; the former (from Asturias) views life from an earnest detached point of view, while the style of the latter (from Galicia) is graceful, rhythmical, and subtle. The novelist León and the poets Jiménez and Asunción

Silva are the best of the younger school, but on the whole, the influence of the French *symbolistes* has been very penetrating. In the field of drama, the cosmopolitan Benevente, a Nobel prize-winner, with his great powers of vital character-drawing, has a worthy successor in Martínez Sierra. The Quintero brothers specialised in the writing of comedies, often for the *género chico* (short plays or sketches with songs and music). As regards scholarship and learning, two names stand out brilliantly in the 19th century—those of Mila y Fontanals and of Menéndez y Pelayo; while the philosophers Unamuno and Ortega y Gasset, both men of extremely wide culture, and the critic Menéndez Pidal, belong more to the 20th century. Periodic literature of a not very high order is abundant. There has always been considerable literary activity in Spanish America, but few writers of any special importance appeared before the Nicaraguan, Rubén Darío (q.v.), one of the most brilliant of the modern poets, with a mastery of technique allied to genuine lyrical powers. The Uruguayan, Rodó, specialised in æsthetic criticism.

Catalan Literature.—The intercourse between Catalonia and Provence has been great from the earliest times. The troubadours of Provence carried with them across the Pyrenees their own language as well as their own poetical forms. Their influence may be seen in the works of Raymond Lully, whose poem 'Despair' (*Lo Descomort*) is deeply impregnated with their mannerisms. At the later end of the 14th century a consistory of the *gay saber* was founded at Barcelona in imitation of the one already existing at Toulouse. From this may be dated the partial emancipation of Catalan verse. Two Valencian poets distinguished themselves in their native language. Ausiàs March, whose songs of love and songs of death are fine in spite of intentional obscurity, and Jaume Roig, whose bitter satire, *The Ladies' Book*, is supposed to contain details of his own life. Roig died in 1478, and at the union of Castile and Aragon Catalan sank to the position of a dialect. In prose the principal monuments of old Catalan are the works of Lully, including the interesting *Book of the Order of Knighthood*; the *Chronicles*, some of which are interesting both in matter and manner, especially that of Ramon Muntaner; and one romance of chivalry entitled *Tirant lo Blanch*, an exaggerated example of the defects of the class. In the 19th century a successful movement (not unconnected with politics) was set on foot to make Catalan, which had come from the Middle Ages virtually unchanged, a literary and not merely a popular language. Some of the verse of Verdaguer is very charming and natural, while more recent poets are Maragall, Carner, and López-Picó. The shadow shows of Robreño at the beginning of the 19th century can be said to have started the modern Catalan theatre, of which the most vigorous and dramatic exponents have been Guimerà, Gaul, and Rusiñol, while contemporary prose is well represented by Eugen d'Ors.

In Galician, which has never been a literary language, few books exist, with the exception of collections of popular songs.

CASTILIAN.—The standard English history of Spanish literature is that of Fitzmaurice-Kelly (new ed. 1926, superseding all former editions), but see also the general histories by Ticknor (6th ed. 1888), Butler-Clarke (2d ed. 1909), Ford (1919), and Northup (1925), all in Eng.; by Becker (1904, in Ger.); by Castro (1890), César Barja (1923-24), and Hurtado and Palencia (2d ed. 1925), all in Span. For the period up to the 16th cent. see the work by Amador de los Ríos (1861-65), for the Middle Ages, the work by Wolf (1859, in Ger.), and for contemporary literature, works by Mandariaga (1923) and A. F. G. Bell (1925), in Eng. For the drama in the time of Lope de Vega, in the 17th cent., and in contemporary

times respectively, see works by Rennert (1909, in Eng.), Morel-Fatio (2d ed. 1923, in Span.) and González-Blanco (1917, in Span.), as well as general histories by Castel (1882, in French) and Schaffer (1890, in Ger.). See also various books by Menéndez y Pelayo, including *Orígenes de la Novela* (1905-7) and *Historia de la Poesía Castellana* (1911-13). There are anthologies by Ford (1901), Fitzmaurice-Kelly (1913), and Farnell (1920); and histories of Spanish-American literature by Menéndez y Pelayo (1911-13, in Span.) and Coester (1917, in Eng.).

CATALAN.—See Mila y Fontanals, *De los Trovadores* (1861); Tubino, *Historia del renacimiento contemporáneo* (1880); Denk, *Altatalanische Litteratur*; histories by Rubió y Ors (1880), d'Oliver (1919), and studies on the drama by Urquiza (1911), Curet (1919), all in Spanish; anthology by Amade (1908).

Spalato, or less correctly SPALATRO (Slav. *Split*), the busiest town of Dalmatia, stands on the Adriatic, 160 miles SE. of Fiume. Here in a beautiful situation the Emperor Diocletian built a colossal palace (*Salonæ Palatium*, whence perhaps Spalato, though more probably from *ἡ παλάτιον*), to which he retired when he abdicated the throne in 305. The palace faced the sea, looking southwards; its walls were from 570 to 700 feet long and 50 to 70 feet high, and enclosed an area of 9½ acres. It stood square like a Roman camp, and had a gate in the middle of each side, and was of the most solid construction. Architecturally it is of the highest interest in that it contains several features that presage the architectural styles and devices of modern times. Inside the palace the roads connecting the gates crossed at right angles in the middle, and two of the four courts thus formed were each occupied by a temple (or similar building), one to Æsculapius, the other to Jupiter. So at least says an ancient tradition, though some modern authorities claim the latter, and others the former, as the mausoleum of the emperor. The temple of Jupiter is externally an octagon with a colonnaded peristyle and internally a circle covered by a dome. Where the projecting portico was built there now stands a tower built in the 14th and 15th centuries, thoroughly restored in 1891-92. Since the year 650 this temple has been a Christian cathedral; it contains a magnificent marble pulpit. The interior was extensively restored in the years immediately preceding 1855. The other temple is used as a baptistery; it is of small size and rectangular in shape. All the interior buildings and nearly all the exterior walls of this gigantic palace are still standing in a fairly good state of preservation. But the interior was converted into a town in 639 by the citizens of Salona (q.v.) who escaped the destruction of their town by the Avars, and it has been occupied ever since. The existing city of Spalato lies, more than half of it, outside the palace walls. It contains a museum rich in the remains of Salona, and has a lively trade; the Lasva railway (1895-97) connecting it with Bosnia and the Danubian lands. Its industries embrace the manufacture of liqueurs (rosoglio and maraschino), bricks, ropes, &c. Pop. 25,000. See ROMAN ARCHITECTURE; and books on the palace by R. Adam (in Eng. 1864) and G. Niemann (in Ger. 1910).

Spalding, a Dutch-looking town on the Welland in Lincolnshire, 14 miles SW. of Boston, with a fine church (Decorated and Perpendicular), built in 1284 and restored by Sir G. Scott. A castle and a monastery existed here prior to the Conquest. The grammar-school, of which Bentley was master in 1682, was founded in 1568; new school buildings were erected in 1881. Ayscoughfee Hall, dating originally from 1420, was the residence of the antiquary Maurice Jolinson, who helped to found the Society of Antiquaries and the Spalding

Gentlemen's Society (1710; resuscitated in 1889). Spalding lies in the centre of the fertile Fen District (see BEDFORD LEVEL), and has an active trade in agricultural produce. The river is navigable up to the town for vessels of 80 tons. Pop. 14,000.

Spalding, JOHN (fl. 1624-45), was the commissary clerk of Aberdeen and diaist, after whom is named a well-known northern Book-club (q.v.).

Spallanzani, LAZARO, naturalist and traveller, was born at Scandiano, in the duchy of Modena, Italy, on 12th January 1729. After studying, at Reggio di Modena and Bologna, natural science, mathematics, the classical tongues, law, and other subjects, he was in 1754 appointed to the chair of Logic, Metaphysics, and Greek at Reggio, and soon afterwards was transferred to Modena. But he took the greatest interest in natural history and physiological questions. Amongst other things his attention was directed to the doctrine of spontaneous generation propounded by Needham and Buffon, which after careful study and experiment he overturned. On the re-establishment of the university of Pavia Spallanzani was appointed (1768) professor of Natural History and keeper of the museum, which he greatly enriched with fishes, crustacea, and testacea, the fruits of his numerous excursions. In 1785-86 he spent nearly a twelvemonth in Turkey engaged in scientific observation, and during the year 1788 visited Naples whilst Vesuvius was in eruption, the Lipari Isles, and Sicily, and wrote an account of his inquiries, *Viaggi alle due Sicilie* (6 vols. 1792). He died of apoplexy, 11th February 1799. In *Dissertationi de Fisica Animale e Vegetale* (2 vols. 1780) he clearly demonstrated the true physiological nature of digestion, and established, on the basis of experiment, the respective functions of the spermatozoa and the ovum in reproduction.

Span, a measure of length, being the distance between the tips of the thumb and little finger when the fingers are expanded to their fullest extent. This space averages about 9 inches, which accordingly is the fixed measure given to the span.

Spandau, a town and first-class fortress of Prussia, since 1920 part of Berlin, is situated at the confluence of the Havel and the Spree. The principal defence of the capital on the west side, it has very strong modern fortifications, including a citadel. In the 'Julius tower' of this structure was preserved in gold the 'Reichskriegsschatz' of £6,000,000 that the government, according to a law of 11th November 1871, kept in reserve for a great war. Spandau has government munition works and an arsenal. Pop. (1875) 27,630; (1890) 44,611; (1910) 84,855; (1919) 95,474. One of the oldest towns of Brandenburg, it was a favourite residence of the electors. It surrendered to the Swedes in 1634, to the French in 1806, and in 1813 to the Prussians.

Spanheim, FRIEDRICH, theologian, was born at Amberg, January 1, 1600; studied at Heidelberg and Geneva; visited Paris and England; was appointed in 1631 to the chair of Theology at Geneva, in 1641 at Leyden; and died there, April 30, 1648. He contributed to the controversy with Amyrant *Disputatio de gratia universalis* (1644), &c.—EZECHIEL SPANHEIM, son of the foregoing, was born at Geneva, December 7, 1629, studied at Leyden, and was appointed professor of Rhetoric there in 1651. He next became tutor to the sons of the Elector Palatine, and with them travelled in Italy and Sicily. In 1665 he represented the Palatinate and Brandenburg as resident in England; in 1680 he went for nine years to Paris as ambassador extraordinary. He took part in the peace of Ryswick, later went on missions both to Paris and

London, and died at the latter, 7th November 1710. He had great learning in the history of ancient law and in numismatics, and his *Dissertationes de usu et præstantia numismatum antiquorum* (best ed. 1706-16) and *Orbis Romanus* (1704) made his name widely known.—FRIEDRICH SPANHEIM, his brother, was born at Geneva, May 1, 1632, studied at Leyden, was appointed to the chair of Theology at Heidelberg in 1655, at Leyden in 1670, and died there, May 8, 1701. He defended Calvinism against Descartes and Cocceius. His collected works fill 3 volumes (1701-3).

Spaniel, one of the longest established breeds of dogs. Dr Caius gives a description of the spaniel in his treatise *Of Englishe Dogges* (1576). The working spaniel may be divided into the Clumber, the Sussex, and the Field Spaniel. The clumber derives his name from the estate of the Duke of Newcastle, who originally imported them from the kennel of the Duc de Noailles, and bred them for many years at Clumber Castle (q.v.). The pure breed was guarded with jealousy. Clumbers are usually worked in a team of four or five; as they generally hunt in silence, they are extremely useful in thick cover, the game not being alarmed without cause. In appearance the clumber is a handsome lemon and white dog, short in the leg, long in body, coat like a setter, a massive head with large drooping ears.

The Sussex is also a variety of long standing, though the pure breed was only resuscitated in 1870 with great difficulty. In colour the Sussex should be a 'golden-liver' or brown, otherwise it closely resembles the clumber.

The Black Spaniel is bred mainly from Sussex blood. The 'cocker' and the 'springer' are names indiscriminately applied to field spaniels of unknown breeding; they are generally liver and white, and are probably cross-bred Sussex.

Though there are records of the existence of an English water-spaniel, yet the breed has been entirely eclipsed by the Irish water-spaniel. The Irish dog resembles a large poodle in face and size, an untrimmed coat curling all over the body; in colour it should be a reddish liver.

Toy Spaniels, though identical in name, have little in common with the working spaniel. They are divided into the black-and-tan King Charles, first brought into notice by Charles II., and the red and white Blenheim, established by the Duke of Marlborough. The toy spaniel should not weigh more than 10 lb., and should have a short turned-up face like a pug-dog. From their long coats and small size these dogs are only fitted for pets, but are bright and cheery in disposition.

Spanish Fly. See CANTHARIDES.

Spanish Legion. See EVANS (DE LACY).

Spanish Main (i.e. *main-land*), a name given to the north coast of South America from the Orinoco to Darien, and to the shores of the former Central American provinces of Spain contiguous to the Caribbean Sea. The name, however, is often used of the Caribbean Sea itself, especially in connection with the Buccaneers (q.v.).

Spanish Marriages. See GUIZOT.
